> Apache Iceberg uses an optimistic concurrency model along with conflict detection to arbitrate write transactions. With optimistic concurrency, user and compaction transactions can conflict causing transactions to fail. If conflicts occur, compaction jobs will retry on failure. It is recommended that your pipelines also use retry logic to overcome transactions that fail from conflicting operations.

Considerations for snapshot management

The following considerations apply to snapshot management. For more information about snapshot management, see the section called "Table maintenance".

- Snapshots will be preserved only when both criteria are satisfied: the minimum number of snapshots to keep and the specified retention period.
- Snapshot management deletes expired snapshot metadata from Apache Iceberg, preventing time travel queries for expired snapshots and optionally deleting associated data files.
- Snapshot management does not support retention values you configure as Iceberg table properties in the `metadata.json` file or through an `ALTER TABLE SET TBLPROPERTIES` SQL command, including branch or tag-based retention. Snapshot management is disabled when you configure a branch or tag-based retention policy, or configure a retention policy on the `metadata.json` file that is longer than the values configured through the `PutTableMaintenanceConfiguration` API. In these cases S3 will not expire or remove snapshots and you will need to manually delete snapshots or remove the properties from your Iceberg table to avoid storage charges.
- Snapshot expiration does not use `unreferencedDays` (a setting for unreferenced file removal) or evaluate an object's creation time. When snapshot expiration removes the last snapshot reference to an object, Amazon S3 immediately marks the object as noncurrent, regardless of its age. Amazon S3 permanently deletes the object after the configured `nonCurrentDays` period.

Considerations for unreferenced file removal

The following considerations apply to unreferenced file removal. For more information about unreferenced file removal, see the section called "Table bucket maintenance".

- Unreferenced file removal deletes data and metadata files that are no longer referenced by Iceberg metadata if their creation time is before the retention period.
- **Delayed commits** – Workloads such as high-throughput streaming pipelines can create data objects before a commit adds references to those objects in a table snapshot. Configure `unreferencedDays` to be longer than the maximum expected time between object creation and successful commit completion, including processing delays and retries.

  If an object reaches the configured `unreferencedDays` age before its commit completes, Amazon S3 marks the object as noncurrent because no snapshot references it yet. If a later commit then references that object, queries and maintenance operations that read it fail. Amazon S3 permanently deletes the noncurrent object after the configured `nonCurrentDays` period, and the object cannot be recovered.

S3 table and table buckets maintenance operations limits and related APIs

Maintenance operation	Property	Configurable at table bucket level?	Configurable at table level?	Default value	Minimum value	Related Iceberg maintenance routine	Controlling S3 Tables API
Compaction	`targetFi` `eSizeMB`	No	Yes	512MB	64MB	`rewriteDa` `taFiles`	PutTableMaintenanceConfiguration
Snapshot management	`minimumSr` `apshots`	No	Yes	1	1	`ExpireSna` `pshots` `retainLas` `t`	PutTableMaintenanceConfiguration
Snapshot management	`maximumSr` `apshotAge`	No	Yes	120 hours	1 hour	`ExpireSna` `pshots` `expireOld` `erThan`	PutTableMaintenanceConfiguration

Maintenance operation	Property	Configurable at table bucket level?	Configurable at table level?	Default value	Minimum value	Related Iceberg maintenance routine	Controlling S3 Tables API
Unreferenced file removal	`unreferencedDays`	Yes	No	3 days	1 days	`deleteOrphanFiles`	PutTableBucketMaintenanceConfiguration
Unreferenced file removal	`nonCurrentDays`	Yes	No	10 days	1 days	N/A	PutTableBucketMaintenanceConfiguration

Note

S3 Tables applies the parquets row-group-default size of 128 MB.

Cost optimization for tables with Intelligent-Tiering

You can automatically optimize storage costs for tables by using S3 Intelligent-Tiering. The S3 Tables Intelligent-Tiering storage class automatically moves data to the most cost-effective access tier when access patterns change. When you use S3 Intelligent-Tiering, data accessed less frequently is automatically moved to lower-cost tiers, and moved back to the Frequent Access tier whenever you access it again.

All data is moved between tiers without retrieval fees, performance impact, or changes to availability. Additionally, table maintenance operations such as compaction are optimized based on access patterns, processing only actively accessed data in the Frequent Access tier while reducing maintenance costs on less frequently accessed data in lower-cost tiers.

Topics

- S3 Tables Intelligent-Tiering access tiers
- Auto-tiering behavior with S3 Intelligent-Tiering
- Specifying S3 Intelligent-Tiering as your storage class
- Monitoring storage usage

S3 Tables Intelligent-Tiering access tiers

When your table is stored in the S3 Intelligent-Tiering storage class, Amazon S3 continuously monitors access patterns and automatically moves table data between access tiers.

Tiering happens at the individual file level, so a single table can have files in different tiers based on access patterns. Table data is automatically moved to one of the following access tiers based on access patterns:

- **Frequent Access**: The default tier for all files. Files in other tiers automatically move back to the Frequent Access tier when accessed.
- **Infrequent Access**: If you do not access a file for 30 consecutive days, it moves to the Infrequent Access tier.
- **Archive Instant Access**: If you do not access a file for 90 consecutive days, it moves to the Archive Instant Access tier.

All tiers provide millisecond latency, high throughput performance, and are designed for 99.9% availability and 99.999999999% durability.

Auto-tiering behavior with S3 Intelligent-Tiering

The following actions constitute access that automatically moves files from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier:

- Any read or write operations on table data or metadata files using `GetObject`, `PutObject`, or `CompleteMultipartUpload` actions
- `LoadTable` or `UpdateTable` actions using Iceberg REST API Operations
- S3 Tables replication operations

Other actions don't constitute access that automatically moves files from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier.

> **Note**
>
> Files smaller than 128 KB are not eligible for auto-tiering and remain in the Frequent Access tier. Compaction may combine these files into fewer, larger objects and commit them back to your table as a new snapshot. The newly compacted files become eligible for auto-tiering if the new file is 128 KB or larger.

Table maintenance behavior

Automatic table maintenance operations performed by Amazon S3, such as snapshot management, unreferenced file removal, and record expiration, continue to run on your tables regardless of tier. Compaction runs only on files in the Frequent Access tier, optimizing performance for frequently accessed data while reducing maintenance costs on data in lower-cost tiers.

Maintenance operations do not affect the access tier of files in your table. Reads performed by maintenance operations do not cause files to change tiers. However, if a maintenance operation, such as compaction or record expiration, writes a new file, that file is created in the Frequent Access tier.

> **Note**
>
> Because compaction only processes files in the Frequent Access tier, delete operations on data in lower-cost tiers create delete files that are not automatically compacted. These delete files become eligible for compaction when the associated data files are accessed and move back to the Frequent Access tier. For tables that are not frequently accessed, you can manually run compaction using Amazon EMR to compact these delete files with their associated data files. For more information, see Maintaining tables by using compaction. You can monitor file growth in your table using Amazon CloudWatch metrics to determine when manual compaction may be beneficial.

Specifying S3 Intelligent-Tiering as your storage class

By default, all tables are created in the S3 Standard storage class and cannot be moved to S3 Intelligent-Tiering. To use S3 Intelligent-Tiering, you must specify it at table creation. You can also

set S3 Intelligent-Tiering as the default storage class for your table bucket to automatically store any new tables created there in the S3 Intelligent-Tiering storage class.

Specifying S3 Intelligent-Tiering for table buckets

You can specify S3 Intelligent-Tiering as the default storage class when creating a new table bucket by using the `storage-class-configuration` header with the `CreateTableBucket` operation.

To check the default storage class on an existing table bucket, use the `GetTableBucketStorageClass` operation. To modify the default storage class of an existing table bucket, use the `PutTableBucketStorageClass` operation.

> **Note**
>
> When you modify the default storage class on a table bucket, that setting applies only to new tables created in that bucket. The storage class for pre-existing tables is not changed.

Specifying S3 Intelligent-Tiering for tables

You can specify S3 Intelligent-Tiering as the storage class when creating a new table using the `storage-class-configuration` header with the `CreateTable` operation.

If you do not specify a storage class at table creation, the table is created in the default storage class configured on the table bucket at that time. Once a table is created, you cannot modify its storage class.

To check the default storage class on an existing table bucket, use the `GetTableBucketStorageClass` operation.

Monitoring storage usage

You can view your storage usage breakdown by access tier in the AWS Cost and Usage Reports for your account. For more information, see Creating Cost and Usage Reports in the *AWS Data Exports User Guide*.

The following usage types are available in your billing reports:

Usage Type	Unit	Granularity	Description
region-Tables-TimedStorage-INT-FA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the S3 Intelligent-Tiering Frequent Access of S3 Intelligent-Tiering storage
region-Tables-TimedStorage-INT-IA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the S3 Intelligent-Tiering Infrequent Access of S3 Intelligent-Tiering storage
region-Tables-TimedStorage-INT-AIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the S3 Intelligent-Tiering Archive Instant Access of S3 Intelligent-Tiering storage
region-Tables-Requests-	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Tables Intelligent-Tiering objects

Usage Type	Unit	Granularity	Description
INT-Tier1			
region-Tables-Requests-INT-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests for S3 Tables Intelligent-Tiering objects

Table namespaces

When you create tables within your Amazon S3 table bucket, you organize them into logical groupings called *namespaces*. Unlike S3 tables and table buckets, namespaces aren't resources. Namespaces are constructs that help you organize and manage your tables in a scalable manner. For example, all the tables belonging to the human resources department in a company could be grouped under a common namespace value of `hr`.

To control access to specific namespaces, you can use table bucket resource policies. For more information, see the section called “Resource-based policies”.

The following rules apply to table namespaces:

- Each namespace must be unique within a table bucket.
- You can create up to 10,000 namespaces per table bucket.
- Each table name must be unique within a namespace.
- Each table can have only one level of namespaces. Namespaces can't be nested.
- Each table belongs to a single namespace.
- You can move your tables between namespaces.

Table namespaces are referred to as databases in various AWS services and query engines. The following table maps the terminology used for S3 Tables namespaces to some common engines and services.

Service or Engine	Terminology
AWS Lake Formation	Database
AWS Glue Data Catalog	Database
Athena	Database
Spark	Namespace

Topics

- Creating a namespace
- Delete a namespace

Creating a namespace

A table namespace is a logical construct that you group tables under within an Amazon S3 table bucket. Each table belongs to a single namespace. Before creating a table in a table bucket, you must create a namespace to group tables under. You can create a namespace by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), Amazon S3 REST API, AWS SDKs, or integrated query engines.

Namespace names

The following naming rules apply to namespaces:

- Names must be between 1 and 255 characters long.
- Names can consist only of lowercase letters, numbers, and underscores (_). Underscores aren't allowed at the start or end of namespace names.
- Names must begin and end with a letter or number.
- Names must not contain hyphens (-) or periods (.).
- A namespace must be unique within a table bucket.
- Namespace names must not start with the reserved prefix `aws`.

For more information about valid namespace names, see Naming rules for tables and namespaces.

Using the S3 console and Amazon Athena

The following procedure uses the **Create table with Athena** workflow to create a namespace in the Amazon S3 console. If you don't want to also use Amazon Athena to create a table in your namespace, you can cancel the workflow after creating your namespace.

To create a namespace

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that you want to create a namespace in.
4. On the bucket details page, choose **Create table with Athena**.
5. In the **Create table with Athena** dialog box, choose **Create a namespace**, and then choose **Create namespace**.
6. Enter a name in the **Namespace name** field. Namespace names must be 1 to 255 characters and unique within the table bucket. Valid characters are a–z, 0–9, and underscores (_). Underscores aren't allowed at the start or end of namespace names.
7. Choose **Create namespace**.
8. If you also want to create a table, choose **Create table with Athena**. For more information about creating a table with Athena, see the section called "Using the S3 console and Amazon Athena". If you don't want to create a table right now, choose **Cancel**.

Using the AWS CLI

This example shows how to create a table namespace by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables create-namespace \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-bucket1 \
    --namespace example_namespace
```

Using a query engine

You can create a namespace in an Apache Spark session connected to your Amazon S3 table buckets.

This example shows you how to create a table by using CREATE statements in a query engine integrated with S3 Tables. To use this example, replace the *user input placeholders* with your own information.

```
spark.sql("CREATE NAMESPACE IF NOT EXISTS s3tablesbucket.my_namespace")
```

Delete a namespace

Before you delete a table namespace from an Amazon S3 table bucket, you must delete all tables within the namespace, or move them under another namespace. You can delete a namespace by using the Amazon S3 REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or integrated query engines.

For information about the permissions required to delete a namespace, see DeleteNamespace in the *Amazon Simple Storage Service API Reference*.

Using the AWS CLI

This example shows you how to delete a table namespace by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables delete-namespace \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-bucket1 \
    --namespace example_namespace
```

Tables in S3 table buckets

An S3 table represents a structured dataset consisting of underlying table data and related metadata. This data is stored inside a table bucket as a subresource. All tables in a table bucket are stored in the Apache Iceberg table format. Amazon S3 manages maintenance of your tables through automatic file compaction and snapshot management. For more information, see Maintenance for tables.

To make tables in your account accessible by AWS analytics services, you integrate your Amazon S3 table buckets with AWS Glue Data Catalog. This integration allows AWS analytics services such as Amazon Athena and Amazon Redshift to automatically discover and access your table data.

When you create a table, Amazon S3 automatically generates a warehouse location for the table. This is a unique S3 location that stores objects associated with the table. The following example shows the format of a warehouse location:

```
s3://63a8e430-6e0b-46f5-k833abtwr6s8tmtsycedn8s4yc3xhuse1b--table-s3
```

Within your table bucket, you can organize tables into logical groupings called namespaces. For more information, see Table namespaces.

You can rename tables, but each table has its own unique Amazon Resource Name (ARN) and unique table ID. Each table also has a resource policy attached to it. You can use this policy to manage access to the table.

Table ARNs use the following format:

```
arn:aws:s3tables:region:owner-account-id:bucket/bucket-name/table/table-id
```

By default, you can create up to 10,000 tables in a table bucket. To request a quota increase for table buckets or tables, contact Support.

Amazon S3 supports the following types of tables in table buckets:

Customer tables

Customer tables are tables that you can read and write to. You can retrieve data from these tables using integrated query engines. You can insert, update, or delete data within them by using S3 API operations or integrated query engines.

AWS tables

AWS tables are read-only tables that are generated by an AWS service on your behalf. These tables are managed by Amazon S3 and can't be modified by any IAM principal outside of Amazon S3 itself. You can retrieve information from these tables, but you can't modify the data in them. AWS tables include S3 Metadata tables, which contain metadata that's captured from the objects within an S3 general purpose bucket. For more information, see Discovering your data with S3 Metadata tables.

- Managing table policies
- Using tags with S3 tables

Creating an Amazon S3 table

An Amazon S3 table is a subresource of a table bucket. Tables are stored in the Apache Iceberg format so that you can work with them by using query engines and other applications that support Apache Iceberg. Amazon S3 continuously optimizes your tables to help reduce storage costs and improve analytics query performance.

When you create a table, Amazon S3 automatically generates a *warehouse location* for the table. A warehouse location is a unique S3 location where you can read and write objects associated with the table. The following example shows the format of a warehouse location:

```
s3://63a8e430-6e0b-46f5-k833abtwr6s8tmtsycedn8s4yc3xhuse1b--table-s3
```

Tables have the following Amazon Resource Name (ARN) format:

```
arn:aws:s3tables:region:owner-account-id:bucket/bucket-name/table/table-id
```

By default, you can create up to 10,000 tables in a table bucket. To request a quota increase for table buckets or tables, contact Support.

You can create a table by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or query engines connected to your table buckets.

When you create a table you can specify the encryption settings for that table, unless you are creating the table with Athena. If you don't specify encryption settings the table is encrypted with the default settings for the table bucket. For more information, see Specifying encryption for tables.

Prerequisites for creating tables

To create a table, you must first do the following:

- Create a table bucket.
- Create a namespace in your table bucket.
- Make sure that you have AWS Identity and Access Management (IAM) permissions for `s3tables:CreateTable` and `s3tables:PutTableData`.
- **Note**

  If you are using SSE-KMS encryption for your table, you need permissions for `s3tables:PutTableEncryption`, and `DescribeKey` permission on the chosen AWS KMS key. Additionally the AWS KMS key you use needs to grant S3 Tables permission to perform automatic table maintenance. For more information, see Permission requirements for S3 Tables SSE-KMS encryption

For information about valid table names, see Naming rules for tables and namespaces.

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to create a table with Amazon Athena. If you haven't already created a namespace in your table bucket, you can do so as part of this process. Before performing the following steps, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see the section called “Integrating S3 Tables with AWS analytics services”.

> **Note**
>
> When you create a table using Athena that table inherits the default encryption settings from the table bucket. If you want to use a different encryption type you need to create the table using another method.

To create a table

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that you want to create a table in.
4. On the bucket details page, choose **Create table with Athena**.
5. In the **Create table with Athena** dialog box, do one of the following:
   - Create a new namespace. Choose **Create a namespace**, and then enter a name in the **Namespace name** field. Namespace names must be 1 to 255 characters and unique within the table bucket. Valid characters are a–z, 0–9, and underscores (_). Underscores aren't allowed at the start of namespace names.
   - Choose **Create namespace**.
   - Specify an existing namespace. Choose **Specify an existing namespace within this table bucket**. Then choose either **Choose from existing namespaces** or **Enter an existing namespace name**. If you have more than 1,000 namespaces in your bucket, you must enter the namespace name if it doesn't appear in the list.
6. Choose **Create table with Athena**.
7. The Amazon Athena console opens and the Athena query editor appears. The **Catalog** field should be populated with **s3tablescatalog/** followed by the name of your table bucket, for example, **s3tablescatalog/*amzn-s3-demo-bucket***. The **Database** field should be populated with the namespace that you created or selected earlier.

   > **Note**
   >
   > If you don't see these values in the **Catalog** and **Database** fields, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see the section called “Integrating S3 Tables with AWS analytics services”.

8. The query editor is populated with a sample query that you can use to create a table. Modify the query to specify the table name and columns that you want your table to have.
9. When you're finished modifying the query, choose **Run** to create your table.

> **Note**
>
> - If you receive the error "Insufficient permissions to execute the query. Principal does not have any privilege on specified resource" when you try to run a query in Athena, you must be granted the necessary Lake Formation permissions on the table. For more information, see the section called “Granting Lake Formation permission on a table or database”.
> - If you receive the error "Iceberg cannot access the requested resource" when you try to run a query in Athena, go to the AWS Lake Formation console and make sure that you've granted yourself permissions on the table bucket catalog and database (namespace) that you created. Don't specify a table when granting these permissions. For more information, see the section called “Granting Lake Formation permission on a table or database”.
> - If you receive the following error message when running a SELECT query in Athena, this message is caused by having capital letters in your table name or your column names in your table definition: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names." Make sure that your table and column names are all lowercase.

If your table creation was successful, the name of your new table appears in the list of tables in Athena. When you navigate back to the Amazon S3 console, your new table appears in the **Tables** list on the bucket details page for your table bucket after you refresh the list.

Using the AWS CLI

This example shows how to create a table with a schema by using the AWS CLI and specifying table metadata with JSON. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3tables create-table --cli-input-json file://mytabledefinition.json
```

For the `mytabledefinition.json` file, use the following example table definition. To create a partitioned table, include a `partitionSpec` in the table metadata. Each partition field references a column in your schema by its `sourceId` and applies a transform (such as `identity`, `bucket`, `truncate`, `year`, `month`, `day`, or `hour`) to produce the partition value. Because partition fields reference schema columns by ID, you must assign an explicit `id` to each field in your schema. The following example assigns IDs to the schema fields and partitions the table by the `registration_date` column using the `day` transform. To use this example, replace the *`user input placeholders`* with your own information.

```
{
    "tableBucketARN": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket",
    "namespace": "your_namespace",
    "name": "example_table",
    "format": "ICEBERG",
    "metadata": {
        "iceberg": {
            "schema": {
                "fields": [
                     {"id": 1, "name": "id", "type": "int", "required": true},
                     {"id": 2, "name": "name", "type": "string"},
                     {"id": 3, "name": "registration_date", "type": "timestamp"}
                ]
            },
            "partitionSpec": {
                "specId": 0,
                "fields": [
                    {"sourceId": 3, "transform": "day", "name": "registration_day"}
                ]
            }
        }
    }
}
```

Using a query engine

You can create a table in a supported query engine that's connected to your table buckets, such as in an Apache Spark session on Amazon EMR.

The following example shows how to create a table with Spark by using `CREATE` statements, and add table data by using `INSERT` statements or by reading data from an existing file. To create a

partitioned table, add a `PARTITIONED BY` clause to the `CREATE` statement. You can partition by one or more columns directly (identity partitioning) or by applying a partition transform such as `bucket`, `truncate`, `years`, `months`, `days`, or `hours`. The following example partitions the table by the `registration_date` column using the `days` transform. To use this example, replace the *`user input placeholders`* with your own information.

```
spark.sql(
" CREATE TABLE IF NOT EXISTS s3tablesbucket.example_namespace.`example_table` (
    id INT,
    name STRING,
    registration_date TIMESTAMP
)
USING iceberg
PARTITIONED BY (days(registration_date)) "
)
```

After you create the table, you can load data into the table. Choose from the following methods:

- Add data into the table by using the `INSERT` statement.

  ```
  spark.sql(
  """
      INSERT INTO s3tablesbucket.my_namespace.my_table
      VALUES
          (1, 'ABC', 100),
          (2, 'XYZ', 200)
  """)
  ```

- Load an existing data file.

  1. Read the data into Spark:

     ```
     val data_file_location = "Path such as S3 URI to data file"
     val data_file = spark.read.parquet(data_file_location)
     ```

  2. Write the data into an Iceberg table:

     ```
     data_file.writeTo("s3tablesbucket.my_namespace.my_table").using("Iceberg").tableProperty
      ("format-version", "2").createOrReplace()
     ```

Migrating tables to S3 Tables

S3 Tables can migrate AWS Glue-registered Apache Hive tables stored as Apache Parquet in Amazon S3 general purpose buckets to managed Apache Iceberg tables in S3 Tables. S3 Tables automatically copy your data to a new table and convert Hive data types to Iceberg types. Small files are combined into larger ones and data is compressed, so your tables are optimized for storage cost and query performance. You don't need to provision or manage any compute, and your source table remains unchanged and fully available for both reads and writes during a migration job. Migration doesn't move your source objects stored in S3 Intelligent-Tiering to the Frequent Access tier or reset their days since last access. You can migrate tables by using the Amazon S3 console, the AWS CLI, the S3 Tables API, or the S3 Tables migration skill.

For more information, see How to migrate a table to S3 Tables.

Features

Optimized destination table

Migration compresses or recompresses your data and compacts small files, so your destination table is optimized for both storage cost and query performance. You can configure the compression codec, target file size, and snapshot management settings, or use the defaults. For more information, see Setting up table migration.

Incremental sync before cutover

You don't need to stop writes to your source table. After the initial migration is complete, you can sync the table to migrate changes from your source table to keep the destination table current, and minimize cutover downtime.

Automatic Hive-to-Iceberg conversion

Migration maps your Hive schema and partitioning to an Iceberg schema and partition spec. You can either specify a destination schema to choose the columns and data types you want or let migration generate a compatible Iceberg schema based on the AWS Glue-registered schema. The migration policy controls how migration handles any data type or schema mismatches, while also automatically performing predefined data type conversions between compatible Hive and Iceberg types. For more information, see Migration policy.

Migration review, reports, and statistics

Migration produces reports and statistics that you can use to review your source table and track progress. Before copying data, the migration job writes compatibility reports that list issues to resolve. By default, the migration job continues automatically after planning. You can choose to pause and review the reports before any data is copied. After the copy, the object migration report shows the result for each source object. You can also check migration statistics at any time to see how a start or sync is progressing. For more information, see Migration reports and statistics.

For more information about table migration, see the following topics.

- How to migrate a table to S3 Tables
  - Data type mappings for table migration
  - Migration reports and statistics
- Setting up table migration
- Running a table migration

How to migrate a table to S3 Tables

S3 Tables migration creates an Apache Iceberg table from an existing AWS Glue Data Catalog Apache Hive table that's stored as Apache Parquet. The migration job validates, transforms, and optimizes your data. Your source data remains available throughout the migration.

When you start a migration, the migration job automatically creates a read-only destination table in S3 Tables, and manages it for the duration of the migration. The table remains read-only until you complete the migration so that a later sync doesn't overwrite your changes. You can delete the destination table at any time.

For more information, see the following topics.

Topics

- Start, Sync, and Complete
- What you can do during a migration
- How data is migrated

Start, Sync, and Complete

You migrate a table in three steps:

1. **Start** – `StartTableMigration` creates a new destination table with the specified table name from the defined source table and copies the source data. You can optionally set additional configurations such as schema, compression codec, and migration policy.
2. **Sync** – `SyncTableMigration` copies only the objects and partitions that changed since the previous start or sync, even if the change is only within part of a partition. Sync is an optional step, and you can sync as many times as you need. You also use sync to resume a failed or cancelled migration.
3. **Complete** – `CompleteTableMigration` enables writes on the destination table in addition to reads, and turns on table maintenance. After you complete a migration, no further migration operations are permitted.

Only one start or sync operation can run on a destination table at a time. If a start or sync fails or is cancelled, see Data from failed or cancelled migrations.

What you can do during a migration

You do not have to alter the workloads running on your source table before or during the migration. You can read, write, and delete objects in your source table. In the destination table, you can query the data and delete the table at any time during the migration. Queries return the data that the migration job has committed so far. Writes, file compaction, and unreferenced file removal are disabled until you complete the migration. Snapshot management remains enabled and uses the snapshot management settings that you specify when you start the migration. Throughout the process, you retain control of the source and destination tables, including the ability to delete them or revoke permissions, though doing so can cause the migration job to fail.

How data is migrated

Each start and sync moves through two states: planning and migrating. `GetTableMigration` reports the current state, such as `planning`, `migrating`, or `succeeded`. To check the current state, call `GetTableMigration`. For a description of every state, see Migration states.

- **Planning state**: The migration job validates your request and identifies every source object in the source table. The outputs of the planning state are a table compatibility report and an object compatibility report, which list any issues that were detected. For more information, see Migration reports. You have the option to review the reports before any data is migrated. To review the reports before any data is copied, set `reviewMigrationPlan` to `true` when you start or sync. The migration then waits in the `pendingReview` state until you approve or cancel it.
- **Migrating state**: If `reviewMigrationPlan` is `false` or once you've approved the migration plan, the migration moves to the migrating state. In this state, the migration job reads each planned object, applies your migration policy, converts data types, recompresses and compacts the data, and commits it to the destination table. Each commit adds an Iceberg snapshot. At the end of the migrating state, the migration job writes an object migration report.

Migration policy

The migration policy determines how migration handles differences between your source data and the destination and governs data conversion rules. You set this in `dataMigration.migrationPolicies` when you call `StartTableMigration`, and subsequent sync operations use the same policy. The migration policy has two settings that control how migration handles mismatches, and cannot be changed once set. Both default to `fail`.

- `unmatchedSourceFieldsPolicy` controls source columns that aren't in the destination schema. Set it to `fail` (default) to fail the source object (the data file holding the unmatched column), which fails the migration, or `drop` to leave out the column.
- `incompatibleValuesPolicy` controls optional (or nullable) columns that can't be converted to their destination data type. Set it to `fail` (default) to fail the migration job, or `setNull` to write the destination column as null instead.

unmatchedSourceFieldsPolicy	incompatibleValuesPolicy	Source column that isn't in the destination	Incompatible column or value
fail (default)	fail (default)	Fails	Fails
fail	setNull	Fails	Written as null
drop	fail	Dropped (not migrated)	Fails
drop	setNull	Dropped (not migrated)	Written as null

A source column is required only if the destination schema marks the matching destination column as required. To specify a schema, see Setting up table migration.

The object migration report lists the objects that failed and the columns that were dropped or written as null. If any object fails, the migration job ends in the `failed` state. Failed jobs will not migrate all the data in the source table. For more information, see Troubleshooting.

Migration policy example

Your AWS Glue table `orders` has the columns `order_id` (`bigint`) and `quantity` (`int`), and you let migration infer the schema.

Orders Tables

Column	AWS Glue data type
order_id	bigint
quantity	int

`file-a.parquet` has an extra column, `audit`. `file-b.parquet` stores `quantity` as `bigint`, which is incompatible with `int`. The mismatch is handled as follows based on your migration policy.

unmatchedSourceFieldsPolicy	incompatibleValuesPolicy	file-a.parquet (extra column)	file-b.parquet (bigint in an int column)
fail	fail	Fails	Fails
fail	setNull	Fails	Migrates, with quantity written as null for this object
drop	fail	Migrates without the audit column	Fails
drop	setNull	Migrates without the audit column	Migrates, with quantity written as null for this object

Partitioning

Migration keeps your source table's partitioning. The migration job copies the objects under each partition location that's registered in AWS Glue, including objects in subdirectories. For an unpartitioned table, migration copies the objects directly under the table location. For partition requirements and limits, see Considerations and limitations.

Data type mappings for table migration

What migration transforms

A migration job applies the following transformations as it copies your data. It doesn't change your source table or its objects.

Transformation	What the migration job does
Data types	Converts each source column data type to an Iceberg-compatible data type.

Transformation	What the migration job does
Column matching	Matches source columns to destination columns by name, ignoring case, at every nesting level. If two source columns match the same destination column, the migration fails during planning.
Partitioning	Represents your Hive partitions as an Iceberg partition spec that uses identity transforms. The migration job writes the partition values into each data file.
File format and compression	Writes Apache Parquet files and recompresses your data.
File size and layout	Combines small files and splits large ones toward a target file size.

Iceberg version support

Migration creates Iceberg format version 2 tables by default. Of the data types that Iceberg version 3 adds, migration supports nanosecond timestamps (`timestamp_ns` and `timestamptz_ns`). Choose version 3 if your source has nanosecond timestamps and every engine that reads the table supports version 3.

How column data types change

Migration identifies the level of fidelity with which it can convert data from the source schema and destination schema. Migration classifies the transformations of columns and values as follows.

- **Lossless** – The data type stays the same and every value is represented exactly.
- **Widened** – The column moves to a larger data type of the same kind, and every value is represented exactly. For example, `int` becomes `long`.
- **Converted** – The column moves to a different data type that keeps every value, but some information about the data type is lost. For example, a `tinyint` column becomes `decimal(5,2)`, which keeps every value but loses the information that the column only ever held whole numbers.
- **Incompatible** – The destination data type can't hold every value of the source type. For example, `bigint` becomes `int`. Your `incompatibleValuesPolicy` determines whether the migration job fails or the column is written as null.

- **Unsupported** – The source data type has no equivalent Iceberg data type, or migration doesn't support the requested data type conversion. The migration fails under every migration policy. Migration checks data types during planning, using the AWS Glue table and a sample data file. To migrate the table, leave the column out of your destination schema and set `unmatchedSourceFieldsPolicy` to `drop`. You can't leave out a partition column.

The table compatibility report lists each column's data type change. For more information on the table compatibility report, see Migration reports and statistics.

Data type mapping for an inferred schema

If you don't specify a destination schema, migration infers one from the AWS Glue table definition, and every column is optional. The following table shows the Iceberg data type for each AWS Glue data type.

AWS Glue data type	Iceberg data type	Data type change
`boolean`	`boolean`	Lossless
`tinyint`, `smallint`	`int`	Widened
`int`	`int`	Lossless
`bigint`	`long`	Lossless
`float`	`float`	Lossless
`double`	`double`	Lossless
`decimal(p,s)`	`decimal(p,s)`	Lossless
`string`	`string`	Lossless
`varchar(n)`	`string`	Widened (the length limit isn't preserved)
`char(n)`	`string`	Converted (the length limit and trailing-space padding aren't kept)

AWS Glue data type	Iceberg data type	Data type change
`binary`	`binary`	Lossless
`date`	`date`	Lossless
`timestamp`	`timestamp` or `timestamp tz` , based on the sample object	Lossless for microseconds. Widened for milliseconds. Converted for INT96. See Timestamps.
`timestamp with local time zone`	`timestamptz`	Lossless
`array<T>`, `map<K,V>`, `struct`	`list<T>`, `map<K,V>`, `struct`	Each nested field is classified on its own.
`uniontype` , `void`, `interval_year_month` , `interval_day_time` , `decimal` with precision above 38	None	Unsupported

Data type changes in a destination schema

If you specify a destination schema, you can request the data type changes in the following table. Changes that narrow a data type (for example, `bigint` to `int`), parse text (for example, `string` to a number), or drop part of a date or timestamp are incompatible and follow your `incompatibleValuesPolicy`. Other changes aren't supported. The same rules apply when a source object stores a different data type than its AWS Glue column.

Source data type	Destination data type	Result
`int`	`long`	Widened
`float`	`double`	Widened
`decimal`	A wider `decimal`	Widened

Source data type	Destination data type	Result
`int`	`double`	Converted
`tinyint`, `smallint`	`float`, `double`	Converted
An integer type	A `decimal` that holds every digit	Converted
`decimal(p,0)`	`int`, `long`, `float`, `double`	Converted, if the digits fit (9 for `int`, 18 for `long`, 7 for `float`, 15 for `double`)
`string`	`binary`	Converted
A number, `boolean`, or `date`	`string`	Converted

Timestamps

An AWS Glue `timestamp` column can store a local date and time (Iceberg `timestamp`) or an instant in UTC (Iceberg `timestamptz`). The migration job reads a sample object to choose the data type, as the following table shows.

How the sample object stores the column	Iceberg data type	Example writers
Parquet `TIMESTAMP` adjusted to UTC (`isAdjustedToUTC` is `true`), or the older `TIMESTAMP_MILLIS` or `TIMESTAMP_MICROS` type	`timestamptz`	Apache Spark with `spark.sql.parquet.outputTimestampType` set to `TIMESTAMP_MICROS` or `TIMESTAMP_MILLIS`
Parquet `TIMESTAMP` not adjusted to UTC (`isAdjustedToUTC` is `false`)	`timestamp`	Apache Spark `TIMESTAMP_NTZ` columns
INT96	`timestamptz`	Apache Hive, and Apache Spark by default

How the sample object stores the column	Iceberg data type	Example writers
The sample object doesn't contain the column (for example, the column was added after the migration job sampled it)	`timestamp`	None

You can't change a column data type between `timestamp` and `timestamptz`, except for a column stored as INT96. If a later source object stores the column differently, that object fails. Migration widens millisecond timestamps to microseconds and drops the digits below a microsecond in INT96 timestamps. Nanosecond timestamps require Iceberg format version 3.

Nested data types

Migration maps `struct`, `array`, and `map` types to Iceberg `struct`, `list`, and `map` types, and classifies each nested field on its own.

Migration reports and statistics

Migration statistics

When you call `GetTableMigration`, the response includes two sets of statistics. Planning statistics describe the source objects that planning scanned and included. Both planning and migration statistics describe a single start or sync. A sync counts the objects that it adds or re-migrates, so an object that several syncs re-migrate is counted in each of them.

Planning statistics

Statistic	Description
`objectsScanned`	The number of source objects that planning scanned under the table location.
`objectsPlanned`	The number of source objects that planning included in the migration.
`partitionCount`	The number of AWS Glue partitions that planning included in the migration.

Migration statistics

Statistic	Description
`objectsMigrated`	The number of source objects that were copied and are available for querying.
`objectsFailedMigration`	The number of source objects that failed to migrate.
`objectsPendingMigration`	The number of planned source objects that are remaining.

Migration reports

A migration job writes the following reports that you can use to review and validate a migration:

- **Table compatibility report** – Written at the end of the planning state, before any data is copied. Lists any issues with your table definition and shows how each column's data type maps to the destination table.
- **Object compatibility report** – Written at the end of the planning state, before any data is copied. Lists every source object that was scanned in planning, whether the object is included in the migration job, and any issue that prevents it from migrating, such as an archived storage class or unsupported encryption.
- **Object migration report** – Written when a start or sync operation completes. Lists every source object that the migration job attempted, whether it migrated, how its data was transformed, and why it failed. This report is not written if the operation fails in the planning state.

If a migration fails, `failureReason` in the `GetTableMigration` response tells you which report to look at. A code of `tableCompatibilityReport`, `objectCompatibilityReport`, or `objectMigrationReport` names the report to review. For every code and how to resolve it, see Troubleshooting. For each compatibility report, `migrationOutput` also returns the number of invalid findings (`invalidFindings`) by category: `access`, `metadata`, `data`, and `internal`. Within a report, the following fields are stable and can be used for automation: states, finding categories, and failure reasons. Conversely, finding subcategories, outcomes, and messages can change or be added over time, making these unsuitable for automation. Values that the migration API returns, such as states, failure reasons, and finding categories, are stable.

Report location and structure

In start and sync operations, you specify the output location of the migration reports using the `migrationOutput` parameter. Specify one general purpose bucket. You can optionally specify a prefix for each report. If a prefix is not specified for a report, all reports are written to the root of the bucket. Under each prefix, migration writes the reports for each start and sync in a folder named for its migration ID, as in the following example:

```
amzn-s3-demo-bucket/
    your-optional-prefix/
        migration-id/
            table-compatibility-report/
            object-compatibility-report/
            object-migration-report/
```

After migration writes a report, `GetTableMigration` returns the report's object key and checksum in `migrationOutput`. For the object compatibility report and the object migration report, the key points to the report's manifest. For the table compatibility report, the key points to the report file. Each start and sync is assigned a unique migration ID to prevent overwriting reports.

Compatibility reports

Table compatibility report

The table compatibility report shows whether your table can be migrated and what happens to each column. The report is a single CSV file with a header row. Each row is one finding and has the following columns:

Column	Description
`finding_type`	Whether the finding prevents the migration, such as `invalid` for an unsupported file format, or is informational, such as for a column whose data type widens.
`finding_category`	The kind of issue: `access` for permissions, `metadata` for your table definition, `data` for values such as partition values, or `internal` for an error in S3 Tables.

Column	Description
finding_subcategory	The check that found an issue, such as glueTableLocation , or a column's data type change, such as schemaTransformation.widened .
details	A JSON object. For an issue, findingDescription explains how to resolve the issue. For a column, details shows the column path, the AWS Glue data type, the data type in the sample object, the destination data type, whether the column is a partition column, the policy that applies, and what happens to the column (outcome).

For example:

finding_type	finding_category	finding_subcategory	details
invalid	metadata	glueTableParameters	{"findingDescription":"one or more unsupported Hive Parameters entries were detected (see details.unsupportedKeys); transactional (ACID) tables ... are not supported; fix the table definition before migrating","violations":["transactional=true"],"unsupportedKeys":["transactional=true"]}
informational	metadata	schemaTransformation.widened	{"findingDescription":"the field migrates from the AWS Glue type to its destination type","fName":"quantity","fId":2,"sourceType":"smallint","sampleFileType":null,"d

finding_type	finding_category	finding_subcategory	details
			estinationType":"int","partitionField":false}
informational	metadata	schemaInference.sample	{"bucket":"amzn-s3-demo-bucket","key":"orders/dt=2026-01-15/part-0.parquet","versionId":"3HL4kqtJlcpXroDTDmJ.rmSpXd3dIbrHY"}

For a column change, `outcome` in `details` shows what happens to the column. The following table shows example values.

outcome	What it means
`migrated`	The column is migrated.
`nullForFile`	The column is written as null in each source object whose values can't be converted, because `incompatibleValuesPolicy` is `setNull`.
`dropped`	The column isn't migrated, because `unmatchedSourceFieldsPolicy` is `drop`.
`fail`	The column prevents the migration.
`excluded`	The migration job leaves the column out under every migration policy, such as an index column that pandas wrote.

Object compatibility report

The object compatibility report's manifest lists the report files and their columns. The report files are CSV files without a header row, with one row for each source object that planning scanned. The number of rows equals `objectsScanned`, and the number of rows for planned objects equals `objectsPlanned`.

The report has the following columns:

Column	Description
`bucket`	The source bucket.
`key`	The object key.
`version_id`	The version ID. Empty for an unversioned object.
`status`	Whether planning included the object in the migration, for example `planned`.
`finding_type`	`invalid` if the issue prevents migration, or `informational` if it doesn't.
`finding_category`	The kind of issue, such as `metadata` for an object property. Empty if the object has no issue.
`finding_subcategory`	The check that found the issue, such as `storageClass` , or the reason that the object isn't in the migration.
`result_message`	A JSON object with the object's size, last modified date, ETag, storage class, encryption type, and AWS KMS key ARN, and a message that describes the issue and how to resolve it.

Object migration report

The object migration report's manifest lists each results file, its checksum, the report schema, and the number of objects that migrated and failed. Each results file is a CSV file without a header row, with one row for each source object that migration attempted.

The report has the following columns:

Column	Description
`bucket`	The source bucket.
`key`	The object key.
`version_id`	The version ID. Empty for an unversioned object.

Column	Description
`status`	Whether the object migrated or failed, for example `migrated`.
`http_status_code`	An HTTP status code for the object, such as `200` for a migrated object, or `500` for a failed object that can succeed if you run another sync.
`error_code`	The error code for a failed object, such as `sourceAccessDenied` or `schemaIncompatible`. Empty for a migrated object.
`result_message`	A JSON message detailing the transformations that migration applied to the object, such as values that were widened or written as null, or columns that were dropped. For a failed object, the message explains why it failed and how to fix it.

Setting up table migration

Before you migrate a table, make sure that you have the required resources and permissions. You can also choose how migration writes your destination table.

Required resources

- **Source table** – An AWS Glue Data Catalog Apache Hive external table that stores its data as Apache Parquet in an Amazon S3 general purpose bucket.
- **Destination table bucket** – The table bucket where the migration job creates the destination table. The namespace must already exist, and the destination table does not.
- **Report bucket** – A general purpose bucket where the migration job writes the compatibility reports and the object migration report.
- **Migration role** – An AWS Identity and Access Management (IAM) role that the migration job assumes to run the migration.

For account, Region, and source table requirements, see Considerations and limitations.

Required permissions

The migration role must be able to read your source and write your destination table and reports. Grant the role the following permissions:

- **Source table metadata** – `glue:GetTable`, `glue:GetPartitions`, and `glue:GetColumnStatisticsForPartition`.
- **Source data** – `s3:ListBucket`, `s3:GetObject`, and `s3:GetObjectVersion` on the source bucket.
- **Destination table** – `s3tables:CreateTable`, `s3tables:GetTable`, `s3tables:GetTableMetadataLocation`, `s3tables:UpdateTableMetadataLocation`, `s3tables:GetTableData`, `s3tables:PutTableData`, and `s3tables:PutTableMaintenanceConfiguration`. To set tags, encryption, or a storage class, also `s3tables:TagResource`, `s3tables:PutTableEncryption`, or `s3tables:PutTableStorageClass`.
- **Reports** – `s3:PutObject` on the report bucket and prefixes.
- **Encryption** – For SSE-KMS source objects, `kms:Decrypt` on the source key. For an SSE-KMS destination table, `kms:GenerateDataKey`, `kms:Decrypt`, and `kms:DescribeKey` on the destination key, which must also allow `maintenance.s3tables.amazonaws.com`. For an SSE-KMS report bucket, `kms:GenerateDataKey` on that key. For an example IAM policy with these AWS KMS permissions, see Permission requirements for S3 Tables SSE-KMS encryption.

The role's trust policy must allow the S3 Tables migration service principal, `migration.s3tables.amazonaws.com`, to assume the role. The following example permissions policy grants the required permissions. The policy includes AWS KMS statements for SSE-KMS source objects, an SSE-KMS destination table, and an SSE-KMS report bucket. To use these examples, remove the statements for keys that you don't use and replace the placeholders with your own information.

      "Condition": {
        "StringLike": {
          "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-
bucket/migration-reports/*"
        }
      }
    }
  ]
}
```

The following example trust policy allows the migration service principal to assume the role only for migrations into the specified table bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "migration.s3tables.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
          "aws:SourceArn": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-
demo-table-bucket"
        }
      }
    }
  ]
}
```

Permissions for the identity that runs the migration

The IAM identity that runs the migration needs the following permissions:

- `s3tables:StartTableMigration` and `s3tables:ListTableMigrations` on the table bucket.
- `s3tables:SyncTableMigration`, `s3tables:GetTableMigration`, `s3tables:UpdateTableMigration`, and `s3tables:CompleteTableMigration` on the destination table.
- `iam:PassRole` on the migration role, with the condition `iam:PassedToService` set to `migration.s3tables.amazonaws.com`.
- If the destination table uses SSE-KMS, `kms:DescribeKey` and `kms:GenerateDataKey` on the table's KMS key. The key must be an enabled customer managed key.

The migration role must be in the same AWS account as the identity that starts the migration.

Destination and migration settings

You set these settings and your migration policy when you start a migration, and every sync uses them. Settings that you don't specify use the defaults in the following table.

Setting	Request parameter	Default	Supported values
Compression codec	`destinationTable.properties.compressionCodec`	`zstd`	`zstd`, `snappy`, `gzip`, `uncompressed`
Dictionary encoding	`destinationTable.properties.dictionaryEncoding`	`true`	`true`, `false`
Target file size	`dataMigration.maintenanceSettings.icebergCompaction.targetFileSizeMB`	512	64–512 MB
Compaction strategy	`dataMigration.maintenanceSettings.icebergCompaction.strategy`	`binpack`	`binpack`. After you complete the migration, you can choose another strategy in the table's maintenance configuration.
Sort order	`destinationTable.icebergSortOrder`	None	Up to five columns. Requires a destination schema that you specify.
Minimum snapshots to keep	`dataMigration.maintenanceSettings.icebergSnapshotManagement.minSnapshotsToKeep`	3	3 or more
Maximum snapshot age	`dataMigration.maintenanceSettings.icebergSnapshotManagement.maxSnapshotAgeHours`	120 hours	1 hour or more
Iceberg version	`destinationTable.properties.icebergFormatVersion`	2	Versions 2 and 3

Considerations and limitations

- Migration supports AWS Glue Data Catalog Apache Hive external tables that store data as Apache Parquet, either uncompressed or compressed with Snappy, gzip, Zstandard, Brotli, or LZ4. Other file formats (e.g. ORC, Avro, and JSON) and compression codecs (e.g. LZO) aren't supported.
- Migration doesn't support transactional (ACID) Hive tables, tables already in an open table format, such as Apache Iceberg, tables that use a storage handler, or tables that skip header or footer lines.
- Migration doesn't support AWS Glue tables that are also registered with AWS Lake Formation.
- A sync fails an object that was overwritten since the previous start or sync, even if the new object has identical content, and even in a versioned bucket.
- The source table, the destination table bucket, and the report bucket must be in the same AWS account and AWS Region. Cross-account and federated AWS Glue catalogs aren't supported.
- Every partition must be stored under the table location registered in AWS Glue. If a partition is stored elsewhere, move its data under the table location and update its location in AWS Glue.
- Partition columns of data type `binary`, `uniontype`, or a nested data type aren't supported. Tables that use Amazon Athena partition projection aren't supported until you register their partitions in AWS Glue, for example with `MSCK REPAIR TABLE`.
- Migration doesn't support source objects encrypted with customer-provided keys (SSE-C).
- Migration doesn't support objects that require a restore before access, such as S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, and the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers. Restore or copy these objects first.
- Migration doesn't copy AWS Glue table parameters, SerDe settings, column statistics, column comments, or the table description. It also doesn't migrate directory markers, empty objects, or objects whose name or folder starts with `_` or `.`, which Hive ignores.
- Migration is available in the US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Mumbai), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm) AWS Regions.

Running a table migration

To migrate a table by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Table buckets**.
3. Choose the name of the destination table bucket.
4. Choose **Create table**, and then choose **Migrate existing table**.
5. For **Source table**, choose the AWS Glue database and the Apache Hive table that you want to migrate.
6. For **Destination table**, choose the namespace and enter a name for the table.
7. For **IAM role**, choose an existing role that has the required permissions, or choose **Create new IAM role**. For the permissions, see Required permissions.
8. For **Report location**, choose the general purpose bucket for the reports. (Optional) Enter a prefix.
9. Choose **Start migration**.

To sync or complete the migration, choose the destination table, and then choose **Sync** or **Complete migration**.

To migrate a table by using the AWS CLI

1. Start the migration. Specify the migration role, the destination table, the source AWS Glue table, and where to write the reports. The migration job creates the destination table in the namespace that you specify.

```
aws s3tables start-table-migration \
    --role-arn arn:aws:iam::111122223333:role/S3TablesMigrationRole \
    --destination-table '{"tableBucketARN":"arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-
bucket","namespace":"example_namespace","name":"example_table"}' \
    --source-type glueTable --source '{"glueTable":
{"catalogId":"111122223333","databaseName":"example_database","tableName":"example_source_t
 \
    --migration-output '{"bucket":"arn:aws:s3:::amzn-s3-demo-
bucket","prefixes":{"tableCompatibilityReport":"migration-
```

```
reports","objectCompatibilityReport":"migration-
reports","objectMigrationReport":"migration-reports"}}'
```

The response returns a `migrationId` that you use to track the migration. You can also set the following options in the start command:

- **Review the compatibility reports before copying data** – Add `--review-migration-plan`, and then approve the migration in step 2.
- **Specify the destination schema** – Add `schema` to `--destination-table`.
- **Choose migration policy** – Add `--data-migration '{"migrationPolicies":{"unmatchedSourceFieldsPolicy":"drop","incompatibleValuesPolicy":"setNull"}}'`. For more information, see Migration policy.
- **Change compression and compaction** – Add `properties` to `--destination-table`, or `maintenanceSettings` to `--data-migration`. For more information, see Destination and migration settings.

2. (Optional) If you started the migration with `--review-migration-plan`, review the compatibility reports, and then approve the migration. To approve it, set the requested state to `queued`.

```
aws s3tables update-table-migration \
    --migration-id example-migration-id \
    --requested-state queued
```

The migration moves to `queued`, and then to `migrating` when the copy begins. To stop the migration instead, set `--requested-state` to `cancelled`. You can approve a migration only in the `pendingReview` state. For what happens when you cancel a table migration, see Data from failed or cancelled migrations.

3. Monitor the migration until it reaches the `succeeded` state.

```
aws s3tables get-table-migration \
    --migration-id example-migration-id
```

The response includes the migration's state, planning and migration statistics, whether it's a start or a sync, and the location of each report after it's written. If the migration fails, the response also includes a `failureReason`. For more information, see Troubleshooting.

4. (Optional) Sync the table to copy source data that changed since the previous start or sync. Specify the migration role, the destination table ARN, and where to write the reports.

```
aws s3tables sync-table-migration \
    --role-arn arn:aws:iam::111122223333:role/S3TablesMigrationRole \
    --table-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket/table/example-table-id \
    --migration-output '{"bucket":"arn:aws:s3:::amzn-s3-demo-bucket","prefixes":{"tableCompatibilityReport":"migration-reports","objectCompatibilityReport":"migration-reports","objectMigrationReport":"migration-reports"}}'
```

   A sync uses the source, migration policy, and settings that you specified when you started the migration. For more information, see Migration policy. Each sync returns a new `migrationId`, which you monitor the same way as a start. To review the compatibility reports before a sync copies data, add `--review-migration-plan`, and then approve the sync as described in step 2.

5. Verify the destination table.

6. Complete the migration.

```
aws s3tables complete-table-migration \
    --table-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket/table/example-table-id
```

   Completing a migration can't be undone. Completing makes the destination table read-write and turns on automatic table maintenance. After you complete the migration, you can query and write to the table with any engine that supports Apache Iceberg.

Monitoring a migration

To track a start or sync, call `GetTableMigration` and check `state` and the planning and migration statistics. For each state, see Migration states. You can also view a migration's state, statistics, and reports in the Amazon S3 console.

Migration states

Each start and sync reports its progress as a state.

State	Description
`new`	S3 Tables accepted the request and are validating the source and destination.
`planning`	The migration job is identifying and checking the source objects, and writing the compatibility reports.
`pendingReview`	Planning is done, and the migration is waiting for you to approve or cancel it. Only when you set `reviewMigrationPlan` to `true`.
`queued`	The migration is approved and waiting to start copying data.
`migrating`	The migration job is copying data into the destination table and committing it.
`succeeded`	Every planned object migrated.
`failed`	The migration stopped because of an error. For the cause, see `failureReason` .
`cancelling`	You cancelled the migration, and it's stopping.
`cancelled`	The migration stopped because you cancelled it.

You can cancel a start or sync in the `new`, `planning`, `pendingReview`, `queued`, or `migrating` state.

Troubleshooting

When a migration fails, `failureReason` in the `GetTableMigration` response includes a code that tells you where to look:

- **A report found issues (`tableCompatibilityReport`, `objectCompatibilityReport`, `objectMigrationReport`)** – Review the report named in the code, and fix the issues that it lists.
- **Permissions or resources (`rolePermissions`, `sourcePermissions`, `destinationPermissions`, `resourceNotFound`, `reportBucketNotSupported`)** – Check the migration role's trust policy and permissions, the bucket and key policies, and the names,

Regions, and requirements of the resources that you specified. The `detail` field names the resource involved.

- **The source can't be migrated (`sourceNotSupported`)** – See Considerations and limitations.
- **Internal error (`internalError`)** – Try again, and contact AWS Support if the error persists.

After you fix the cause, continue as described in Data from failed or cancelled migrations.

Data from failed or cancelled migrations

When a migration fails or is cancelled, the destination table keeps the data that migration already committed. To continue, call `ListTableMigrations` and check `hasValidPlan` for each earlier start or sync:

- If the destination table exists and `hasValidPlan` is `true` for an earlier start or sync, fix the cause of any failure, and then sync the table.
- If the destination table exists but `hasValidPlan` is `false` for every earlier start or sync, fix the cause of the failure, delete the destination table, and then start a new migration.
- If the destination table doesn't exist, start a new migration.

A sync migrates the objects that didn't migrate and any objects that you added, and removes the data of objects that you deleted. You can also delete the destination table at any time. Deleting it deletes the migrated data and ends the migration. To migrate the table again, start a new migration.

Deleting an Amazon S3 table

You can delete a table by using the Amazon S3 REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or by using integrated query engines.

> **Note**
>
> S3 Tables doesn't support the `DROP TABLE` operation with `purge=false`. Some versions of Apache Spark always set this flag to `false` even when running `DROP TABLE PURGE` commands. To delete a table, you can retry `DROP TABLE` with `purge=true`, or use the S3 Tables DeleteTable REST API operation.

Important

When you delete a table, you need to know the following:

- Deleting a table is permanent and cannot be undone. Before deleting a table, make sure that you have backed up or replicated any important data.
- All data and configurations associated with the table are permanently removed.

Using the AWS CLI

This example shows how to delete a table by using the AWS CLI. To use this command, replace the *user input placeholders* with your own information.

```
aws s3tables delete-table \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket \
    --namespace example_namespace --name example_table
```

Using a query engine

You can delete a table in an Apache Spark session connected to your Amazon S3 table buckets.

This example shows how to delete a table by using the `DROP TABLE PURGE` command. To use the command, replace the *user input placeholders* with your own information.

```
spark.sql(
" DROP TABLE [IF EXISTS] s3tablesbucket.example_namespace.example_table PURGE")
```

Viewing details about an Amazon S3 table

You can view the general details of a table in a table bucket, such creation details, format and type, in the console or programmatically. You can view table encryption settings, and maintenance settings programmatically by using the S3 Tables REST API, AWS CLI or AWS SDKs.

Viewing table details

Using the AWS CLI

This example shows how to get details about a table by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table --table-bucket-arn arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-bucket --namespace my-namespace --
name my-table
```

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. Select your table bucket, then select your table.
4. Select the **Properties** tab.
5. (Optional) For information about the permission policy attached to the table, select **Permissions**.

Previewing table data

Using the S3 console

You can preview the data in your table directly from the Amazon S3 console using the following procedure.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that contains the table that you want to query.
4. Select the table you want to preview then, choose **Preview**.

> **Note**
>
> The preview shows the first 10 rows and up to 25 columns of your table. Tables over 50mb cannot be previewed.

Encryption details

For more information about table bucket encryption, see Using server-side encryption with AWS KMS keys (SSE-KMS) in table buckets.

Using the AWS CLI

This example shows how to get details about encryption settings for a table by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-encryption --table-bucket-arn arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-bucket --namespace my-namespace --
name my-table
```

Maintenance details

For information about maintenance settings, see Maintenance for table buckets

Using the AWS CLI

This example shows how to get details about maintenance configuration settings for a table by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3tables get-table-maintenance-configuration --table-bucket-arn
 arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket --
namespace my-namespace --name my-table
```

Managing table policies

You can add, delete, update, and view table policies for tables by using the Amazon S3 console, Amazon S3 REST API, AWS SDK and the AWS CLI. For more information, see the following topics. For more information about supported AWS Identity and Access Management (IAM) actions and condition keys for Amazon S3 Tables, see Access management for S3 Tables. For example table policies, see Resource-based policies for S3 Tables.

Adding a table policy

To add a table policy to a table, you can use the Amazon S3 REST API, AWS SDK and the AWS CLI.

Using the AWS CLI

This example shows how to view the policy attached to a table by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3tables get-table-policy \
```

```
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket1/table/tableID \
    --namespace my-namespace \
    --name my-table
```

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that contains your table, then select your table from that bucket.
4. Choose the **Permissions** tab.
5. Under **Table policy**, Choose **Edit**.
6. In the policy editor, enter your policy JSON.
7. (Optional) Choose **Policy examples** to see sample policies that you can adapt to your needs.
8. After entering your policy, choose **Save changes**.

Viewing a table policy

To view the bucket policy attached to a table, you can use the Amazon S3 REST API, AWS SDK and the AWS CLI.

Using the AWS CLI

This example shows how to view the policy attached to a table by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3tables get-table-policy \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket  \
    --namespace my-namespace \
    --name my-table
```

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Amazon S3**.

3. Choose **Table buckets** and select the table bucket name that contains your table, then select your table from that bucket.
4. Choose the **Permissions** tab.

Deleting a table policy

To delete a policy attached to a table, you can use the Amazon S3 REST API, AWS SDK and the AWS CLI.

Using the AWS CLI

This example shows how to delete a table policy by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3tables delete-table-policy \
    --table-ARN arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-
bucket \
    --namespace your-namespace \
    --name your-table
```

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Table buckets** and select the table bucket name that contains your table, then select your table from that bucket.
4. Choose the **Permissions** tab.
5. Under **Table bucket policy**, choose **Delete**.

Using tags with S3 tables

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 tables. You can tag S3 tables when you create them or manage tags on existing tables. For general information about tags, see Tagging for cost allocation or attribute-based access control (ABAC).

> **Note**
>
> There is no additional charge for using tags on tables beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

Common ways to use tags with tables

Use tags on your S3 tables for:

1. **Cost allocation** – Track storage costs by table tag in AWS Billing and Cost Management. For more information, see Using tags for cost allocation.
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 tables based on their tags. For more information, see Using tags for ABAC.

> **Note**
>
> You can use the same tags for both cost allocation and access control.

ABAC for S3 tables

Amazon S3 tables support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, AWS Identity and Access Management (IAM), and S3 table policies. ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 tables based on the table's tags by using the `s3tables:TableBucketTag/tag-key` condition key or the AWS global condition keys: `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys`.

aws:ResourceTag/key-name

Use this condition key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a table is allowed only if the table has the tag key `Department` with the value `Marketing`.

This condition key applies to table actions performed using the Amazon S3 Console, the AWS Command Line Interface (CLI), S3 APIs, or the AWS SDKs,.

For an example policy, see 1.1 - table policy to restrict operations on the table using tags.

For additional example policies and more information, see Controlling access to AWS resources in the *AWS Identity and Access Management User Guide*.

> **Note**
>
> For actions performed on tables, this condition key acts on the tags applied to the table and not on the tags applied to the table bucket containing the table. Use the `s3tables:TableBucketTag/tag-key` instead if you would like your ABAC policies to act on the tags of the table bucket when performaing table actions.

aws:RequestTag/key-name

Use this condition key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request to tag a table includes the tag key `Department` and that it has the value `Accounting`.

This condition key applies when tag keys are passed in a `TagResource` or `CreateTable` API operation request, or when tagging or creating a table with tags using the Amazon S3 Console, the AWS Command Line Interface (CLI), or the AWS SDKs.

For an example policy, see 1.2 - IAM policy to create or modify tables with specific tags.

For additional example policies and more information, see Controlling access during AWS requests in the *AWS Identity and Access Management User Guide*.

aws:TagKeys

Use this condition key to compare the tag keys in a request with the keys that you specify in the policy to define what tag keys are allowed for access. For example, to allow tagging during the `CreateTable` action, you must create a policy that allows both the `s3tables:TagResource` and `s3tables:CreateTable` actions. You can then use the `aws:TagKeys` condition key to enforce that only specific tags are used in the `CreateTable` request.

This condition key applies when tag keys are passed in a `TagResource`, `UntagResource`, or `CreateTable` API operations or when tagging, untagging, or creating a table with tags using the AWS Command Line Interface (CLI), or the AWS SDKs.

For an example policy, see 1.3 - IAM policy to control the modification of tags on existing resources maintaining tagging governance.

For additional example policies and more information, see Controlling access based on tag keys in the *AWS Identity and Access Management User Guide*.

s3tables:TableBucketTag/tag-key

Use this condition key to grant permissions to specific data in table buckets using tags. This condition key acts, on the most part, on the tags assigned to the table bucket for all S3 tables actions. Even when you create a table with tags, this condition key acts on the tags applied to the table bucket that contains that table. The exceptions are:

- When you create a table bucket with tags, this condition key acts on the tags in the request.

For an example policy, see 1.4 - Using the s3tables:TableBucketTag condition key.

Example ABAC policies for tables

See the following example ABAC policies for Amazon S3 tables.

> **Note**
>
> If you have an IAM or S3 Tables resource-based policy that restricts IAM users and IAM roles based on principal tags, you must attach the same principal tags to the IAM role that Lake Formation uses to access your Amazon S3 data (for example, LakeFormationDataAccessRole) and grant this role the necessary permissions. This is required for your tag-based access control policy to work correctly with your S3 Tables analytics integration.

1.1 - table policy to restrict operations on the table using tags

In this table policy, the specified IAM principals (users and roles) can perform the `GetTable` action only if the value of the table's `project` tag matches the value of the principal's `project` tag.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGetTable",
      "Effect": "Allow",
      "Principal": {
        "AWS": "111122223333"
```

```
      },
      "Action": "s3tables:GetTable",
      "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/my_example_tab;e",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        }
      }
    }
  ]
}
```

1.2 - IAM policy to create or modify tables with specific tags

In this IAM policy, users or roles with this policy can only create S3 tables if they tag the table with the tag key `project` and tag value `Trinity` in the table creation request. They can also add or modify tags on existing S3 tables as long as the `TagResource` request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the tables or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateTableWithTags",
      "Effect": "Allow",
      "Action": [
        "s3tables:CreateTable",
        "s3tables:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": [
            "Trinity"
          ]
        }
      }
    }
  ]
}
```

1.3 - IAM policy to control the modification of tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a table only if the value of the table's `project` tag matches the value of the principal's `project` tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these tables. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your tables.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceTaggingRulesOnModification",
      "Effect": "Allow",
      "Action": [
        "s3tables:TagResource",
        "s3tables:UntagResource"
      ],
      "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket/my_example_table",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "project",
            "environment",
            "owner",
            "cost-center"
          ]
        }
      }
    }
  ]
}
```

1.4 - Using the s3tables:TableBucketTag condition key

In this IAM policy, the condition statement allows access to the table bucket's data only if the table bucket has the tag key `Environment` and tag value `Production`. The

`s3tables:TableBucketTag/<tag-key>` differs from the `aws:ResourceTag/<tag-key>` condition key because, in addition to controlling access to table buckets depending on their tags, it allows you to control access to tables based on the tags on their parent table bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToSpecificTables",
      "Effect": "Allow",
      "Action": "*",
      "Resource": "arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/*",
      "Condition": {
        "StringEquals": {
          "s3tables:TableBucketTag/Environment": "Production"
        }
      }
    }
  ]
}
```

Managing tags for tables

You can add or manage tags for S3 tables using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: TagResource, UntagResource, and ListTagsForResource. For more information, see:

Topics

- Creating tables with tags
- Adding a tag to a table
- Viewing table tags
- Deleting a tag from a table

Creating tables with tags

You can tag Amazon S3 tables when you create them. There is no additional charge for using tags on tables beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging tables, see Using tags with S3 tables.

Permissions

To create a table with tags, you must have the following permissions:

- `s3tables:CreateTable`
- `s3tables:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a table with tags, you can do the following:

- Verify that you have the required Permissions to create the table and apply a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. Your policy may require you to tag your tables with only specific tag keys and values. For more information about ABAC and example table ABAC policies, see ABAC for S3 tables.

Steps

You can create a table with tags applied by using the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and the AWS SDKs.

Using the REST API

For information about the Amazon S3 Tables REST API support for creating a table with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- CreateTable

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a table with tags by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

When you create a table you must provide configuration details. For more information, see Creating an Amazon S3 table. You must also name the table with a name that follows the table naming convention. For more information see Amazon S3 table bucket, table, and namespace naming rules.

Request:

```
aws --region us-west-2 \
s3tables create-table \
--endpoint https://ufwae60e2k.execute-api.us-west-2.amazonaws.com/personal/ \
--table-bucket-arn arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket
--tags '{"Department":"Engineering"}' \
--name my_table_abc \
--namespace my_namesapce_123a \
--format ICEBERG
```

Adding a tag to a table

You can add tags to Amazon S3 tables and modify these tags. For more information about tagging tables, see Using tags with S3 tables.

Permissions

To add a tag to a table, you must have the following permission:

- `s3tables:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a table, you can do the following:

- Verify that you have the required Permissions to add a tag to a table.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.
- The tag key is required. Also, make sure that the tag key and the tag value do not exceed the maximum character length and do not contain restricted characters. For more information, see Tagging for cost allocation or attribute-based access control (ABAC).

Steps

You can add tags to tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and AWS SDKs.

Using the S3 console

To add tags to a table using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the table name.
5. Choose the **Properties** tab.
6. Scroll to the **Tags** section and choose **Add new Tag**.
7. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
8. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
9. You can also edit the values of existing tags on this page.
10. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a table, see the following section in the *Amazon Simple Storage Service API Reference*:

- TagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a table by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws --region us-west-2 \
s3tables tag-resource \
--resource-arn arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-
bucket/table/my_example_table \
```

```
--tags '{"Department":"engineering"}'
```

Viewing table tags

You can view or list tags applied to Amazon S3 tables. For more information about tags, see Using tags with S3 tables.

Permissions

To view tags applied to a table, you must have the following permission:

- `s3tables:ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a table, you can do the following:

- Verify that you have the required Permissions to view or list the tags of the table.

Steps

You can view tags applied to tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a table using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the Table bucket name.
4. Choose the table name within the Table bucket.
5. Choose the **Properties** tab.
6. Scroll to the **Tags** section to view all of the tags applied to the table.
7. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your table by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a table, see the following section in the *Amazon Simple Storage Service API Reference*:

- ListTagsforResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a table. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws --region us-west-2 \
s3tables list-tags-for-resource \
--resource-arn arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/table/my_example_table
```

Deleting a tag from a table

You can remove tags from Amazon S3 tables. For more information about tagging tables, see Using tags with S3 tables.

> **Note**
>
> If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the table.

Permissions

To delete a tag from a table, you must have the following permission:

- `s3tables:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a table, you can do the following:

- Verify that you have the required Permissions to delete a tag from a table.

Steps

You can delete tags from tables by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 Tables REST API, and AWS SDKs.

Using the S3 console

To delete tags from a table using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. Choose the table bucket name.
4. Choose the table name.
5. Choose the **Properties** tab.
6. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
7. Choose **Delete**.
8. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
9. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a table, see the following section in the *Amazon Simple Storage Service API Reference*:

- UnTagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a table by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws --region us-west-2 \
s3tables untag-resource \
--resource-arn arn:aws::s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/table/my_example_table \
--tag-keys '["department"]'
```

Accessing table data

There are multiple ways to access tables in Amazon S3 table buckets. You can integrate tables with AWS analytics services using AWS Glue Data Catalog, or access tables directly using the Amazon S3 Tables Iceberg REST endpoint or the Amazon S3 Tables Catalog for Apache Iceberg. The access method you use will depend on your catalog setup, governance model, and access control needs. The following is an overview of these access methods.

AWS Glue Data Catalog integration

This is the recommended access method for working with tables in S3 table buckets. This integration gives you a unified view of your data estate across multiple AWS analytics services through the AWS Glue Data Catalog. After integration, you can query tables using services such as Athena and Amazon Redshift. Access to tables is managed using IAM permissions. To access tables using this integration, the IAM identity you use needs access to your S3 Tables resources and actions, AWS Glue Data Catalog objects, and the query engine you're using. For more information, see Access management for S3 Tables.

Direct access

Use this method if you need to work with AWS Partner Network (APN) catalog implementations, custom catalog implementations, or if you only need to perform basic read/write operations on tables within a single table bucket. Access to tables is managed using IAM permissions. To access tables, the IAM identity you use needs access to your table resources and S3 Tables actions. For more information, see Access management for S3 Tables.

Accessing tables through the AWS Glue Data Catalog integration

You can integrate S3 table buckets with AWS Glue Data Catalog to access tables from AWS analytics services, such as Amazon Athena, Amazon Redshift, and Quick. The integration populates

the AWS Glue Data Catalog with your table resources, and federates access to those resources. For more information on integrating, see Integrating Amazon S3 Tables with AWS analytics services.

The following AWS analytics services can access tables through this integration:

- Amazon Athena
- Amazon Redshift
- Amazon EMR
- Quick
- Amazon Data Firehose
- AWS Glue ETL
- Querying S3 Tables with SageMaker Unified Studio

Accessing tables using the AWS Glue Iceberg REST endpoint

Once your S3 table buckets are integrated with AWS Glue Data Catalog, you can also use the AWS Glue Iceberg REST endpoint to connect to S3 tables from third-party query engines that support Iceberg. For more information, see Accessing Amazon S3 tables using the AWS Glue Iceberg REST endpoint.

We recommend using the AWS Glue Iceberg REST endpoint when you want to access tables from Spark, PyIceberg, or other Iceberg-compatible clients.

The following clients can access tables directly through the AWS Glue Iceberg REST endpoint:

- Any Iceberg client, including Spark, PyIceberg, and more.

Accessing tables directly

You can access tables directly from open source query engines through methods that bridge S3 Tables management operations to your Apache Iceberg analytics applications. There are two direct access methods: the Amazon S3 Tables Iceberg REST endpoint or the Amazon S3 Tables Catalog for Apache Iceberg. The REST endpoint is recommended.

We recommend direct access if you access tables in self-managed catalog implementations, or only need to perform basic read/write operations on tables in a single table bucket. For other access scenarios, we recommend the AWS Glue Data Catalog integration.

Direct access to tables is managed through either IAM identity-based policies or resource-based policies attached to tables and table buckets.

Accessing tables through the Amazon S3 Tables Iceberg REST endpoint

You can use the Amazon S3 Tables Iceberg REST endpoint to access your tables directly from any Iceberg REST compatible clients through HTTP endpoints, for more information, see Accessing tables using the Amazon S3 Tables Iceberg REST endpoint.

The following AWS analytics services and query engines can access tables directly using the Amazon S3 Tables Iceberg REST endpoint:

Supported query engines

- Any Iceberg client, including Spark, PyIceberg, and more.
- Amazon EMR
- AWS Glue ETL

Accessing tables directly through the Amazon S3 Tables Catalog for Apache Iceberg

You can also access tables directly from query engines like Apache Spark by using the S3 Tables client catalog, for more information, see Accessing Amazon S3 tables with the Amazon S3 Tables Catalog for Apache Iceberg. However, S3 recommends using the Amazon S3 Tables Iceberg REST endpoint for direct access because it supports more applications, without requiring language or engine-specific code.

The following query engines can access tables directly using the client catalog:

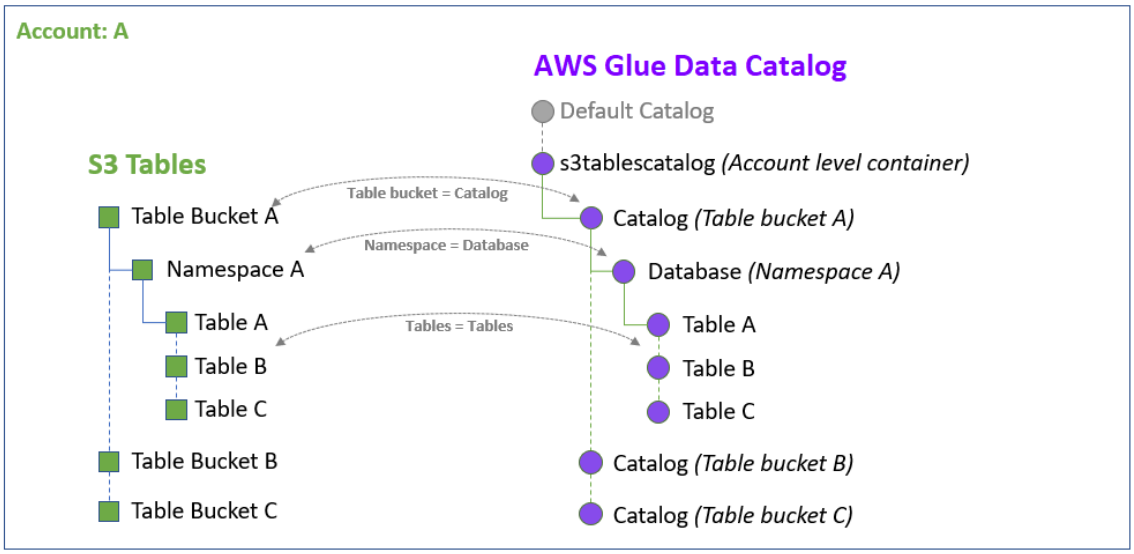
- Apache Spark

Amazon S3 Tables integration with AWS analytics services overview

To make tables in your account accessible by AWS analytics services, you integrate your Amazon S3 table buckets with AWS Glue Data Catalog. This integration allows AWS analytics services to automatically discover and access your table data. You can use this integration to work with your tables in these services:

- Amazon Athena
- Amazon Redshift
- Amazon EMR
- Quick
- Amazon Data Firehose

> **Note**
>
> This integration uses AWS Glue and AWS Lake Formation services and might incur AWS Glue request and storage costs. For more information, see AWS Glue Pricing. Additional pricing applies for running queries on your S3 tables. For more information, see pricing information for the query engine that you're using.



How the integration works

When you integrate S3 Tables with the AWS analytics services, Amazon S3 adds the catalog named `s3tablescatalog` to the AWS Glue Data Catalog in the current Region. Adding the `s3tablescatalog` allows all your table buckets, namespaces, and tables to be populated in the Data Catalog.

> **Note**
>
> These actions are automated through the Amazon S3 console. If you perform this integration programmatically, you must manually take these actions.

You integrate your table buckets once per AWS Region. After the integration is completed, all current and future table buckets, namespaces, and tables are added to the AWS Glue Data Catalog in that Region.

The following illustration shows how the `s3tablescatalog` catalog automatically populates table buckets, namespaces, and tables in the current Region as corresponding objects in the Data Catalog. Table buckets are populated as subcatalogs. Namespaces within a table bucket are populated as databases within their respective subcatalogs. Tables are populated as tables in their respective databases.

After integrating with Data Catalog, you can create Apache Iceberg tables in table buckets and access them through AWS analytics engines such as Amazon Athena, Amazon EMR, as well as third-party analytics engines.

How permissions work

We recommend integrating your table buckets with AWS analytics services so that you can work with your table data across services that use the AWS Glue Data Catalog as a metadata store. Once the integration is enabled, you can use AWS Identity and Access Management (IAM) permissions to grant access to S3 Tables resources and their associated Data Catalog objects.

Make sure that you follow the steps in Integrating S3 Tables with AWS analytics services so that you have the appropriate permissions to access the AWS Glue Data Catalog and your table resources, and to work with AWS analytics services.

Regions supported

S3 Tables integration with AWS analytics services uses AWS Glue Data Catalog with IAM-based access controls in the following regions. In all other regions, the integration also requires AWS Lake Formation.

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Taipei)
- Asia Pacific (Tokyo)
- Asia Pacific (Seoul)
- Asia Pacific (Osaka)
- Asia Pacific (Mumbai)
- Asia Pacific (Hyderabad)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Malaysia)
- Asia Pacific (New Zealand)
- Asia Pacific (Thailand)
- Canada (Central)
- Canada West (Calgary)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Stockholm)
- Europe (Milan)
- Europe (Spain)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Israel (Tel Aviv)
- Mexico (Central)
- South America (São Paulo)

Next steps

- Integrating S3 Tables with AWS analytics services
- Create a namespace
- Create a table

Integrating Amazon S3 Tables with AWS analytics services

This topic covers the prerequisites and procedures needed to integrate your Amazon S3 table buckets with AWS analytics services. For an overview of how the integration works, see S3 Tables integration overview.

> **Note**
>
> This integration uses the AWS Glue Data Catalog and might incur AWS Glue request and storage costs. For more information, see AWS Glue Pricing.
> Additional pricing applies for running queries on S3 Tables. For more information, see pricing information for the query engine that you're using.

Prerequisites for integration

The following prerequisites are required to integrate table buckets with AWS analytics services:

- Create a table bucket.
- Add the following AWS Glue permissions to your AWS Identity and Access Management (IAM) principal:
  - `glue:CreateCatalog` which is required to create `s3tablescatalog` federated catalog in the Data Catalog
  - `glue:PassConnection` grants the calling principal the right to delegate `aws:s3tables` connection creation to Amazon S3 service.
- Update to the latest version of the AWS Command Line Interface (AWS CLI).

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.
If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Integrating table buckets with AWS analytics services

You can integrate table buckets with Data Catalog and AWS analytics services using IAM access controls by default, or optionally use Lake Formation access controls.

When you integrate using IAM access controls, you require IAM privileges to access Amazon S3 table buckets and tables, Data Catalog objects, and the query engine you're using. If you choose to integrate using Lake Formation, then both IAM access controls and Lake Formation grants determine the access to Data Catalog resources. Please refer to *AWS Lake Formation Developer Guide* to learn more about Lake Formation integration.

The following sections describe how you could use Amazon S3 management console or AWS CLI to configure the integration with IAM access controls.

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. Choose **Create table bucket**.

   The **Create table bucket** page opens.
4. Enter a **Table bucket name** and make sure that the **Enable integration** checkbox is selected.
5. Choose **Create table bucket**. Amazon S3 will attempt to automatically integrate your table buckets in that Region.

Using the AWS CLI

To integrate table buckets with IAM access controls using the AWS CLI

The following steps show how to use the AWS CLI to integrate table buckets. To use these steps, replace the *user input placeholders* with your own information.

1. Create a table bucket.

```
aws s3tables create-table-bucket \
--region us-east-1 \
--name amzn-s3-demo-table-bucket
```

2. Create a file called `catalog.json` that contains the following catalog:

```
{
   "Name": "s3tablescatalog",
   "CatalogInput": {
      "FederatedCatalog": {
          "Identifier": "arn:aws:s3tables:us-east-1:111122223333:bucket/*",
          "ConnectionName": "aws:s3tables"
       },
       "CreateDatabaseDefaultPermissions":[
       {
                "Principal": {
                    "DataLakePrincipalIdentifier": "IAM_ALLOWED_PRINCIPALS"
                },
                "Permissions": ["ALL"]
            }
       ],
       "CreateTableDefaultPermissions":[
       {
                "Principal": {
                    "DataLakePrincipalIdentifier": "IAM_ALLOWED_PRINCIPALS"
                },
                "Permissions": ["ALL"]
            }
       ],
       "AllowFullTableExternalDataAccess": "True"
   }
}
```

Create the `s3tablescatalog` catalog by using the following command. Creating this catalog populates the AWS Glue Data Catalog with objects corresponding to table buckets, namespaces, and tables.

```
aws glue create-catalog \
--region us-east-1 \
--cli-input-json file://catalog.json
```

3. Verify that the `s3tablescatalog` catalog was added in AWS Glue by using the following command:

```
aws glue get-catalog --catalog-id s3tablescatalog
```

Migrating to the updated integration process

The AWS analytics services integration process has been updated to use IAM permissions by default. If you've already set up the integration, you can continue to use your current integration. However, if you want to change your existing integration to use IAM permissions instead, see *AWS Lake Formation Developer Guide*. You can also redo the integration to delete your existing setup in AWS Glue Data Catalog and AWS Lake Formation and re-run the integration. This will remove all existing Lake Formation grants and associated access permissions to the `s3tablescatalog`.

1. Open the AWS Lake Formation console at https://console.aws.amazon.com/lakeformation/, and sign in as a data lake administrator. For more information about how to create a data lake administrator, see Create a data lake administrator in the *AWS Lake Formation Developer Guide*.
2. Delete your `s3tablescatalog` catalog by doing the following:
   - In the left navigation pane, choose **Catalogs**.
   - Select the option button next to the `s3tablescatalog` catalog in the **Catalogs** list. On the **Actions** menu, choose **Delete**.
3. Deregister the data location for the `s3tablescatalog` catalog by doing the following:
   - In the left navigation pane, go to the **Administration** section, and choose **Data lake locations**.
   - Select the option button next to the `s3tablescatalog` data lake location, for example, `s3://tables:region:account-id:bucket/*`.

- On the **Actions** menu, choose **Remove**.
- In the confirmation dialog box that appears, choose **Remove**.

4. Now that you've deleted your `s3tablescatalog` catalog and data lake location, you can follow the steps to integrate your table buckets with AWS analytics services by using the updated integration process.

> **Note**
>
> If you want to work with SSE-KMS encrypted tables in integrated AWS analytics services, the role you use needs to have permission to use your AWS KMS key for encryption operations. For more information, see Granting IAM principals permissions to work with encrypted tables in integrated AWS analytics services.

Next steps

- Create a namespace.
- Create a table.

Accessing Amazon S3 tables using the AWS Glue Iceberg REST endpoint

Once your S3 table buckets are integrated with the AWS Glue Data Catalog you can use the AWS Glue Iceberg REST endpoint to connect to your S3 tables from Apache Iceberg-compatible clients, such as PyIceberg or Spark. The AWS Glue Iceberg REST endpoint implements the Iceberg REST Catalog Open API specification which provides a standardized interface for interacting with Iceberg tables. To access S3 tables using the endpoint you need to configure permissions through a combination of IAM policies and AWS Lake Formation grants. The following sections explain how to set up access, including creating the necessary IAM role, defining the required policies, and establishing Lake Formation permissions for both database and table-level access.

For an end to end walkthrough using PyIceberg, see Access data in Amazon S3 Tables using PyIceberg through the AWS Glue Iceberg REST endpoint.

Prerequisites

- Integrate your table buckets with AWS analytics services
- Create a table namespace

- Have access to a data lake administrator account

Authentication methods

The AWS Glue Iceberg REST endpoint supports two authentication methods for reaching your Amazon S3 tables:

- **AWS Signature Version 4 (SigV4)** – The default for AWS SDKs and AWS native analytics engines. See AWS Signature Version 4 for API requests.
- **OAuth 2.0 bearer token** – For external integration partners and third-party query engines that authenticate with an OAuth access token obtained from AWS Sign-In. See Authentication in Connecting to the Data Catalog using AWS Glue Iceberg REST endpoint, and Configure OAuth access to AWS Glue Iceberg REST Catalog in the *AWS Sign-In User Guide*.

Create an IAM role for your client

To access tables through AWS Glue endpoints, you need to create an IAM role with permissions to AWS Glue and Lake Formation actions. This procedure explains how to create this role and configure its permissions.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create a policy**, and choose **JSON** in policy editor.
4. Add the following inline policy that grants permissions to access AWS Glue and Lake Formation actions:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "glue:GetCatalog",
                "glue:GetDatabase",
                "glue:GetDatabases",
```

```
                "glue:GetTable",
                "glue:GetTables",
                "glue:CreateTable",
                "glue:UpdateTable"
            ],
            "Resource": [
                "arn:aws:glue:us-east-1:111122223333:catalog",
                "arn:aws:glue:us-east-1:111122223333:catalog/
s3tablescatalog",
                "arn:aws:glue:us-east-1:111122223333:catalog/s3tablescatalog/
amzn-s3-demo-table-bucket",
                "arn:aws:glue:us-east-1:111122223333:table/s3tablescatalog/
amzn-s3-demo-table-bucket/<namespace>/*",
                "arn:aws:glue:us-east-1:111122223333:database/
s3tablescatalog/amzn-s3-demo-table-bucket/<namespace>"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "lakeformation:GetDataAccess"
            ],
            "Resource": "*"
        }
    ]
}
```

5. After you create the policy, create an IAM role and choose **Custom trust policy** as the **Trusted entity type**.
6. Enter the following for the **Custom trust policy**.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/Admin_role"
            },
            "Action": "sts:AssumeRole",
```

```
            "Condition": {}
        }
    ]
}
```

Define access in Lake Formation

Lake Formation provides fine-grained access control for your data lake tables. When you integrated your S3 bucket with the AWS Glue Data Catalog, your tables were automatically registered as resources in Lake Formation. To access these tables, you must grant specific Lake Formation permissions to your IAM identity, in addition to its IAM policy permissions.

The following steps explain how to apply Lake Formation access controls to allow your Iceberg client to connect to your tables. You must sign in as a data lake administrator to apply these permissions.

Allow external engines to access table data

In Lake Formation, you must enable full table access for external engines to access data. This allows third-party applications to get temporary credentials from Lake Formation when using an IAM role that has full permissions on the requested table.

1. Open the Lake Formation console at https://console.aws.amazon.com/lakeformation/, and sign in as a data lake administrator.
2. In the navigation pane under **Administration**, choose **Application integration settings**.
3. Select **Allow external engines to access data in Amazon S3 locations with full table access**. Then choose **Save**.

Grant Lake Formation permissions on your table resources

Next, grant Lake Formation permissions to the IAM role you created for your Iceberg-compatible client. These permissions will allow the role to create and manage tables in your namespace. You need to provide both database and table-level permissions. For more information, see Granting Lake Formation permission on a table or database.

Set up your environment to use the endpoint

After you have setup the IAM role with the permissions required for table access you can use it to run Iceberg clients from your local machine by configuring the AWS CLI with your role, using the following command:

```
aws sts assume-role --role-arn "arn:aws:iam::<accountid>:role/<glue-irc-role>" --role-session-name <glue-irc-role>
```

To access tables through the AWS Glue REST endpoint, you need to initialize a catalog in your Iceberg-compatible client. This initialization requires specifying custom properties, including sigv4 properties, the endpoint URI and the warehouse location. Specify these properties as follows:

- Sigv4 properties - Sigv4 must be enabled, the signing name is `glue`
- Warehouse location - This is your table bucket, specified in this format: *<accountid>*:s3tablescatalog/*<table-bucket-name>*
- Endpoint URI - Refer to the AWS Glue service endpoints reference guide for the region-specific endpoint

The following example shows how to initialize a pyIceberg catalog.

```
rest_catalog = load_catalog(
        s3tablescatalog,
**{
"type": "rest",
"warehouse": "<accountid>:s3tablescatalog/<table-bucket-name>",
"uri": "https://glue.<region>.amazonaws.com/iceberg",
"rest.sigv4-enabled": "true",
"rest.signing-name": "glue",
"rest.signing-region": region
        }
)
```

For additional information about the AWS Glue Iceberg REST endpoint implementation, see Connecting to the Data Catalog using AWS Glue Iceberg REST endpoint in the *AWS Glue User Guide*.

Accessing Amazon S3 tables with an OAuth 2.0 bearer token

External integration partners and third-party query engines can access your Amazon S3 tables using an OAuth 2.0 bearer token instead of SigV4. The client obtains a short-lived, Glue-scoped access token from AWS Sign-In through a token exchange defined in RFC 8693 on the IETF Datatracker website, then presents it to the AWS Glue Iceberg REST endpoint. AWS Glue validates the token and enforces the same Lake Formation permissions described earlier.

Before a client can use this method, complete the identity-federation setup (IAM OIDC identity provider, an IAM role with a web-identity trust policy, and Lake Formation grants). The partner exchanges an end user's JSON Web Token (JWT) for the access token. For the full setup and token exchange details, see Configure OAuth access to AWS Glue Iceberg REST Catalog in the *AWS Sign-In User Guide*.

> **Note**
>
> When a query engine authenticates with an OAuth bearer token, the Lake Formation permissions are enforced on the IAM role that the customer configured for the integration. Grant that role only the permissions the partner's users should have, for example, SELECT and DESCRIBE on specific tables. See Step 3: Grant Lake Formation permissions to the role in the *AWS Sign-In User Guide* (Configure OAuth access to AWS Glue Iceberg REST Catalog).

Accessing tables using the Amazon S3 Tables Iceberg REST endpoint

You can connect your Iceberg REST client to the Amazon S3 Tables Iceberg REST endpoint and make REST API calls to create, update, or query tables in S3 table buckets. The endpoint implements a set of standardized Iceberg REST APIs specified in the Apache Iceberg REST Catalog Open API specification . The endpoint works by translating Iceberg REST API operations into corresponding S3 Tables operations.

> **Note**
>
> Amazon S3 Tables Iceberg REST endpoint can be used to access tables in AWS Partner Network (APN) catalog implementations or custom catalog implementations. It can also be used if you only need basic read/write access to a single table bucket. For other access scenarios we recommend using the AWS Glue Iceberg REST endpoint to connect to tables, which provides unified table management, centralized governance, and fine-grained access

control. For more information, see Accessing Amazon S3 tables using the AWS Glue Iceberg REST endpoint

Configuring the endpoint

You connect to the Amazon S3 Tables Iceberg REST endpoint using the service endpoint. S3 Tables Iceberg REST endpoints have the following format:

```
https://s3tables.<REGION>.amazonaws.com/iceberg
```

Refer to S3 Tables AWS Regions and endpoints for the Region-specific endpoints.

Catalog configuration properties

When using an Iceberg client to connect an analytics engine to the service endpoint, you must specify the following configuration properties when you initialize the catalog. Replace the *placeholder values* with the information for your Region and table bucket.

- The region-specific endpoint as the endpoint URI: `https://s3tables.<REGION>.amazonaws.com/iceberg`
- Your table bucket ARN as the warehouse location: `arn:aws:s3tables:<region>:<accountID>:bucket/<bucketname>`
- Sigv4 properties for authentication. The SigV4 signing name for the service endpoint requests is: `s3tables`

The following examples show you how to configure different clients to use the Amazon S3 Tables Iceberg REST endpoint.

PyIceberg

To use the Amazon S3 Tables Iceberg REST endpoint with PyIceberg, specify the following application configuration properties:

```
rest_catalog = load_catalog(
  catalog_name,
  **{
    "type": "rest",
```

```
    "warehouse":"arn:aws:s3tables:<Region>:<accountID>:bucket/<bucketname>",
    "uri": "https://s3tables.<Region>.amazonaws.com/iceberg",
    "rest.sigv4-enabled": "true",
    "rest.signing-name": "s3tables",
    "rest.signing-region": "<Region>"
  }
)
```

Apache Spark

To use the Amazon S3 Tables Iceberg REST endpoint with Spark, specify the following application configuration properties, replacing the *placeholder values* with the information for your Region and table bucket.

```
spark-shell \
  --packages "org.apache.iceberg:iceberg-spark-
runtime-3.5_2.12:1.4.1,software.amazon.awssdk:bundle:2.20.160,software.amazon.awssdk:url-
connection-client:2.20.160" \
  --master "local[*]" \
  --conf
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions"
 \
  --conf "spark.sql.defaultCatalog=spark_catalog" \
   --conf "spark.sql.catalog.spark_catalog=org.apache.iceberg.spark.SparkCatalog" \
  --conf "spark.sql.catalog.spark_catalog.type=rest" \
  --conf "spark.sql.catalog.spark_catalog.uri=https://
s3tables.<Region>.amazonaws.com/iceberg" \
  --conf
 "spark.sql.catalog.spark_catalog.warehouse=arn:aws:s3tables:<Region>:<accountID>:bucket/
<bucketname>" \
  --conf "spark.sql.catalog.spark_catalog.rest.sigv4-enabled=true" \
  --conf "spark.sql.catalog.spark_catalog.rest.signing-name=s3tables" \
  --conf "spark.sql.catalog.spark_catalog.rest.signing-region=<Region>" \
  --conf "spark.sql.catalog.spark_catalog.io-
impl=org.apache.iceberg.aws.s3.S3FileIO" \
  --conf
 "spark.hadoop.fs.s3a.aws.credentials.provider=org.apache.hadoop.fs.s3a.SimpleAWSCredentialP
 \
  --conf "spark.sql.catalog.spark_catalog.rest-metrics-reporting-enabled=false"
```

Authenticating and authorizing access to the endpoint

API requests to the S3 Tables service endpoints are authenticated using AWS Signature Version 4 (SigV4). See AWS Signature Version 4 for API requests to learn more about AWS SigV4.

The SigV4 signing name for Amazon S3 Tables Iceberg REST endpoint requests is: `s3tables`

Requests to the Amazon S3 Tables Iceberg REST endpoint are authorized using `s3tables` IAM actions corresponding to the REST API operations. These permissions can be defined in either IAM identity-based policies or resource-based policies attached to tables and table buckets. For more information, see Access management for S3 Tables.

You can track requests made to your tables through the REST endpoint with AWS CloudTrail. Requests will be logged as their corresponding S3 IAM action. For example, a `LoadTable` API will generate a management event for the `GetTableMetadataLocation` operation and a data event for the `GetTableData` operation. For more information, see Logging with AWS CloudTrail for S3 Tables.

Prefix and path parameters

Iceberg REST catalog APIs have a free-form prefix in their request URLs. For example, the `ListNamespaces` API call uses the `GET/v1/{prefix}/namespaces` URL format. For S3 Tables the REST path `{prefix}` is always your url-encoded table bucket ARN.

For example, for the following table bucket ARN: `arn:aws:s3tables:`*`us-east-1`*`:111122223333:bucket/`*`bucketname`* the prefix would be: `arn%3Aaws%3As3tables%3A`*`us-east-1`*`%3A`*`111122223333`*`%3Abucket%2F`*`bucketname`*

Namespace path parameter

Namespaces in an Iceberg REST catalog API path can have multiple levels. However, S3 Tables only supports single-level namespaces. To access a namespace in a multi-level catalog hierarchy, you can connect to a multi-level catalog above the namespace when referencing the namespace. This allows any query engine that supports the 3-part notation of `catalog.namespace.table` to access objects in S3 Tables' catalog hierarchy without compatibility issues compared to using the multi-level namespace.

Supported Iceberg REST API operations

The following table contains the supported Iceberg REST APIs and how they correspond to S3 Tables actions.

Iceberg REST operation	REST path	S3 Tables IAM action	CloudTrail EventName
getConfig	GET /v1/config	s3tables:GetTableBucket	s3tables:GetTableBucket
listNamespaces	GET /v1/{prefix}/namespaces	s3tables:ListNamespaces	s3tables:ListNamespaces
createNamespace	POST /v1/{prefix}/namespaces	s3tables:CreateNamespace	s3tables:CreateNamespace
loadNamespaceMetadata	GET /v1/{prefix}/namespaces/{namespace}	s3tables:GetNamespace	s3tables:GetNamespace
dropNamespace	DELETE /v1/{prefix}/namespaces/{namespace}	s3tables:DeleteNamespace	s3tables:DeleteNamespace
listTables	GET /v1/{prefix}/namespaces/{namespace}/tables	s3tables:ListTables	s3tables:ListTables
createTable	POST /v1/{prefix}/namespaces/{namespace}/tables	s3tables:CreateTable ,s3tables:PutTableData	s3tables:CreateTable ,s3tables:PutObject
loadTable	GET /v1/{prefix}/namespaces/{na	s3tables:GetTableMetadataLo	s3tables:GetTableMetadataLo

Iceberg REST operation	REST path	S3 Tables IAM action	CloudTrail EventName
	mespace}/tables/{table}	cation , s3tables:GetTableData	cation , s3tables:GetObject
updateTable	POST /v1/{prefix}/namespaces/{namespace}/tables/{table}	s3tables:UpdateTableMetadataLocation ,s3tables:PutTableData ,s3tables:GetTableData	s3tables:UpdateTableMetadataLocation ,s3tables:PutObject ,s3tables:GetObject
dropTable	DELETE /v1/{prefix}/namespaces/{namespace}/tables/{table}	s3tables:DeleteTable	s3tables:DeleteTable
renameTable	POST /v1/{prefix}/tables/rename	s3tables:RenameTable	s3tables:RenameTable
tableExists	HEAD /v1/{prefix}/namespaces/{namespace}/tables/{table}	s3tables:GetTable	s3tables:GetTable
namespaceExists	HEAD /v1/{prefix}/namespaces/{namespace}	s3tables:GetNamespace	s3tables:GetNamespace

Considerations and limitations

Following are considerations and limitations when using the Amazon S3 Tables Iceberg REST endpoint.

Considerations

- **CreateTable API behavior** – The `stage-create` option is not supported for this operation, and results in a `400 Bad Request` error. This means you cannot create a table from query results using `CREATE TABLE AS SELECT` (CTAS).
- **DeleteTable API behavior** – You can only drop tables with purge enabled. Dropping tables with `purge=false` is not supported and results in a `400 Bad Request` error. Some versions of Spark always set this flag to false even when running `DROP TABLE PURGE` commands. You can try with `DROP TABLE PURGE` or use the S3 Tables DeleteTable operation to delete a table.
- The endpoint only supports standard table metadata operations. For table maintenance, such as snapshot management and compaction, use S3 Tables maintenance API operations. For more information, see S3 Tables maintenance.

Limitations

- Multilevel namespaces are not supported.
- OAuth-based authentication is not supported.
- Only the `owner` property is supported for namespaces.
- View-related APIs defined in the Apache Iceberg REST Open API specification are not supported.
- Running operations on a table with a `metadata.json` file over 50MB is not supported, and will return a `400 Bad Request` error. To control the size of your `metadata.json` files use table maintenance operations. For more information, see S3 Tables maintenance.

Accessing Amazon S3 tables with the Amazon S3 Tables Catalog for Apache Iceberg

You can access S3 tables from open source query engines like Apache Spark by using the Amazon S3 Tables Catalog for Apache Iceberg client catalog. Amazon S3 Tables Catalog for Apache Iceberg is an open source library hosted by AWS Labs. It works by translating Apache Iceberg operations in your query engines (such as table discovery, metadata updates, and adding or removing tables) into S3 Tables API operations.

Amazon S3 Tables Catalog for Apache Iceberg is distributed as a Maven JAR called `s3-tables-catalog-for-iceberg.jar`. You can build the client catalog JAR from the AWS Labs GitHub repository or download it from Maven. When connecting to tables, the client catalog JAR is used as a dependency when you initialize a Spark session for Apache Iceberg.

Using the Amazon S3 Tables Catalog for Apache Iceberg with Apache Spark

You can use the Amazon S3 Tables Catalog for Apache Iceberg client catalog to connect to tables from open-source applications when you initialize a Spark session. In your session configuration you specify Iceberg and Amazon S3 dependencies, and create a custom catalog that uses your table bucket as the metadata warehouse.

Prerequisites

- An IAM identity with access to your table bucket and S3 Tables actions. For more information, see Access management for S3 Tables.

To initialize a Spark session using the Amazon S3 Tables Catalog for Apache Iceberg

- Initialize Spark using the following command. To use the command, replace the replace the Amazon S3 Tables Catalog for Apache Iceberg *`version number`* with the latest version from AWS Labs GitHub repository, and the *`table bucket ARN`* with your own table bucket ARN.

```
spark-shell \
--packages org.apache.iceberg:iceberg-spark-
runtime-3.5_2.12:1.6.1,software.amazon.s3tables:s3-tables-catalog-for-iceberg-
runtime:0.1.4 \
--conf spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tablesbucket.catalog-
impl=software.amazon.s3tables.iceberg.S3TablesCatalog \
--conf spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-bucket \
--conf
 spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
```

Querying S3 tables with Spark SQL

Using Spark, you can run DQL, DML, and DDL operations on S3 tables. When you query tables you use the fully qualified table name, including the session catalog name following this pattern:

CatalogName.*NamespaceName*.*TableName*

The following example queries show some ways you can interact with S3 tables. To use these example queries in your query engine, replace the *user input placeholder* values with your own.

To query tables with Spark

- Create a namespace

```
spark.sql(" CREATE NAMESPACE IF NOT EXISTS s3tablesbucket.my_namespace")
```

- Create a table

```
spark.sql(" CREATE TABLE IF NOT EXISTS s3tablesbucket.my_namespace.`my_table`
( id INT, name STRING, value INT ) USING iceberg ")
```

- Query a table

```
spark.sql(" SELECT * FROM s3tablesbucket.my_namespace.`my_table` ").show()
```

- Insert data into a table

```
spark.sql(
"""
    INSERT INTO s3tablesbucket.my_namespace.my_table
    VALUES
        (1, 'ABC', 100),
        (2, 'XYZ', 200)
""")
```

- Load an existing data file into a table

1. Read the data into Spark.

```
val data_file_location = "Path such as S3 URI to data file"
val data_file = spark.read.parquet(data_file_location)
```

2. Write the data into an Iceberg table.

```
data_file.writeTo("s3tablesbucket.my_namespace.my_table").using("Iceberg").tableProperty
 ("format-version", "2").createOrReplace()
```

Querying Amazon S3 tables with Athena

Amazon Athena is an interactive query service that you can use to analyze data directly in Amazon S3 by using standard SQL. For more information, see What is Amazon Athena? in the *Amazon Athena User Guide*.

After you integrate your table buckets with AWS analytics services, you can run Data Definition Language (DDL), Data Manipulation Language (DML), and Data Query Language (DQL) queries on S3 tables by using Athena. For more information about how to query tables in a table bucket, see Register S3 Table bucket catalogs in the *Amazon Athena User Guide*.

You can also run queries in Athena from the Amazon S3 console.

Important

When creating tables, make sure that you use all lowercase letters in your table names and table definitions. For example, make sure that your column names are all lowercase. If your table name or table definition contains capital letters, the table isn't supported by AWS Lake Formation or the AWS Glue Data Catalog. In this case, your table won't be visible to AWS analytics services such as Amazon Athena, even if your table buckets are integrated with AWS analytics services.

If your table definition contains capital letters, you receive the following error message when running a SELECT query in Athena: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names."

Using the S3 console and Amazon Athena

The following procedure uses the Amazon S3 console to access the Athena query editor so that you can query a table with Amazon Athena.

Note

Before performing the following steps, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see the section called "Integrating S3 Tables with AWS analytics services".

To query a table

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that contains the table that you want to query.
4. On the bucket details page, choose the option button next to the name of the table that you want to query.
5. Choose **Query table with Athena**.
6. The Amazon Athena console opens and the Athena query editor appears with a sample SELECT query loaded for you. Modify this query as needed for your use case.

   In the query editor, the **Catalog** field should be populated with **s3tablescatalog/** followed by the name of your table bucket, for example, **s3tablescatalog/*amzn-s3-demo-bucket***. The **Database** field should be populated with the namespace where your table is stored.

   > **Note**
   >
   > If you don't see these values in the **Catalog** and **Database** fields, make sure that you've integrated your table buckets with AWS analytics services in this Region. For more information, see the section called "Integrating S3 Tables with AWS analytics services".

7. To run the query, choose **Run**.

   > **Note**
   >
   > - If you receive the error "Insufficient permissions to execute the query. Principal does not have any privilege on specified resource" when you try to run a query in Athena, you must be granted the necessary Lake Formation permissions on the table. For more information, see the section called "Granting Lake Formation permission on a table or database".
   > - If you receive the error "Iceberg cannot access the requested resource" when you try to run the query, go to the AWS Lake Formation console and make sure that you've granted yourself permissions on the table bucket catalog and database (namespace) that you created. Don't specify a table when granting these permissions. For more

information, see the section called “Granting Lake Formation permission on a table or database”.

- If you receive the following error message when running a SELECT query in Athena, this message is caused by having capital letters in your table name or your column names in your table definition: "GENERIC_INTERNAL_ERROR: Get table request failed: com.amazonaws.services.glue.model.ValidationException: Unsupported Federation Resource - Invalid table or column names." Make sure that your table and column names are all lowercase.

Accessing Amazon S3 tables with Amazon Redshift

Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools. Redshift Serverless lets you access and analyze data without all of the configurations of a provisioned data warehouse. For more information, see Get started with serverless data warehouses in the *Amazon Redshift Getting Started Guide*.

Query Amazon S3 tables with Amazon Redshift

Prerequisites

- Integrate your table buckets with AWS analytics services.
  - Create a namespace.
  - Create a table.
- Managing access to a table or database with Lake Formation.

After you complete the prerequisites, you can begin using Amazon Redshift to query tables in one of the following ways:

- Using the Amazon Redshift query editor v2
- Connecting to an Amazon Redshift data warehouse using SQL client tools
- Using the Amazon Redshift Data API

Accessing Amazon S3 tables with Amazon EMR

Amazon EMR (previously called Amazon Elastic MapReduce) is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data. Using these frameworks and related open-source projects, you can process data for analytics purposes and business intelligence workloads. Amazon EMR also lets you transform and move large amounts of data into and out of other AWS data stores and databases.

You can use Apache Iceberg clusters in Amazon EMR to work with S3 tables by connecting to table buckets in a Spark session. To connect to table buckets in Amazon EMR, you can use the AWS analytics services integration through AWS Glue Data Catalog, or you can use the open source Amazon S3 Tables Catalog for Apache Iceberg client catalog.

> **Note**
>
> S3 Tables is supported on Amazon EMR version 7.5 or higher.

Connecting to S3 table buckets with Spark on an Amazon EMR Iceberg cluster

In this procedure, you set up an Amazon EMR cluster configured for Apache Iceberg and then launch a Spark session that connects to your table buckets. You can set this up using the AWS analytics services integration through AWS Glue, or you can use the open source Amazon S3 Tables Catalog for Apache Iceberg client catalog. For information about the client catalog, see Accessing tables using the Amazon S3 Tables Iceberg REST endpoint.

Choose your method of using tables with Amazon EMR from the following options.

Amazon S3 Tables Catalog for Apache Iceberg

The following prerequisites are required to query tables with Spark on Amazon EMR using the Amazon S3 Tables Catalog for Apache Iceberg.

For the latest version of the client catalog JAR, see the s3-tables-catalog GitHub repository.

Prerequisites

- Attach the `AmazonS3TablesFullAccess` policy to the IAM role you use for Amazon EMR.

> **Note**
>
> Apache Iceberg V3 requires Amazon EMR release 7.12 or later. The variant data type requires Amazon EMR release 8.0 or later. The geometry, geography, unknown, and nanosecond-precision timestamp data types require Amazon EMR release 8.1 or later.

To set up an Amazon EMR cluster to query tables with Spark

1. Create a cluster with the following configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws emr create-cluster --release-label emr-7.12.0 \
--applications Name=Spark \
--configurations file://configurations.json \
--region us-east-1 \
--name My_Spark_Iceberg_Cluster \
--log-uri s3://amzn-s3-demo-bucket/ \
--instance-type m5.xlarge \
--instance-count 2 \
--service-role EMR_DefaultRole \
--ec2-attributes \

InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef0,KeyName=my-key-pair
```

   `configurations.json`:

```
[{
"Classification":"iceberg-defaults",
"Properties":{"iceberg.enabled":"true"}
}]
```

2. Connect to the Spark primary node using SSH.
3. To initialize a Spark session for Iceberg that connects to your table bucket, enter the following command. Replace the *user input placeholders* with your table bucket ARN.

```
spark-shell \
```

```
--packages software.amazon.s3tables:s3-tables-catalog-for-iceberg-runtime:0.1.8
 \
--conf spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tablesbucket.catalog-
impl=software.amazon.s3tables.iceberg.S3TablesCatalog \
--conf spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-bucket1 \
--conf spark.sql.defaultCatalog=s3tablesbucket \
--conf
 spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
```

4. Query your tables with Spark SQL. For example queries, see the section called “Querying S3 tables with Spark SQL”.

AWS analytics services integration

The following prerequisites are required to query tables with Spark on Amazon EMR using the AWS analytics services integration.

Prerequisites

- Integrate your table buckets with AWS analytics services.
- Create the default service role for Amazon EMR (`EMR_DefaultRole_V2`). For details, see Service role for Amazon EMR (EMR role) .
- Create the Amazon EC2 instance profile for Amazon EMR (`EMR_EC2_DefaultRole`). For details, see Service role for cluster EC2 instances (EC2 instance profile).
  - Attach the `AmazonS3TablesFullAccess` policy to `EMR_EC2_DefaultRole`.

To set up an Amazon EMR cluster to query tables with Spark

1. Create a cluster with the following configuration. To use this example, replace the *`user input placeholder`* values with your own information.

> **Note**
>
> Apache Iceberg V3 requires Amazon EMR release 7.12 or later. The variant data type requires Amazon EMR release 8.0 or later. The geometry, geography, unknown, and

nanosecond-precision timestamp data types require Amazon EMR release 8.1 or later.

```
aws emr create-cluster --release-label emr-7.12.0 \
--applications Name=Spark \
--configurations file://configurations.json \
--region us-east-1 \
--name My_Spark_Iceberg_Cluster \
--log-uri s3://amzn-s3-demo-bucket/ \
--instance-type m5.xlarge \
--instance-count 2 \
--service-role EMR_DefaultRole \
--ec2-attributes \

InstanceProfile=EMR_EC2_DefaultRole,SubnetId=subnet-1234567890abcdef0,KeyName=my-key-pair
```

`configurations.json`:

```
[{
"Classification":"iceberg-defaults",
"Properties":{"iceberg.enabled":"true"}
}]
```

2. Connect to the Spark primary node using SSH.
3. Enter the following command to initialize a Spark session for Iceberg that connects to your tables. Replace the *user input placeholders* for Region, account ID and table bucket name with your own information.

```
spark-shell \
--conf
 spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
 \
--conf spark.sql.defaultCatalog=s3tables \
--conf spark.sql.catalog.s3tables=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tables.catalog-
impl=org.apache.iceberg.aws.glue.GlueCatalog \
--conf spark.sql.catalog.s3tables.client.region=us-east-1 \
```

```
--conf spark.sql.catalog.s3tables.glue.id=111122223333:s3tablescatalog/amzn-s3-demo-table-bucket
```

4. Query your tables with Spark SQL. For example queries, see the section called "Querying S3 tables with Spark SQL"

Note

If you are using the `DROP TABLE PURGE` command with Amazon EMR:

- Amazon EMR version 7.5

  Set the Spark config `spark.sql.catalog.your-catalog-name.cache-enabled` to `false`. If this config is set to `true`, run the command in a new session or application so the table cache is not activated.

- Amazon EMR versions higher than 7.5

  `DROP TABLE` is not supported. You can use the S3 Tables `DeleteTable` REST API to delete a table.

Visualizing table data with Quick

Quick is a fast business analytics service to build visualizations, perform ad hoc analysis, and quickly get business insights from your data. Quick seamlessly discovers AWS data sources, enables organizations to scale to hundreds of thousands of users, and delivers fast and responsive query performance by using the Quick Super-fast, Parallel, In-Memory, Calculation Engine (SPICE). For more information, see What is Quick? in the *Quick user guide*.

After you Integrate your table buckets with AWS analytics services, you can create data sets from your tables and work with them in Quick using SPICE or direct SQL queries from your query engine. Quick supports Athena as a data source for S3 tables.

Configure permissions for Quick to access tables

Before working with S3 table data in Quick you must grant permissions to the Quick service role and the Quick admin user permissions on the tables you want to access. Additionally, if you use AWS Lake Formation, you also need to grant Lake Formation permissions to your Quick admin user on those tables you want to access.

Grant permissions to the Quick service role

When set up Quick for the first time in your account, AWS creates a service role that allows Quick to access data sources in other AWS services, such as Athena or Amazon Redshift. The default role name is `aws-quicksight-service-role-v0`.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** and select the Quick service role. The default name is `aws-quicksight-service-role-v0`
3. Choose **Add permissions** and then **Create inline policy**.
4. Select **JSON** to open the JSON policy editor, then add the following policy.

   JSON

   ```
   {
     "Version":"2012-10-17",
     "Statement": [
       {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "glue:GetCatalog",
         "Resource": "*"
       }
     ]
   }
   ```

5. Choose **Next**, enter a **Policy name** and then **Create policy**.

To configure Lake Formation permissions for the Quick admin user

1. Run the following AWS CLI command to find the ARN of your Quick admin user.

   ```
   aws quicksight list-users --aws-account-id 111122223333 --namespace default --
   region region
   ```

2. Grant Lake Formation permissions to this ARN. For details, see Managing access to a table or database with Lake Formation.

Using table data in Quick

You can connect to table data using Athena as a data source.

Prerequisites

- Integrate your table buckets with AWS analytics services.
  - Create a namespace.
  - Create a table.
  - Configure permissions for Quick to access tables.
- Sign up for Quick.

1. Sign in to your Quick account at https://quicksight.aws.amazon.com/
2. In the dashboard, choose **New analysis**.
3. Choose **New dataset**.
4. Select **Athena**.
5. Enter a **Data source name**, then choose **Create data source**.
6. Choose Use custom SQL. You will not be able to select your table from the **Choose your table** pane.
7. Enter an Athena SQL query that captures the columns you want to visualize, then choose **Confirm query**. For example, use the following query to select all columns:

```
SELECT * FROM "s3tablescatalog/table-bucket-name".namespace.table-name
```

8. Choose **Visualize** to analyze data and start building dashboards. For more information, see Visualizing data in Quick and Exploring interactive dashboards in Quick

Streaming data to tables with Amazon Data Firehose

Amazon Data Firehose is a fully managed service for delivering real-time streaming data to destinations such as Amazon S3, Amazon Redshift, Amazon OpenSearch Service, Splunk, Apache Iceberg tables, and custom HTTP endpoints or HTTP endpoints owned by supported third-party service providers. With Amazon Data Firehose, you don't need to write applications or manage resources. You configure your data producers to send data to Firehose, and it automatically delivers the data to the destination that you specified. You can also configure Firehose to transform your

data before delivering it. To learn more about Amazon Data Firehose, see What is Amazon Data Firehose?

Complete these steps to set up Firehose streaming to tables in S3 table buckets:

1. Integrate your table buckets with AWS analytics services.
2. Configure Firehose to deliver data into your S3 tables. To do so, you create an AWS Identity and Access Management (IAM) service role that allows Firehose to access your tables.
3. Grant the Firehose service role explicit permissions to your table or table's namespace. For more information, see Grant necessary permissions.
4. Create a Firehose stream that routes data to your table.

Creating a role for Firehose to use S3 tables as a destination

Firehose needs an IAM service role with specific permissions to access AWS Glue tables and write data to S3 tables. You need this provide this IAM role when you create a Firehose stream.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Policies**
3. Choose **Create a policy**, and choose **JSON** in policy editor.
4. Add the following inline policy that grants permissions to all databases and tables in your data catalog. If you want, you can give permissions only to specific tables and databases. To use this policy, replace the *`user input placeholders`* with your own information.

   JSON

```
{

```

```
        }
    ]
}
```

This policy has a statements that allow access to Kinesis Data Streams, invoking Lambda functions and access to AWS KMS keys. If you don't use any of these resources, you can remove the respective statements.

If error logging is enabled, Firehose also sends data delivery errors to your CloudWatch log group and streams. For this, you must configure log group and log stream names. For log group and log stream names, see Monitor Amazon Data Firehose Using CloudWatch Logs.

5. After you create the policy, create an IAM role with **AWS service** as the **Trusted entity type**.
6. For **Service or use case**, choose **Kinesis**. For **Use case** choose **Kinesis Firehose**.
7. Choose **Next**, and then select the policy you created earlier.
8. Give your role a name. Review your role details, and choose **Create role**. The role will have the following trust policy.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole"
            ],
            "Principal": {
                "Service": [
                    "firehose.amazonaws.com"
                ]
            }
        }
    ]
}
```

Creating a Firehose stream to S3 tables

The following procedure shows how to create a Firehose stream to deliver data to S3 tables using the console. The following prerequisites are required to set up a Firehose stream to S3 tables.

Prerequisites

- Integrate your table buckets with AWS analytics services.
  - Create a namespace.
  - Create a table.
- Create the Role for Firehose to access S3 Tables.
- Grant necessary permissions to the Firehose service role you created to access tables.

To provide routing information to Firehose when you configure a stream, you use your namespace as the database name and the name of a table in that namespace. You can use these values in the Unique key section of a Firehose stream configuration to route data to a single table. You can also use this values to route to a table using JSON Query expressions. For more information, see Route incoming records to a single Iceberg table.

To set up a Firehose stream to S3 tables (Console)

1. Open the Firehose console at https://console.aws.amazon.com/firehose/.
2. Choose **Create Firehose stream**.
3. For **Source**, choose one of the following sources:
   - Amazon Kinesis Data Streams
   - Amazon MSK
   - Direct PUT
4. For **Destination**, choose **Apache Iceberg Tables**.
5. Enter a **Firehose stream name**.
6. Configure your **Source settings**.
7. For **Destination settings**, choose **Current account** to stream to tables in your account or **Cross-account** for tables in another account.
   - For tables in the **Current account**, select your S3 Tables catalog from the **Catalog** dropdown.

- For tables in a **Cross-account**, enter the **Catalog ARN** of the catalog you want to stream to in another account.

8. Configure database and table names using **Unique Key configuration**, JSONQuery expressions, or in a Lambda function. For more information, refer to Route incoming records to a single Iceberg table and Route incoming records to different Iceberg tables in the *Amazon Data Firehose Developer Guide*.
9. Under **Backup settings**, specify a **S3 backup bucket**.
10. For **Existing IAM roles** under **Advanced settings**, select the IAM role you created for Firehose.
11. Choose **Create Firehose stream**.

For more information about the other settings that you can configure for a stream, see Set up the Firehose stream in the *Amazon Data Firehose Developer Guide*.

Running ETL jobs on Amazon S3 tables with AWS Glue

AWS Glue is a serverless data integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use AWS Glue jobs to run extract, transform, and load (ETL) pipelines to load data into your data lakes. For more information about AWS Glue, see What is AWS Glue? in the *AWS Glue Developer Guide*.

An AWS Glue job encapsulates a script that connects to your source data, processes it, and then writes it out to your data target. Typically, a job runs extract, transform, and load (ETL) scripts. Jobs can run scripts designed for Apache Spark runtime environments. You can monitor job runs to understand runtime metrics such as completion status, duration, and start time.

You can use AWS Glue jobs to process data in your S3 tables by connecting to your tables through the integration with AWS analytics services, or, connect directly using the Amazon S3 Tables Iceberg REST endpoint or the Amazon S3 Tables Catalog for Apache Iceberg. This guide covers the basic steps to get started using AWS Glue with S3 Tables, including:

Topics

- Step 1 – Prerequisites
- Step 2 – Create a script to connect to table buckets
- Step 3 – Create a AWS Glue job that queries tables

Choose your access method based on your specific AWS Glue ETL job requirements:

- **AWS analytics services integration (Recommended)** – Recommended when you need centralized metadata management across multiple AWS analytics services, need to leverage existing AWS Glue Data Catalog permissions and optionally Lake Formation, or are building production ETL pipelines that integrate with other AWS services like Athena or Amazon EMR.
- **Amazon S3 Tables Iceberg REST endpoint** – Recommended when you need to connect to S3 tables from third-party query engines that support Apache Iceberg, build custom ETL applications that need direct REST API access, or when you require control over catalog operations without dependencies on AWS Glue Data Catalog.
- **Amazon S3 Tables Catalog for Apache Iceberg** – Use only for legacy applications or specific programmatic scenarios that require the Java client library. This method is not recommended for new AWS Glue ETL job implementations due to additional `JAR` dependency management and complexity.

> **Note**
>
> S3 Tables is supported on AWS Glue version 5.0 or higher. Apache Iceberg V3 requires AWS Glue version 5.1 or higher, and the V3 data types require AWS Glue version 6.0 or higher.

Step 1 – Prerequisites

Before you can query tables from a AWS Glue job you must configure an IAM role that AWS Glue can use to run the job. Choose your method of access to see specific prerequisites for that method.

AWS analytics services integration (Recommended)

Prerequisites required to use the S3 Tables AWS analytics integration to run AWS Glue jobs.

- Integrate your table buckets with AWS analytics services.
- Create an IAM role for AWS Glue.
  - Attach the `AmazonS3TablesFullAccess` managed policy to the role.
  - Attach the `AmazonS3FullAccess` managed policy to the role.

Amazon S3 Tables Iceberg REST endpoint

Prerequisites to use the Amazon S3 Tables Iceberg REST endpoint to run AWS Glue ETL jobs.

- Create an IAM role for AWS Glue.
  - Attach the `AmazonS3TablesFullAccess` managed policy to the role.
  - Attach the `AmazonS3FullAccess` managed policy to the role.

Amazon S3 Tables Catalog for Apache Iceberg

Prerequisites use the Amazon S3 Tables Catalog for Apache Iceberg to run AWS Glue ETL jobs.

- Create an IAM role for AWS Glue.
  - Attach the `AmazonS3TablesFullAccess` managed policy to the role.
  - Attach the `AmazonS3FullAccess` managed policy to the role.
  - To use the Amazon S3 Tables Catalog for Apache Iceberg you need to download the client catalog JAR and upload it to an S3 bucket.

    Downloading the catalog JAR

    1. Check for the latest version on Maven Central. You can download the JAR from Maven central using your browser, or using the following command. Make sure to replace the *`version number`* with the latest version.

       ```
       wget https://repo1.maven.org/maven2/software/amazon/s3tables/s3-tables-catalog-for-iceberg-runtime/0.1.5/s3-tables-catalog-for-iceberg-runtime-0.1.5.jar
       ```

    2. Upload the downloaded JAR to an S3 bucket that your AWS Glue IAM role can access. You can use the following AWS CLI command to upload the JAR. Make sure to replace the *`version number`* with the latest version, and the *`bucket name`* and *`path`* with your own.

       ```
       aws s3 cp s3-tables-catalog-for-iceberg-runtime-0.1.5.jar s3://amzn-s3-demo-bucket/jars/
       ```

Step 2 – Create a script to connect to table buckets

To access your table data when you run an AWS Glue ETL job, you configure a Spark session for Apache Iceberg that connects to your S3 table bucket. You can modify an existing script to connect

to your table bucket or create a new script. For more information on creating AWS Glue scripts, see Tutorial: Writing an AWS Glue for Spark script in the *AWS Glue Developer Guide*.

You can configure the session to connect to your table buckets through the any of the following S3 Tables access methods:

- S3 Tables AWS analytics services integration (Recommended)
- Amazon S3 Tables Iceberg REST endpoint
- Amazon S3 Tables Catalog for Apache Iceberg

Choose from the following access methods to view setup instructions and configuration examples.

AWS analytics services integration (Recommended)

As a prerequisites to query tables with Spark on AWS Glue using the AWS analytics services integration, you must Integrate your table buckets with AWS analytics services

You can configure the connection to your table bucket through a Spark session in a job or with AWS Glue Studio magics in an interactive session. To use the following examples, replace the *placeholder values* with the information for your own table bucket.

Using a PySpark script

Use the following code snippet in a PySpark script to configure a AWS Glue job to connect to your table bucket using the integration.

```
spark = SparkSession.builder.appName("SparkIcebergSQL") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog","s3tables") \
    .config("spark.sql.catalog.s3tables",
 "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tables.catalog-impl",
 "org.apache.iceberg.aws.glue.GlueCatalog") \
    .config("spark.sql.catalog.s3tables.glue.id",
 "111122223333:s3tablescatalog/amzn-s3-demo-table-bucket") \
    .config("spark.sql.catalog.s3tables.warehouse", "s3://amzn-s3-demo-table-
bucket/warehouse/") \
```

```
    .getOrCreate()
```

Using an interactive AWS Glue session

If you are using an interactive notebook session with AWS Glue 5.0, specify the same configurations using the `%%configure` magic in a cell prior to code execution.

```
%%configure
{"conf":
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
 --conf spark.sql.defaultCatalog=s3tables --conf
 spark.sql.catalog.s3tables=org.apache.iceberg.spark.SparkCatalog --conf
 spark.sql.catalog.s3tables.catalog-impl=org.apache.iceberg.aws.glue.GlueCatalog
 --conf spark.sql.catalog.s3tables.glue.id=111122223333:s3tablescatalog/amzn-s3-
demo-table-bucket --conf spark.sql.catalog.s3tables.warehouse=s3://amzn-s3-demo-
table-bucket/warehouse/"}
```

Amazon S3 Tables Iceberg REST endpoint

You can configure the connection to your table bucket through a Spark session in a job or with AWS Glue Studio magics in an interactive session. To use the following examples, replace the *placeholder values* with the information for your own table bucket.

Using a PySpark script

Use the following code snippet in a PySpark script to configure a AWS Glue job to connect to your table bucket using the endpoint.

```
spark = SparkSession.builder.appName("glue-s3-tables-rest") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog", "s3_rest_catalog") \
    .config("spark.sql.catalog.s3_rest_catalog",
 "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3_rest_catalog.type", "rest") \
    .config("spark.sql.catalog.s3_rest_catalog.uri", "https://
s3tables.Region.amazonaws.com/iceberg") \
    .config("spark.sql.catalog.s3_rest_catalog.warehouse",
 "arn:aws:s3tables:Region:111122223333:bucket/amzn-s3-demo-table-bucket") \
```

```
    .config("spark.sql.catalog.s3_rest_catalog.rest.sigv4-enabled", "true") \
    .config("spark.sql.catalog.s3_rest_catalog.rest.signing-name", "s3tables") \
    .config("spark.sql.catalog.s3_rest_catalog.rest.signing-region", "Region") \
    .config('spark.sql.catalog.s3_rest_catalog.io-
impl','org.apache.iceberg.aws.s3.S3FileIO') \
    .config('spark.sql.catalog.s3_rest_catalog.rest-metrics-reporting-
enabled','false') \
    .getOrCreate()
```

Using an interactive AWS Glue session

If you are using an interactive notebook session with AWS Glue 5.0, specify the same configurations using the `%%configure` magic in a cell prior to code execution. Replace the placeholder values with the information for your own table bucket.

```
%%configure
{"conf":
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
 --conf spark.sql.defaultCatalog=s3_rest_catalog --conf
 spark.sql.catalog.s3_rest_catalog=org.apache.iceberg.spark.SparkCatalog
 --conf spark.sql.catalog.s3_rest_catalog.type=rest --conf
 spark.sql.catalog.s3_rest_catalog.uri=https://s3tables.Region.amazonaws.com/
iceberg --conf
 spark.sql.catalog.s3_rest_catalog.warehouse=arn:aws:s3tables:Region:111122223333:bucket/
amzn-s3-demo-table-bucket --conf spark.sql.catalog.s3_rest_catalog.rest.sigv4-
enabled=true --conf spark.sql.catalog.s3_rest_catalog.rest.signing-name=s3tables
 --conf spark.sql.catalog.s3_rest_catalog.rest.signing-region=Region --conf
 spark.sql.catalog.s3_rest_catalog.io-impl=org.apache.iceberg.aws.s3.S3FileIO --
conf spark.sql.catalog.s3_rest_catalog.rest-metrics-reporting-enabled=false"}
```

Amazon S3 Tables Catalog for Apache Iceberg

As a prerequisite to connecting to tables using the Amazon S3 Tables Catalog for Apache Iceberg you must first download the latest catalog jar and upload it to an S3 bucket. Then, when you create your job, you add the the path to the client catalog JAR as a special parameter. For more information on job parameters in AWS Glue, see Special parameters used in AWS Glue jobs in the *AWS Glue Developer Guide*.

You can configure the connection to your table bucket through a Spark session in a job or with AWS Glue Studio magics in an interactive session. To use the following examples, replace the *`placeholder values`* with the information for your own table bucket.

Using a PySpark script

Use the following code snippet in a PySpark script to configure a AWS Glue job to connect to your table bucket using the JAR. Replace the placeholder values with the information for your own table bucket.

```
spark = SparkSession.builder.appName("glue-s3-tables") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog", "s3tablesbucket") \
    .config("spark.sql.catalog.s3tablesbucket",
 "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tablesbucket.catalog-impl",
 "software.amazon.s3tables.iceberg.S3TablesCatalog") \
    .config("spark.sql.catalog.s3tablesbucket.warehouse",
 "arn:aws:s3tables:Region:111122223333:bucket/amzn-s3-demo-table-bucket") \
    .getOrCreate()
```

Using an interactive AWS Glue session

If you are using an interactive notebook session with AWS Glue 5.0, specify the same configurations using the `%%configure` magic in a cell prior to code execution. Replace the placeholder values with the information for your own table bucket.

```
%%configure
{"conf":
 "spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
 --conf spark.sql.defaultCatalog=s3tablesbucket --conf
 spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog
 --conf spark.sql.catalog.s3tablesbucket.catalog-
impl=software.amazon.s3tables.iceberg.S3TablesCatalog --conf
 spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:Region:111122223333:bucket/
amzn-s3-demo-table-bucket", "extra-jars": "s3://amzn-s3-demo-bucket/jars/s3-
tables-catalog-for-iceberg-runtime-0.1.5.jar"}
```

Sample scripts

The following example PySpark scripts can be used to test querying S3 tables with an AWS Glue job. These scripts connect to your table bucket and runs queries to: create a new namespace, create

a sample table, insert data into the table, and return the table data. To use the scripts, replace the *placeholder values* with the information for you own table bucket.

Choose from the following scripts based on your S3 Tables access method.

S3 Tables integration with AWS analytics services

```
from pyspark.sql import SparkSession

spark = SparkSession.builder.appName("SparkIcebergSQL") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog","s3tables") \
    .config("spark.sql.catalog.s3tables", "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tables.catalog-impl",
 "org.apache.iceberg.aws.glue.GlueCatalog") \
    .config("spark.sql.catalog.s3tables.glue.id",
 "111122223333:s3tablescatalog/amzn-s3-demo-table-bucket") \
    .config("spark.sql.catalog.s3tables.warehouse", "s3://amzn-s3-demo-table-bucket/
bucket/amzn-s3-demo-table-bucket") \
    .getOrCreate()

namespace = "new_namespace"
table = "new_table"

spark.sql("SHOW DATABASES").show()

spark.sql(f"DESCRIBE NAMESPACE {namespace}").show()

spark.sql(f"""
    CREATE TABLE IF NOT EXISTS {namespace}.{table} (
       id INT,
       name STRING,
       value INT
    )
""")

spark.sql(f"""
    INSERT INTO {namespace}.{table}
    VALUES
       (1, 'ABC', 100),
       (2, 'XYZ', 200)
```

```
""")

spark.sql(f"SELECT * FROM {namespace}.{table} LIMIT 10").show()
```

Amazon S3 Tables Iceberg REST endpoint

```
from pyspark.sql import SparkSession

spark = SparkSession.builder.appName("glue-s3-tables-rest") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog", "s3_rest_catalog") \
    .config("spark.sql.catalog.s3_rest_catalog",
 "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3_rest_catalog.type", "rest") \
    .config("spark.sql.catalog.s3_rest_catalog.uri", "https://
s3tables.Region.amazonaws.com/iceberg") \
    .config("spark.sql.catalog.s3_rest_catalog.warehouse",
 "arn:aws:s3tables:Region:111122223333:bucket/amzn-s3-demo-table-bucket") \
    .config("spark.sql.catalog.s3_rest_catalog.rest.sigv4-enabled", "true") \
    .config("spark.sql.catalog.s3_rest_catalog.rest.signing-name", "s3tables") \
    .config("spark.sql.catalog.s3_rest_catalog.rest.signing-region", "Region") \
    .config('spark.sql.catalog.s3_rest_catalog.io-
impl','org.apache.iceberg.aws.s3.S3FileIO') \
    .config('spark.sql.catalog.s3_rest_catalog.rest-metrics-reporting-
enabled','false') \
    .getOrCreate()

namespace = "s3_tables_rest_namespace"
table = "new_table_s3_rest"

spark.sql("SHOW DATABASES").show()

spark.sql(f"DESCRIBE NAMESPACE {namespace}").show()

spark.sql(f"""
    CREATE TABLE IF NOT EXISTS {namespace}.{table} (
       id INT,
       name STRING,
       value INT
    )
```

```
""")

spark.sql(f"""
    INSERT INTO {namespace}.{table}
    VALUES
       (1, 'ABC', 100),
       (2, 'XYZ', 200)
""")

spark.sql(f"SELECT * FROM {namespace}.{table} LIMIT 10").show()
```

Amazon S3 Tables Catalog for Apache Iceberg

```
from pyspark.sql import SparkSession

#Spark session configurations
spark = SparkSession.builder.appName("glue-s3-tables") \
    .config("spark.jars.packages", "org.apache.iceberg:iceberg-spark-
runtime-3.4_2.12:1.4.2") \
    .config("spark.sql.extensions",
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .config("spark.sql.defaultCatalog", "s3tablesbucket") \
    .config("spark.sql.catalog.s3tablesbucket",
 "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tablesbucket.catalog-impl",
 "software.amazon.s3tables.iceberg.S3TablesCatalog") \
    .config("spark.sql.catalog.s3tablesbucket.warehouse",
 "arn:aws:s3tables:Region:111122223333:bucket/amzn-s3-demo-table-bucket") \
    .getOrCreate()

#Script
namespace = "new_namespace"
table = "new_table"

spark.sql(f"CREATE NAMESPACE IF NOT EXISTS s3tablesbucket.{namespace}")
spark.sql(f"DESCRIBE NAMESPACE {namespace}").show()

spark.sql(f"""
    CREATE TABLE IF NOT EXISTS {namespace}.{table} (
       id INT,
       name STRING,
```

```
        value INT
    )
""")

spark.sql(f"""
    INSERT INTO {namespace}.{table}
    VALUES
        (1, 'ABC', 100),
        (2, 'XYZ', 200)
""")

spark.sql(f"SELECT * FROM {namespace}.{table} LIMIT 10").show()
```

Step 3 – Create a AWS Glue job that queries tables

The following procedures show how to setup AWS Glue jobs that connect to your S3 table buckets. You can do this using the AWS CLI or using the console with AWS Glue Studio script editor. For more information, see Authoring jobs in AWS Glue in the *AWS Glue User Guide*.

Using AWS Glue Studio script editor

The following procedure shows how to use the AWS Glue Studio script editor to create an ETL job that queries your S3 tables.

Prerequisites

- Step 1 – Prerequisites
- Step 2 – Create a script to connect to table buckets

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. From the Navigation pane, choose **ETL jobs**.
3. Choose **Script editor**, then choose **Upload script** and upload the PySpark script you created to query S3 tables.
4. Select the **Job details** tab and enter the following for **Basic properties**.
   - For **Name**, enter a name for the job.
   - For **IAM Role**, select the role you created for AWS Glue.
5. (Optional) If you are using the Amazon S3 Tables Catalog for Apache Iceberg access method, expand **Advanced properties** and for **Dependent JARs path**, enter the S3 URI of the client

catalog jar your uploaded to an S3 bucket as a prerequisite. For example, s3://*amzn-s3-demo-bucket1*/*jars*/s3-tables-catalog-for-iceberg-runtime-*0.1.5*.jar

6. Choose **Save** to create the job.
7. Choose **Run** start the job, and review the job status under the **Runs** tab.

Using the AWS CLI

The following procedure shows how to use the AWS CLI to create an ETL job that queries your S3 tables. To use the commands replace the *placeholder values* with your own.

Prerequisites

- Step 1 – Prerequisites
- Step 2 – Create a script to connect to table buckets and upload it to an S3 bucket.

1. Create an AWS Glue job.

```
aws glue create-job \
--name etl-tables-job \
--role arn:aws:iam::111122223333:role/AWSGlueServiceRole \
--command '{
    "Name": "glueetl",
    "ScriptLocation": "s3://amzn-s3-demo-bucket1/scripts/glue-etl-query.py",
    "PythonVersion": "3"
}' \
--default-arguments '{
    "--job-language": "python",
    "--class": "GlueApp"
}' \
--glue-version "5.0"
```

> **Note**
>
> (Optional) If you are using the Amazon S3 Tables Catalog for Apache Iceberg access method, add the client catalog JAR to the `--default-arguments` using the `--extra-jars` parameter. Replace the *input placeholders* with your own when you add the parameter.

```
                                "--extra-jars": "s3://amzn-s3-demo-bucket/jar-
path/s3-tables-catalog-for-iceberg-runtime-0.1.5.jar"
```

2. Start your job.

```
aws glue start-job-run \
--job-name etl-tables-job
```

3. To review you job status, copy the run ID from the previous command and enter it into the following command.

```
aws glue get-job-run --job-name etl-tables-job \
--run-id jr_ec9a8a302e71f8483060f87b6c309601ea9ee9c1ffc2db56706dfcceb3d0e1ad
```

Getting started querying S3 Tables with Amazon SageMaker Unified Studio

Amazon SageMaker Unified Studio is a comprehensive analytics service that enables you to query and derive insights from your data using SQL, natural language, and interactive notebooks. It supports team collaboration and analysis workflows across AWS data repositories and third-party sources within a unified interface. SageMaker Unified Studio integrates directly with S3 Tables, providing a seamless transition from data storage to analysis within the Amazon S3 console.

You can integrate S3 Tables with SageMaker Unified Studio through the Amazon S3 console or SageMaker Unified Studio console.

For setup through the SageMaker Unified Studio console, see the SageMaker Unified Studio documentation.

Requirements for querying S3 Tables with SageMaker Unified Studio

Using SageMaker Unified Studio with S3 Tables requires the following:

- Your table buckets have been integrated with AWS analytics services in the current Region. For more information, see Integrating S3 Tables with AWS analytics services.
- You are using an IAM role with permissions to create and view resources in SageMaker Unified Studio. For more information, see Setup IAM-based domains in SageMaker Unified Studio.

- You have a SageMaker domain and project. For more information, see Domains in the *SageMaker Unified Studio Administrator Guide*, and Projects in the *SageMaker Unified Studio User Guide*.

If you haven't already performed these actions or created these resources, S3 Tables can automatically complete this set up for you so you can begin querying with SageMaker Unified Studio.

Getting started querying S3 Tables with SageMaker Unified Studio

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. On the **Table buckets** page, choose the bucket that contains the table that you want to query.
4. On the bucket details page, select the table that you want to query.
5. Choose **Query**.
6. Then, choose **Query table in SageMaker Unified Studio**.

    a. If you've already configured SageMaker Unified Studio for your tables the SageMaker Unified Studio console opens to the query editor with a sample SELECT query loaded for you. Modify this query as needed for your use case.

    b. If you haven't already configured SageMaker Unified Studio for S3 Tables, a set up page appears with a single step to enable Integration with AWS analytics services which integrates your tables with services like SageMaker Unified Studio. This step will execute automatically then you will be redirected to a page in the SageMaker Unified Studio console with the following options to configure your account for querying S3 Tables:

        i. In **Setting you up as an administrator**, your current federated IAM role is selected. If your current role does not already have the required permissions, you will need to setup an IAM-based domain in SageMaker Unified Studio and assign permissions to your role so you can login to SageMaker Unified Studio.

        ii. In **Project data and administrative control**, select **Auto-create a new role with required permissions** to automatically create a role with the required permissions, or select **Use an existing role** and choose a role. If the chosen role does not already have the required permissions, you will need to setup an IAM-based domain in SageMaker Unified Studio and assign permissions to your admin execution role so you can access data in SageMaker Unified Studio.

iii. In **Data encryption** select **Use AWS owned key** to let AWS own and manage a key for you or **Choose a different AWS AWS KMS key (advanced)** to use an existing key or to create a new one.

iv. Select **Set up SageMaker Unified Studio**.

v. Next, the SageMaker Unified Studio console opens to the query editor with a sample `SELECT` query loaded for you. Modify this query as needed for your use case.

In the query editor, the **Catalog** field should be populated with `s3tablescatalog/` followed by the name of your table bucket, for example, `s3tablescatalog/amzn-s3-demo-table-bucket`. The **Database** field is populated with the namespace where your table is stored.

Streaming tables with Amazon MSK

Streaming tables are Apache Iceberg tables in your table buckets that Amazon Managed Streaming for Apache Kafka (Amazon MSK) writes to continuously. Unlike tables that you create and write to directly, a streaming table is created and populated by Amazon MSK. Amazon MSK Express brokers deliver records from a Kafka topic as Apache Parquet data files and commit them to the table, making the data available to query within minutes of being produced. A single streaming table scales to Amazon MSK delivery throughput of up to 10 GBps without manual scaling.

Because Amazon MSK owns the writes, a streaming table is read-only. You have full read access from any Iceberg-compatible engine, and you control table maintenance and read access the same way as for other tables in your table bucket.

You create a streaming table by configuring an Amazon MSK delivery channel rather than by calling `CreateTable`. Amazon MSK creates the table on first delivery. For how to configure the channel, including the source topic, data freshness, dead-letter queue, and the AWS Glue Schema Registry, see Amazon MSK data delivery in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

What you can and can't do with streaming tables

With a streaming table, you can do the following:

- Query the table with Amazon Athena, Amazon Redshift, Amazon EMR, Apache Spark, or any other Iceberg-compatible query engine.

- Grant read access with AWS Identity and Access Management (IAM) policies, table bucket policies, and AWS Lake Formation.
- Configure the automated S3 Tables maintenance jobs: compaction, snapshot expiration, and unreferenced file removal.
- Configure record expiration on the `timestamptz` partition column to automatically delete records older than a retention period that you specify.
- Delete the table with `DeleteTable`. After you delete the table, Amazon MSK delivery fails. To resume delivery, recreate the Amazon MSK channel.

With a streaming table, you can't do the following:

- Write to the table directly (`INSERT`, `UPDATE`, `MERGE`, `COPY INTO`, or Iceberg writes from your own engines).
- Change the schema, partition spec, sort order, or table properties.
- Delete individual rows outside of the record expiration job.
- Backfill records that were produced to the Kafka topic before the Amazon MSK channel was enabled.

Permissions to query streaming tables

Read access to a streaming table works the same as for any other Amazon S3 table. You grant it with IAM policies, table bucket policies, and AWS Lake Formation. The following example policy allows you to query a streaming table. If the table is encrypted with an AWS AWS KMS key, the second statement grants the `kms:Decrypt` permission on that key.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"PermissionsToQueryStreamingTables",
         "Effect":"Allow",
         "Action":[
             "s3tables:GetTable",
             "s3tables:GetTableData",
             "s3tables:GetTableMetadataLocation"
         ],
         "Resource":[
```

```
            "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket",
            "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket/
table/*"
         ]
      },
      {
         "Sid":"PermissionsToDecryptTableData",
         "Effect":"Allow",
         "Action":[
             "kms:Decrypt"
         ],
         "Resource":[
            "arn:aws:kms:us-east-1:111122223333:key/01234567-89ab-
cdef-0123-456789abcdef"
         ]
       }
    ]
}
```

The permissions that Amazon MSK needs to create the table and write to it belong to the Amazon MSK service role. For those permissions, see IAM permissions for Amazon MSK data delivery in the *Amazon Managed Streaming for Apache Kafka Developer Guide*. If your table bucket is in a different AWS account from the Amazon MSK cluster, the bucket owner must attach a table bucket policy that grants the Amazon MSK service role the actions it needs. For more information, see Managing table bucket policies.

Working with Apache Iceberg V3

Apache Iceberg Version 3 (V3) is the latest version of the Apache Iceberg table format specification, introducing advanced capabilities for building petabyte-scale data lakes with improved performance and reduced operational overhead. V3 addresses common performance bottlenecks encountered with Version 2 (V2), particularly around batch updates and compliance deletes.

AWS provides support for the capabilities defined in the Apache Iceberg Version 3 (V3) specification. These capabilities include deletion vectors, row lineage, and column default values. They also include the following data types:

- variant
- geometry
- geography

- unknown
- nanosecond-precision timestamps without a time zone
- nanosecond-precision timestamps with a time zone

S3 Tables support all of the data types that V3 introduces.

You can use Apache Iceberg V3 with Apache Spark on Amazon EMR, AWS Glue ETL, Amazon SageMaker Unified Studio Notebooks, and tables in AWS Glue Data Catalog, including Amazon S3 Tables.

Key Features in V3

Deletion Vectors

Replaces V2's positional delete files with an efficient binary format stored as Puffin files. This eliminates write amplification from random batch updates and GDPR compliance deletes, significantly reducing the overhead of maintaining fresh data. Organizations processing high-frequency updates will see immediate improvements in write performance and reduced storage costs from fewer small files.

Row-lineage

Enables precise change tracking at the row level. Your downstream systems can process changes incrementally, speeding up data pipelines and reducing compute costs for change data capture (CDC) workflows. This built-in capability eliminates the need for custom change tracking implementations.

Variant data type

With the variant data type, you can write semi-structured data like JSON directly in Iceberg tables without defining a fixed schema in advance. V3 compatible engines shred your semi-structured data into hidden columns as you write it, generating Parquet column statistics that query engines use for optimizations like file pruning. This reduces the data your analytical queries scan. S3 Tables provides ongoing table maintenance for variant columns, including compaction, so you can consolidate data from semi-structured sources into larger files that Iceberg engines can read efficiently.

Geospatial data types

The `geometry` and `geography` types store points, lines, and polygons as native columns instead of encoded strings or paired latitude and longitude values. `geometry` operates on a

Cartesian plane. `geography` treats coordinates as spherical coordinates on a spheroid. Both types recognize spatial reference system identifier (SRID) 0 and SRID 4326. Workloads such as fleet tracking and asset mapping can filter on location at query time. For examples, see the section called “Using the geospatial data types”.

Nanosecond-precision timestamps

`timestamp(9)` records event times to nanosecond precision without a time zone, and `timestamptz(9)` records them with a time zone. Telemetry, sensor fusion, and financial workloads can store timestamps at source precision instead of encoding them as integers and converting them on read. For examples, see the section called “Using nanosecond-precision timestamps”.

Column default values

A field can carry an `initial-default` value, used to populate the field for records written before the field was added to the schema, and a `write-default` value, used when a writer omits the column. Column default values populate a newly added column for existing rows, with no backfill. For examples, see the section called “Using column default values”.

> **Important**
>
> The V3 specification requires that all columns of unknown, `variant`, `geometry`, and `geography` type default to null. Non-null `initial-default` or `write-default` values are invalid for those four types.

Unknown type

The `unknown` type represents a column whose type has not yet been resolved. It must be optional with null defaults and is not stored in data files, which makes it useful for placeholder columns during schema evolution and when migrating from other table formats. For examples, see the section called “Using the unknown type”.

Version Compatibility

V3 maintains backward compatibility with V2 tables. AWS services support both V2 and V3 tables simultaneously, allowing you to:

- Run queries across both V2 and V3 tables

- Upgrade existing V2 tables to V3 without data rewrites
- Execute time travel queries that span V2 and V3 snapshots
- Use schema evolution and hidden partitioning across table versions

> **Important**
>
> V3 is a one-way upgrade. Once a table is upgraded from V2 to V3, it cannot be downgraded back to V2 through standard operations.

Getting Started with V3

Prerequisites

Before working with V3 tables, ensure you have:

- An AWS account with appropriate IAM permissions
- Access to one or more AWS analytics services (EMR, Glue, Amazon SageMaker Unified Studio Notebooks, or S3 Tables)
- To use the `geometry` and `geography` types in Apache Spark, set `spark.sql.geospatial.enabled=true` in your Spark configuration. On AWS Glue, set it through the job's `--conf` argument. The variant, unknown, nanosecond timestamp, and column default value features need no additional Spark configuration.
- An S3 bucket for storing table data and metadata
- A table bucket to get started with S3 Tables or a general purpose S3 bucket if you are building your own Iceberg infrastructure
- AWS Glue catalog configured

Creating V3 Tables

Creating New V3 Tables

To create a new Iceberg V3 table, set the format-version table property to 3.

Using Spark SQL:

```
CREATE TABLE IF NOT EXISTS myns.orders_v3 (
    order_id bigint,
    customer_id string,
    order_date date,
    total_amount decimal(10,2),
    status string,
    created_at timestamp
)
USING iceberg
TBLPROPERTIES (
    'format-version' = '3'
)
```

Upgrading V2 Tables to V3

You can upgrade existing V2 tables to V3 atomically without rewriting data.

Using Spark SQL:

```
ALTER TABLE myns.existing_table
SET TBLPROPERTIES ('format-version' = '3')
```

> **Important**
>
> V3 is a one-way upgrade. Once a table is upgraded from V2 to V3, it cannot be downgraded back to V2 through standard operations. Before you upgrade, verify that every engine that reads or writes the table supports V3. Amazon Athena can't read V3 tables. For engine support, see Troubleshooting.

What happens during upgrade:

- A new metadata snapshot is created atomically
- Existing Parquet data files are reused
- Row-lineage fields are added to the table metadata
- The next compaction will remove old V2 delete files
- New modifications will use V3's Deletion Vector files

- The upgrade does not perform a historical backfill of row-lineage change tracking records

Enabling Deletion Vectors

To take advantage of Deletion Vectors for updates, deletes, and merges, configure your write mode.

Using Spark SQL:

```
ALTER TABLE myns.orders_v3
SET TBLPROPERTIES ('format-version' = '3',
                   'write.delete.mode' = 'merge-on-read',
                   'write.update.mode' = 'merge-on-read',
                   'write.merge.mode' = 'merge-on-read'
                  )
```

These settings ensure that update, delete, and merge operations create Deletion Vector files instead of rewriting entire data files.

Leveraging Row-lineage for Change Tracking

V3 automatically adds row-lineage metadata fields to track changes.

Using Spark SQL:

```
# Query with parameter value provided
last_processed_sequence = 47

SELECT
    id,
    data,
    _row_id,
    _last_updated_sequence_number
FROM myns.orders_v3
WHERE _last_updated_sequence_number > :last_processed_sequence
```

The _row_id field uniquely identifies each row, while _last_updated_sequence_number tracks when the row was last modified. Use these fields to:

- Identify changed rows for incremental processing
- Track data lineage for compliance
- Optimize CDC pipelines
- Reduce compute costs by processing only changes

Using the variant data type

> **Important**
>
> The variant data type is available only in specific AWS Regions. For the full list of supported Regions, see the section called “Availability”.

With the variant data type, you can write semi-structured data like JSON directly in your Iceberg tables without defining a fixed schema in advance. You can write data faster while still getting efficient analytical query performance. Iceberg V3 compatible engines shred your semi-structured data into hidden columns as you write it. These hidden columns generate Parquet column statistics that query engines use for optimizations like file pruning.

Creating a table with a variant column using Spark SQL:

```
CREATE TABLE IF NOT EXISTS myns.events (
    event_id bigint,
    event_timestamp timestamp,
    source string,
    event_data VARIANT
)
USING iceberg
TBLPROPERTIES (
    'format-version' = '3'
)
```

Inserting semi-structured data into the variant column:

```
INSERT INTO myns.events VALUES (
```

```
    1,
    current_timestamp(),
    'web-app',
    PARSE_JSON('{"user_id": "u-1234", "action": "page_view", "page": "/products",
 "duration_ms": 350}')
);

INSERT INTO myns.events VALUES (
    2,
    current_timestamp(),
    'mobile-app',
    PARSE_JSON('{"user_id": "u-5678", "action": "purchase", "items": [{"sku": "A100",
 "qty": 2}], "total": 49.99}')
);
```

With S3 Tables, table maintenance for variant columns, including compaction, runs automatically. Compaction consolidates data from semi-structured sources from small files into larger files that Iceberg engines can read more efficiently, improving query performance over time.

Using the geospatial data types

Creating a table with geospatial columns using Spark SQL:

```
CREATE TABLE IF NOT EXISTS myns.vehicle_telemetry (
    vehicle_id     string,
    event_time     timestamp,
    position       geometry(4326),
    service_area   geography(4326),
    firmware       string
)
USING iceberg
TBLPROPERTIES ('format-version' = '3')
```

Inserting geospatial values:

```
INSERT INTO myns.vehicle_telemetry VALUES (
    'v-1024',
    TIMESTAMP '2026-09-18 14:22:31.123456',
```

```
    ST_SetSrid(ST_GeomFromWKT('POINT (1 2)'), 4326),
    ST_SetSrid(ST_GeogFromWKT('POLYGON ((0 0, 10 0, 10 10, 0 10, 0 0))'), 4326),
    'fw-3.2.1'
)
```

Filtering on location:

```
SELECT vehicle_id, event_time
FROM myns.vehicle_telemetry
WHERE ST_Intersects(
        position,
        ST_SetSrid(ST_GeomFromWKT('POLYGON ((0 0, 10 0, 10 10, 0 10, 0 0))'), 4326)
      )
```

Note

Existing columns that hold encoded coordinates, such as paired `double` values or WKT strings, are not converted when you upgrade a table to V3. To adopt the geospatial types for existing data, add a column of the new type and populate it.

Note

Geodesic spatial predicates over `geography` are engine-dependent. Spatial predicates in Apache Spark on Amazon EMR and AWS Glue operate on `geometry`.

Using nanosecond-precision timestamps

Creating a table with a nanosecond timestamp column using Spark SQL:

```
CREATE TABLE IF NOT EXISTS myns.trades (
    trade_id     bigint,
    executed_at  timestamptz(9),
    symbol       string,
    price        decimal(18,8)
```

```
)
USING iceberg
TBLPROPERTIES ('format-version' = '3')
```

`timestamp(9)` stores a timestamp without a time zone. `timestamptz(9)` stores one with a time zone.

> **Note**
>
> Reading or writing a nanosecond column with an engine that supports only microsecond precision truncates the value. Confirm that your engine supports nanosecond precision before you rely on it.

Using column default values

Adding a column with a default value using Spark SQL:

```
ALTER TABLE myns.orders
ADD COLUMN currency string DEFAULT 'USD'
```

Rows written before the `currency` column was added return USD rather than null, and no data files are rewritten. The value is stored once in the table's schema metadata as the field's `initial-default` and substituted at read time.

> **Note**
>
> Columns of unknown, `variant`, `geometry`, and `geography` type must default to null, so a non-null default value is invalid for them. For examples of those types, see the section called “Using the unknown type”, the section called “Using the variant data type”, and the section called “Using the geospatial data types”.

Using the unknown type

Creating a table with an unknown column using Spark SQL:

```
CREATE TABLE IF NOT EXISTS myns.staging_events (
    event_id   bigint,
    payload    string,
    reserved   unknown
)
USING iceberg
TBLPROPERTIES ('format-version' = '3')
```

An unknown column must be optional, always reads as null, and is not written to data files. You can later evolve it to a concrete type.

Best Practices for V3

When to Use V3

Consider upgrading to or starting with V3 when:

- You perform frequent batch updates or deletes
- You need to meet GDPR or compliance delete requirements
- Your workloads involve high-frequency upserts
- You require efficient CDC workflows
- You want to reduce storage costs from small files
- You need better change tracking capabilities

Optimizing Write Performance

- Enable Deletion Vectors for update-heavy workloads:

```
SET TBLPROPERTIES (
'write.delete.mode' = 'merge-on-read',
'write.update.mode' = 'merge-on-read',
'write.merge.mode' = 'merge-on-read'
)
```

- Configure appropriate file sizes:

```
SET TBLPROPERTIES (
'write.target-file-size-bytes' = '536870912'  — 512 MB
)
```

Optimizing Read Performance

- Leverage row-lineage for incremental processing
- Use time travel to access historical data without copying
- Enable statistics collection for better query planning

Migration Strategy

When migrating from V2 to V3:

- Test in non-production first - Validate upgrade process and performance
- Upgrade during low-activity periods - Minimize impact on concurrent operations
- Monitor initial performance - Track metrics after upgrade
- Run compaction - Consolidate delete files after upgrade
- Update documentation - Reflect V3 features in team documentation

Compatibility Considerations

- Engine versions - Ensure all engines accessing the table support V3
- Third-party tools - Verify V3 compatibility before upgrading
- Backup strategy - Test snapshot-based recovery procedures
- Monitoring - Update monitoring dashboards for V3-specific metrics

The V3 data types are supported only for tables that use the Parquet data file format. They are not supported for tables that use the ORC or Avro data file formats.

For V3 tables, the sort and Z-order compaction strategies don't support the variant, geometry, geography, and nanosecond-precision timestamp data types.

Considerations for compaction

Compaction writes shredded variant Parquet files by default. Older readers that do not support shredding might fail to read compacted files. You can disable shredding by setting the table property `write.variant.shredding.enabled=false`.

Troubleshooting

Common Issues

Error: "format-version 3 is not supported"

- Check your query engine catalog for compatibility with Iceberg V3.
- Ensure that you are using the latest AWS service versions.
- Verify your engine version supports V3

  V3 support for Amazon AWS services is as follows:

Service	V3 Support	V3 variant support
EMR Spark	Release 7.12+	Release 8.0+
AWS Glue ETL	Version 5.1+	Version 6.0+
Amazon SageMaker Unified Studio Notebooks	Yes	No
AWS Glue: Iceberg REST API, Table Maintenance	Yes	No
Amazon S3 Tables: Iceberg REST API, Table Maintenance	Yes	Yes*
Amazon Athena (Trino)	No	No
Amazon Redshift	Patch 204+	No

*Partial Region availability

S3 Tables support all V3 data types.

Column default values are supported in S3 Tables. They are also supported in AWS Glue version 5.1 and later, and in Amazon Redshift.

Performance degradation after upgrade

- Verify there are no compaction failures. See Logging and monitoring for S3 Tables for more details.
- Check if Deletion Vectors are enabled. Ensure the following properties are set:

```
SET TBLPROPERTIES (
'write.delete.mode' = 'merge-on-read',
'write.update.mode' = 'merge-on-read',
'write.merge.mode' = 'merge-on-read'
)
```

- You can verify table properties with the following code:

```
DESCRIBE FORMATTED myns.orders_v3
```

- Review partition strategy. Over partitioning can lead to small files. Run the below query to get the average file size for your table:

```
SELECT avg(file_size_in_bytes) as avg_file_size_bytes
FROM myns.orders_v3.files
```

Incompatibility with third-party tools

- Verify tool supports V3 specification
- Consider maintaining V2 tables for unsupported tools
- Contact tool vendor for V3 support timeline

Getting Help

- AWS Support: Contact AWS Support for service-specific issues
- Apache Iceberg Community: Iceberg Slack
- AWS Documentation: AWS Analytics Documentation

Pricing

- Amazon EMR: Compute and storage pricing
- Amazon SageMaker pricing
- AWS Glue: Job run and Data Catalog pricing
- S3 Tables: Storage and request pricing

Availability

Apache Iceberg V3 support for deletion vectors and row lineage is available across all AWS Regions where Amazon EMR, AWS Glue Data Catalog, AWS Glue ETL, and S3 Tables operate.

Column default values and the geometry, geography, unknown, and nanosecond-precision timestamp data types are available in all AWS Regions where S3 Tables are available.

The variant data type in S3 Tables is available in the following AWS Regions: US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm), and South America (São Paulo).

Replicating S3 tables

Amazon S3 Tables support automatic replication of Apache Iceberg tables stored in Amazon S3 table buckets. Replication destinations can be within the same AWS Region, across multiple AWS

Regions, the same account, or to other AWS accounts. By configuring replication for your tables, you can maintain read-only replicas of your data across multiple locations. You can use replicas to enhance data availability, meet compliance requirements and increase access performance for distributed applications.

S3 Tables replication maintains data consistency by committing all table updates, including snapshots, metadata, and data files, to the destination table in the same order as the source table.

When to use S3 Tables replication

You can use S3 Tables replication for the following purposes:

- **Minimize latency** – If your customers are in two geographic locations, you can minimize latency when accessing tables by maintaining read replicas in AWS Regions that are geographically closer to your users.
- **Regulatory compliance** – You can maintain read replicas in specific geographic locations or AWS accounts, which might help you meet certain regulatory or compliance requirements. You can configure the replication destination table bucket to encrypt tables with different AWS KMS keys than the source.
- **Centralized analytics** – If you have data distributed across multiple AWS Regions, you can replicate Region-specific datasets to a centralized Region for unified reporting, cross-Region analysis, and machine learning model training. This eliminates the need to query across Regions or build custom data aggregation pipelines.
- **Testing and development environments** – You can create read replicas of production tables in separate AWS accounts or table buckets to provide realistic test data for development and QA teams. This isolates testing workloads from production systems while ensuring test environments have current, production-like data without manual exports or data synchronization processes.

Features

S3 Tables replication offers the following features.

Read-only replicas for S3 Tables

S3 Tables replication creates read-only replicas of your Apache Iceberg tables across table buckets. You can query replicas independently using any Iceberg-compatible engine.

Automatically maintained replicas

The S3 Tables replication service automatically maintains replica tables. Replication typically updates replicas within minutes of updates to the source. S3 Tables commits all updates in the same order as the source table to maintain consistency.

Replication to multiple destinations

You can replicate the same table to multiple destination table buckets. Replication destinations can be within the same AWS Region, across multiple AWS Regions, in the same AWS account, or in other AWS accounts.

Independent snapshot retention

Snapshot expiration for replica tables is independent of the source table, allowing you to set different retention periods on replica tables if needed. For example, you can configure your source table to retain snapshots for 30 days while setting a 90-day retention period for replica tables. If you configure a longer retention period on replicas, snapshots that expire at the source remain available and queryable in replicas. This configuration provides extended time-travel capabilities for historical analysis.

Maintain replica tables in lower-cost storage tiers

You can configure destination table buckets to use the S3 Intelligent-Tiering storage class, which automatically optimizes storage costs based on access patterns without performance impact or operational overhead. S3 Intelligent-Tiering is well-suited for replica tables that may be accessed less frequently.

For more information about S3 Tables replication, see the following topics.

Topics

- How S3 Tables replication works
- Setting up S3 Tables replication
- Managing S3 Tables replication

How S3 Tables replication works

S3 Tables replication creates read-only replicas of your Apache Iceberg tables across Regions and AWS accounts. Replica tables are maintained automatically by the S3 Tables service and

contain the complete data, metadata, and snapshot history from your source table, making them queryable using any Iceberg-compatible engine for analytics and time-travel operations.

When you configure replication for a table, S3 Tables:

- Creates a read-only replica table in each destination table bucket with the same name and namespace as the source table.
- Backfills the replica with the latest state of the source table
- Monitors the source table for new updates
- Commits all updates to replicas in the same order as the source to maintain consistency

For more information, see the following sections.

Topics

- What is replicated
- How data is replicated
- Snapshot replication
- Considerations and limitations

What is replicated

The following table components are replicated:

- **Table snapshots** – All snapshots, including compacted snapshots, are replicated in chronological order, maintaining parent-child relationships and sequence numbers from the source table. This ensures that replica tables provide the same time-travel capabilities as source tables.
- **Table data** – All data files referenced by table snapshots are replicated to the destination Region. This includes:
  - **Metadata files** – Table metadata.json files, manifests, manifest lists, partition statistics and table statistics.
  - **Delete files** – All delete files are replicated to maintain data accuracy in replica tables.
  - **Data files** – All data files referenced by manifests are replicated.
- **Table metadata** – Complete metadata replication, including schema information (current and historical), partition specifications, sort orders, and table properties.

- **Schema Information** – All table schemas are replicated, including the current schema and historical schema versions. This ensures that queries against replica tables use the correct column definitions, data types, and field mappings. The replication process maintains schema evolution history, allowing time travel queries to work correctly on replica tables.
- **Partition Specifications** – Current and historical partition specifications are replicated, ensuring replica tables maintain the same partitioning strategy as source tables.
- **Sort Orders** – Table sort orders are replicated to maintain query performance optimizations.

How data is replicated

Replication determines a valid state for replica tables by comparing Apache Iceberg table metadata between the source and replica tables. Replication processes metadata in three categories to update your replica table.

For table metadata

For versioned metadata fields, replication merges values from the source table into the replica table's arrays for the following fields:

- `snapshots` – Merges all snapshots from the source table into the replica table's snapshots array by snapshot-id.
- `snapshot-log` – Merges snapshot logs from the source table into the replica table's snapshot-log array, sorted by timestamp and snapshot-id.
- `sort-orders` – Merges sort order definitions from the source table into the replica table's sort-orders array by order-id.
- `partition-specs` – Merges partition specifications from the source table into the replica table's partition-specs array by spec-id.
- `schemas` – Merges schema definitions from the source table into the replica table's schemas array by schema-id.

For table configuration

For fields that represent table configuration, replication copies values directly from the source table:

- `properties`

- `partition-statistics`
- `statistics`

Current table state is also transferred from the source table:

- `current-snapshot-id`
- `current-schema-id`
- `last-column-id`
- `last-partition-id`
- `last-sequence-number`
- `default-sort-order-id`
- `next-row-id` (Iceberg V3)
- `encryption-keys` (Iceberg V3)

Replica-specific state

The following fields are calculated from merged data and updated for the replica table:

- `location` is updated during replication to point to the correct file location in the replica table bucket, ensuring that all file references are valid in the destination environment.
- `metadata-log` contains all destination metadata filenames and is updated after every successful replication with the current metadata filename.
- All file paths are modified to point to the replica table locations.

Snapshot replication

S3 Tables replication maintains complete snapshot history across Regions by replicating all table snapshots in the same commit order as the source table. The parent-child relationships from the source table are preserved in the replica table.

Snapshot retention

You can configure a custom snapshot retention period for your replicated tables that differs from the retention period of the source. This means that even if snapshots are expired and no longer available in the source table, they can be preserved in replicas.

For example, if your source table has a 30-day snapshot retention period but your replica table is configured with a 90-day retention period, the replica will maintain snapshots from the previous two months that are no longer available in the source table.

Snapshots that you manually expired at the source table are also preserved in the replica table. For example, if you expired snapshots from February at the source table using a Spark procedure, you can still time travel to the snapshots in the replica table.

Considerations and limitations

The following considerations apply to replicated tables:

- S3 Tables replicates both Iceberg V2 and V3 tables. However, replication of upgraded tables (V2 → V3) is not supported.
- Metadata files larger than 500MB are not supported.
- While table updates are typically replicated within minutes, replication can take longer depending on the size of the table update to be replicated, for example, when replication starts backfilling.
- Tables with tags or branches are not supported.
- Replication is not supported for Amazon S3 Metadata tables or other AWS-generated system tables.
- All table snapshots, including compacted snapshots, are replicated from the source table. As a result, compaction is not supported on replica tables.

Setting up S3 Tables replication

You can set up replication to automatically create table replicas from a source table to up to five destination table buckets. Replication can be configured at the bucket level (applying to all tables in the bucket) or at the table level (for specific tables). This topic explains how to configure replication using the Amazon S3 console or the AWS Command Line Interface (AWS CLI).

For more information about setting up replication, see the following topics.

Topics

- Prerequisites for setting up replication
- Understanding replication configurations

- Choosing between bucket-level and table-level replication
- Setting up replication by using the Amazon S3 console
- Setting up replication by using the AWS CLI

Prerequisites for setting up replication

Before you configure replication, ensure you have the following:

Required resources

- **Source table bucket** – The table bucket containing the table(s) you want to replicate
- **Destination table bucket(s)** – One or more table buckets where you want to replicate your tables (up to 5 destination table buckets)
- **Source table(s)** – Existing tables in your source table bucket to replicate
- **IAM role(s)** – An IAM role that grants Amazon S3 permissions to replicate tables on your behalf

Required permissions

The IAM identity that you use to set up replication must have the following permissions:

For bucket-level replication:

- `s3tables:PutTableBucketReplication` on the source table bucket
- `s3tables:GetTableBucketReplication` on the source table bucket
- `iam:PassRole` for the replication IAM role

For table-level replication:

- `s3tables:PutTableReplication` on the source table
- `s3tables:GetTableReplication` on the source table
- `iam:PassRole` for the replication IAM role

For cross-account replication:

- Permissions from the destination account's bucket policy

Additional requirements for cross-account replication

If your source and destination table buckets are in different AWS accounts, you also need:

- A bucket policy on the destination table bucket that grants the source account permissions to replicate tables
- The destination account ID and table bucket Amazon Resource Name (ARN)

Additional requirements for encrypted tables

If you want to encrypt replica tables with AWS KMS:

- A KMS key in the destination Region
- Permissions to use the KMS key in your IAM replication role
- A KMS key policy that allows the replication role to encrypt data

Understanding replication configurations

A replication configuration defines how Amazon S3 replicates tables from your source table bucket. Replication can be configured at two levels:

Bucket-level replication

A bucket-level replication configuration applies to all tables in the source table bucket. When you configure bucket-level replication, Amazon S3 automatically replicates any existing tables and any new tables created in the bucket.

Use bucket-level replication when:

- You want to replicate all tables in a bucket
- You want consistent replication behavior across all tables
- You want to simplify management by having a single configuration

Table-level replication

A table-level replication configuration applies to a specific table. Table-level configurations override bucket-level configurations for that specific table.

Use table-level replication when:

- You want to replicate only specific tables
- You need different replication destinations for different tables
- You want to override a bucket-level configuration for certain tables

Replication configuration elements

Each replication configuration contains:

- **IAM role** – The role that Amazon S3 assumes to perform replication operations
- **Rules** – One or more replication rules (limited to 1 rule at launch). Each rule contains:
  - **Destinations** – List of destination table bucket ARNs (up to 5 destinations)
  - **Status** – Whether the rule is enabled or disabled
- **Version token** – A token used to prevent write conflicts when updating configurations

Choosing between bucket-level and table-level replication

Configuration precedence

When both bucket-level and table-level configurations exist:

- Table-level configuration takes precedence for that specific table.
- Other tables follow the bucket-level configuration.

Setting up replication by using the Amazon S3 console

This procedure shows you how to configure replication using the Amazon S3 console.

To set up bucket-level replication

This procedure shows you how to create a table bucket replication configuration using the Amazon S3 console. A table bucket replication configuration applies to all tables in the source table bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Table buckets**.
3. In the **Table buckets** list, choose the name of the table bucket for which you want to configure replication.

4. Choose the **Management** tab.
5. In the **Table bucket replication configuration** section, choose **Create table bucket replication configuration**.
6. In the **Destination** section, configure your replication destinations:

   a. In the **Table bucket ARN** field, enter the ARN of the destination table bucket. The format is: `arn:aws:s3tables:region:account-id:bucket/table-bucket-name`

   Alternatively, choose **Browse S3** to select a table bucket from your account.

   b. (Optional) To add additional destinations, choose **Add destination**. You can add up to 4 more table buckets for a total of 5 destinations.
7. In the **IAM role** section, configure the replication role:

   a. For **IAM role selection method**, choose one of the following options:

   - **Create new IAM role** – Amazon S3 creates a new role with the necessary permissions for replication.
   - **Choose from existing IAM roles** – Select an existing role that has the required replication permissions.
   - **Enter IAM role ARN** – Manually enter the ARN of an existing IAM role.

   b. If you chose **Choose from existing IAM roles**, select a role from the **IAM role** dropdown list.

   c. (Optional) Choose **View** to review the selected role's permissions in the IAM console.
8. Choose **Create replication configuration**.

   After you create the replication configuration, Amazon S3 begins the initial backfill process. You can monitor the replication status in the **Table replication status** section, which displays information about each destination including replication status, destination table ARN, and last replicated metadata.

To set up table-level replication

This procedure shows you how to create a table-level replication configuration using the Amazon S3 console. A table replication configuration applies to a specific table and overrides any bucket-level replication configuration for that table.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Table buckets**.
3. In the **Table buckets** list, choose the name of the table bucket that contains the table you want to replicate.
4. Choose the **Tables** tab.
5. In the **Tables** list, choose the name of the table that you want to replicate.
6. Choose the **Management** tab.
7. In the **Table replication configuration** section, choose **Create table replication configuration**.
8. In the **Destination** section, configure your replication destinations:

   a. In the **Table bucket ARN** field, enter the ARN of the destination table bucket. The format is: `arn:aws:s3tables:`*`region`*`:`*`account-id`*`:bucket/`*`table-bucket-name`*

   Alternatively, choose **Browse S3** to select a table bucket from your account.

   b. (Optional) To add additional destinations, choose **Add destination**. You can add up to 4 more table buckets for a total of 5 destinations.
9. In the **IAM role** section, configure the replication role:

   a. For **IAM role selection method**, choose one of the following options:

   - **Create new IAM role** – Amazon S3 creates a new role with the necessary permissions for replication.
   - **Choose from existing IAM roles** – Select an existing role that has the required replication permissions.
   - **Enter IAM role ARN** – Manually enter the ARN of an existing IAM role.

   b. If you chose **Choose from existing IAM roles**, select a role from the **IAM role** list.

   c. (Optional) Choose **View** to review the selected role's permissions in the IAM console.
10. Choose **Create replication configuration**.

What happens next?

After you create the replication configuration:

- Amazon S3 begins the initial backfill process, creating replica tables in each destination bucket

- The replication status changes to **Replicating** once backfill begins
- You can monitor replication progress on the **Management** tab
- Initial replication time depends on the size of your source table

Setting up replication by using the AWS CLI

This procedure shows you how to configure replication using the AWS CLI. Replace the account IDs, regions, and bucket names with your actual values. Add all destination buckets to the permissions.

Step 1: Create an IAM role for replication

First, create an IAM role that Amazon S3 can assume to replicate your tables.

1. Create a trust policy document that allows S3 Tables to assume the role. Save this as `trust-policy.json`:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "replication.s3tables.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Create the IAM role:

```
aws iam create-role \
    --role-name S3TablesReplicationRole \
    --assume-role-policy-document file://trust-policy.json \
    --description "Role for S3 Tables replication"
```

3. Create a permissions policy that grants replication permissions. Save this as `replication-permissions.json`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3tables:GetTable",
                "s3tables:GetTableMetadataLocation",
                "s3tables:GetTableMaintenanceConfiguration",
                "s3tables:GetTableData"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket-source/table/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3tables:ListTables"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket-source"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3tables:CreateTable",
                "s3tables:CreateNamespace"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:444455556666:bucket/amzn-s3-demo-table-bucket-destination"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3tables:PutTableData",
                "s3tables:GetTableData",
                "s3tables:UpdateTableMetadataLocation",
                "s3tables:PutTableMaintenanceConfiguration"
            ],
```

```
            "Resource": "arn:aws:s3tables:us-east-2:444455556666:bucket/amzn-s3-
demo-table-bucket-destination/table/*"
        }
    ]
}
```

4. Attach the permissions policy to the role:

```
aws iam put-role-policy \
    --role-name S3TablesReplicationRole \
    --policy-name S3TablesReplicationPermissions \
    --policy-document file://replication-permissions.json
```

> **Note**
>
> The permissions policy uses two resource scopes because the actions operate at different levels. `CreateTable` and `CreateNamespace` are bucket-level operations that create resources in the bucket, so they use the bucket ARN without `/table/*`. `PutTableData`, `GetTableData`, `UpdateTableMetadataLocation`, and `PutTableMaintenanceConfiguration` operate on existing tables, so they use the bucket ARN with `/table/*`.

5. (Optional) If using KMS encryption, add KMS permissions to your policy:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Condition": {
    "StringLike": {
      "kms:ViaService": [ "s3.us-east-1.amazonaws.com" ]
    },
    "ArnLike": {
      "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-bucket-source/table/*"
```

```
    }
  },
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Condition": {
    "StringLike": {
      "kms:ViaService": [ "s3.us-west-2.amazonaws.com" ]
    },
    "ArnLike": {
      "kms:EncryptionContext:aws:s3:arn": [ "arn:aws:s3tables:us-
west-2:444455556666:bucket/amzn-s3-demo-table-bucket-destination/table/*" ]
    }
  },
  "Resource": "*"
}
```

(Cross-account only) Step 2: Configure destination bucket policy

If you are replicating to a different AWS account, the destination account must grant permissions to the source account.

1. In the destination account, create a bucket policy for the destination table bucket. Save this as `destination-bucket-policy.json`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/S3TablesReplicationRole"
            },
            "Action": [
```

```
                "s3tables:PutTableData",
                "s3tables:GetTableData",
                "s3tables:UpdateTableMetadataLocation",
                "s3tables:PutTableMaintenanceConfiguration"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:444455556666:bucket/amzn-s3-
demo-table-bucket-cross-account-destination/table/*"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/S3TablesReplicationRole"
            },
            "Action": [
                "s3tables:CreateTable",
                "s3tables:CreateNamespace"
            ],
            "Resource": "arn:aws:s3tables:us-east-2:444455556666:bucket/amzn-s3-
demo-table-bucket-cross-account-destination"
        }
    ]
}
```

2. Apply the policy using the S3 Tables API:

```
aws s3tables put-table-bucket-policy \
    --table-bucket-arn arn:aws:s3tables:us-west-2:444455556666:bucket/amzn-s3-demo-
table-bucket-cross-account-destination \
    --resource-policy file://destination-bucket-policy.json \
    --profile destination-account
```

3. Modify your source KMS key to allow S3 Tables replication and maintenance:

```
{
  "Version": "2012-10-17",
  "Id": "key-consolepolicy-3",
  "Statement": [
        {
            "Sid": "allow replication to decrypt",
            "Effect": "Allow",
```

```
            "Principal": {
                "AWS": "replication_role_arn"
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/SOURCE-KEY-ID"
        },
        {
            "Sid": "allow maintenance",
            "Effect": "Allow",
            "Principal": {
                "Service": "maintenance.s3tables.amazonaws.com"
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/SOURCE-KEY-ID"
        }
  ]
}
```

4. Similarly, add permissions in your destination KMS key policy

```
{
    "Version": "2012-10-17",
    "Id": "key-policy-3",
    "Statement": [
        {
            "Sid": "allow maintenance",
            "Effect": "Allow",
            "Principal": {
                "Service": "maintenance.s3tables.amazonaws.com"
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-west-2:444455556666:key/DESTINATION-KEY-
ID-1"
        },
```

```
        {
            "Sid": "allow replication to encrypt/decrypt",
            "Effect": "Allow",
            "Principal": {
                "AWS": "replication_role_arn"
            },
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-west-2:444455556666:key/DESTINATION-KEY-
ID-1"
        }
    ]
}
```

Step 3: Create a replication configuration

You can use the AWS CLI to create a replication configuration at the table bucket-level or the table-level. For more information, see the following procedures.

Create a bucket-level replication configuration

Use this approach to replicate all tables in a bucket.

1. Create a replication configuration file. Save this as `bucket-replication-config.json`:

   Example: Single destination in same account

```
{
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",
  "rules": [
    {
      "destinations": [
        {
          "destinationTableBucketARN": "arn:aws:s3tables:us-
west-2:111122223333:bucket/amzn-s3-demo-table-bucket-dr"
        }
      ]
    }
  ]
```

```
}
```

Example: Multiple destinations across regions

```
{
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",
  "rules": [
    {
      "destinations": [
        {
          "destinationTableBucketARN": "arn:aws:s3tables:us-
west-2:111122223333:bucket/amzn-s3-demo-table-bucket-dr"
        },
        {
          "destinationTableBucketARN": "arn:aws:s3tables:eu-
west-1:111122223333:bucket/amzn-s3-demo-table-bucket-eu"
        },
        {
          "destinationTableBucketARN": "arn:aws:s3tables:ap-
south-1:111122223333:bucket/amzn-s3-demo-table-bucket-apac"
        }
      ]
    }
  ]
}
```

Example: Cross-account replication

```
{
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",
  "rules": [
    {
      "destinations": [
        {
          "destinationTableBucketARN": "arn:aws:s3tables:us-
east-1:444455556666:bucket/amzn-s3-demo-table-bucket-partner"
        }
      ]
```

```
    }
  ]
}
```

2. Apply the bucket-level replication configuration:

```
aws s3tables put-table-bucket-replication \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket \
    --configuration file://bucket-replication-config.json
```

Expected output:

```
{
  "versionToken": "3HL4kqtJl40Nr8X8gdRQBpUMLUo",
  "status": "Success"
}
```

Create a table-level replication configuration

Use this approach to replicate specific tables or to override bucket-level replication.

1. Create a replication configuration file. Save this as `table-replication-config.json`:

Example: Single table replication

```
{
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",
  "rules": [
    {
      "destinations": [
        {
          "destinationTableBucketARN": "arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket-analytics-bucket"
        }
```

```
      ]
    }
  ]
}
```

Example: Table with multiple destinations

```
{
  "role": "arn:aws:iam::111122223333:role/S3TablesReplicationRole",
  "rules": [
    {
      "destinations": [
        {
          "destinationTableBucketARN": "arn:aws:s3tables:us-
west-2:111122223333:bucket/amzn-s3-demo-table-bucket-dr"
        },
        {
          "destinationTableBucketARN": "arn:aws:s3tables:eu-
west-1:111122223333:bucket/amzn-s3-demo-table-bucket-eu"
        }
      ]
    }
  ]
}
```

2. Apply the table-level replication configuration:

```
aws s3tables put-table-replication \
    --table-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-
bucket/table/amzn-s3-demo-table-bucket-sales-data \
    --configuration file://table-replication-config.json
```

Expected output:

```
{
  "versionToken": "xT2LZkFZ0UuTC2h8XqtGLx2Ak6M",
```

```
  "status": "Success"
}
```

Managing S3 Tables replication

After you configure S3 Tables replication, you can monitor replica status to verify what's replicated. You can check replication status in the Amazon S3 console on the source table's **Management** tab, or by using the AWS CLI. For more information, see Setting up S3 Tables replication.This topic explains how to monitor replication and understand the different status values that indicate whether replication is completed, in progress, or has failed.

Monitoring replication status

Replication jobs run continuously for your replicated tables. You can query the status of replication with the GetTableReplicationStatus API or view it in the Amazon S3 console.

To get the status of replication by using the AWS CLI

The following example gets the replication status using the GetTableReplicationStatus API.

```
aws s3tables get-table-replication-status \
    --table-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket/table/sales-data
```

Expected output:

```
{
  "sourceTableARN": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket/table/sales-data",
  "destinations": [
    {
      "replicationStatus": "COMPLETED",
      "destinationBucketARN": "arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket",
      "destinationTableARN": "arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-table-bucket/table/sales-data",
```

```
      "lastSuccessfulReplicatedUpdate": {
        "metadataLocation": "latest_table_metadata.json",
        "timestamp": "2025-11-15T14:30:00Z"
      }
    },
    {
      "replicationStatus": "PENDING",
      "destinationBucketARN": "arn:aws:s3tables:eu-west-1:111122223333:bucket/amzn-s3-
demo-table-bucket-eu-bucket",
      "destinationTableARN": "arn:aws:s3tables:eu-west-1:111122223333:bucket/amzn-s3-
demo-table-bucket-eu-bucket/table/sales-data",
      "lastSuccessfulReplicatedUpdate": {
        "metadataLocation": "latest_table_metadata.json",
        "timestamp": "2025-11-15T14:25:00Z"
      }
    }
  ]
}
```

For more information, see get-table-replication-status in the *AWS CLI Command Reference*.

The following example shows a destination with a FAILED status, which includes a `failureMessage` field:

```
{
  "replicationStatus": "FAILED",
  "destinationBucketARN": "arn:aws:s3tables:eu-west-1:444455556666:bucket/amzn-s3-demo-
table-bucket-partner",
  "destinationTableARN": "arn:aws:s3tables:eu-west-1:444455556666:bucket/amzn-s3-demo-
table-bucket-partner/table/sales-data",
  "failureMessage": "Insufficient permissions given to successfully complete
 replication."
}
```

Note

The `get-table-replication` command returns the replication configuration (role, rules, and destinations). The `get-table-replication-status` command returns the

replication status (COMPLETED, PENDING, or FAILED), last replicated metadata, and error messages.

Understanding the response

The response contains the following elements:

- **sourceTableARN** – The ARN of the source table being replicated.
- **destinations** – An array of destination status objects, one for each configured replication destination. Each destination object contains:
  - **replicationStatus** – The current replication status for this destination (COMPLETED, PENDING, or FAILED).
  - **destinationBucketARN** – The ARN of the destination table bucket.
  - **destinationTableARN** – The ARN of the replica table in the destination bucket.
  - **lastSuccessfulReplicatedUpdate** – Information about the most recent successful replication:
    - **metadataLocation** – The Iceberg metadata file name that was last successfully replicated. Compare this with the source table's current metadata location to determine if replication is up to date.
    - **timestamp** – The time when this metadata file was replicated to the destination.
  - **failureMessage** (only present when status is FAILED) – A detailed error message describing why replication failed.

Replication status values

Replication can have three possible statuses for each destination:

- **COMPLETED** – All source table snapshots have been successfully replicated to the destination. The source table's latest metadata location matches the last replicated metadata location.
- **PENDING** – Replication is in progress or new commits are waiting to be replicated. The source table's latest metadata location differs from the last replicated metadata location.
- **FAILED** – The last replication job for this table failed. No new updates are being replicated.

If a destination shows a FAILED status, check the `failureMessage` field for details. Common causes include insufficient permissions, destination bucket not found, or KMS key issues. After you

fix the root cause, the service automatically retries replication. You can monitor recovery as the status transitions from FAILED to PENDING to COMPLETED.

S3 Tables AWS Regions, endpoints, and service quotas

The following sections include the supported AWS Regions and service quotas for S3 Tables.

Topics

- S3 Tables AWS Regions and endpoints
- S3 Tables quotas
- S3 Tables table migration quotas

S3 Tables AWS Regions and endpoints

For a list of Regions S3 Tables is currently available in, see Amazon S3 endpoints. To connect programmatically to an AWS service, you use an endpoint. For more information, see AWS service endpoints.

S3 Tables supports dual-stack endpoints for public access and AWS PrivateLink. Dual-stack endpoints allow you to access S3 tables buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol, depending on what your network supports.

S3 Tables dual-stack endpoints use the following naming convention: `s3tables.`*`aws-region`*`.api.aws`

For a complete list of S3 Tables endpoints, see Amazon S3 endpoints.

S3 Tables quotas

Quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. The following are the quotas for S3 Tables resources. For more Amazon S3 quota information, see Amazon S3 quotas.

Name	Default	Adjustable	Description
Table Buckets	100	To request a quota increase, contact Support.	The number of Amazon S3 table buckets that you

Name	Default	Adjustable	Description
			can create per AWS Region in an account.
Namespaces	10,000	To request a quota increase, contact Support.	The number of Amazon S3 table namespaces that you can create per table bucket.
Tables	10,000	To request a quota increase, contact Support.	The number of Amazon S3 tables that you can create per table bucket.

S3 Tables table migration quotas

The following are the quotas for S3 Tables table migration.

Name	Default	Adjustable	Description
Source objects per migration	1,000,000,000	No	The maximum number of objects in the source table that can be migrated in a single migration.
Column type nesting depth	20	No	The maximum nesting depth of column types, like a map of lists in the source table schema. Columns nested deeper than this limit are reported as unsupported in the

Name	Default	Adjustable	Description
			table compatibility report.
Partitions per source table	100,000	No	The maximum number of partitions in the source table that can be migrated.
Source object size	10 GiB	No	The maximum size of a single source object that can be migrated.
Concurrent migrations per account	10	No	The number of concurrent migrations allowed per account.
Concurrent migrations per destination table	1	No	The number of concurrent migrations allowed per destination table at any time.

Making requests to S3 Tables over IPv6

Amazon S3 supports the ability to access S3 buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol, using dual-stack endpoints. Dual-stack endpoints resolve to either an IPv6 endpoint or IPv4 endpoint depending on what your network supports.

The following are some things you should know before trying to access S3 Tables over IPv6:

- The client and the network accessing the table bucket must be enabled to use IPv6.
- Your tables client and your S3 client must both have dual-stack enabled.
- If you use IP address filtering IAM policies they must be updated to handle IPv6 addresses. For more information about managing access permissions with IAM, see the section called “Identity and Access Management (IAM)”.

- When using IPv6, server access log files output IP addresses in an IPv6 format. You need to update existing tools, scripts, and software that you use to parse Amazon S3 log files so that they can parse the IPv6 formatted `Remote IP` addresses. For more information, see the section called "Logging server access".

Getting started making S3 Tables requests over IPv6

When you make a request to a dual-stack endpoint, the table bucket URL resolves to an IPv6 or an IPv4 address depending on what your network supports. If your network prefers IPv4 requests will automatically use IPv4. If your network prefers IPv6, requests will use IPv6. No configuration change is required other than updating your client or application to enable the dual-stack endpoint.

When using the REST API, you directly access an Amazon S3 endpoint by using the endpoint name (URI). You can access S3 Tables and table buckets through a dual-stack endpoint using the following naming convention:

`s3tables.<region>.api.aws`

For a complete list of endpoints for S3 Tables, see Amazon Simple Storage Service endpoints and quotas.

When using the AWS CLI, AWS SDKs, and Iceberg clients, you can use a parameter or flag to change to a dual-stack endpoint. You can also specify the dual-stack endpoint directly as an override of the Amazon S3 endpoint in the config file.

You can enable dual-stack endpoint resolution in SDKs or clients by setting the dual-stack flag using the following command:

```
S3TablesClient client = S3TablesClient.builder()
    .region(Region.US_EAST_1)
    .dualstackEnabled(true)
    .build();
```

To use the dual-stack endpoint in the AWS CLI, see Using dual-stack endpoints from the AWS CLI.

For information on using the dual-stack endpoints for AWS PrivateLink, see, Using the dual-stack endpoints to access tables and table buckets.

Security for S3 Tables

Amazon S3 provides a variety of security features and tools. The following is a list of these features and tools supported by S3 Tables. Proper application of these tools can help ensure that your resources are protected and accessible only to the intended users.

Identity-based policies

Identity-based policies are attached to an IAM user, group, or role. You can use identity-based policies to grant an IAM identity access to your table buckets or tables. By default, users and roles don't have permission to create and modify tables and table buckets. They also can't perform tasks by using S3 console, AWS CLI, or Amazon S3 REST APIs. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to your resources. To create and access table buckets and tables, an IAM administrator must grant the necessary permissions to the AWS Identity and Access Management (IAM) role or users. For more information, see Access management for S3 Tables.

Resource-based policies

Resource-based policies are attached to a resource. You can create resource-based policies for table buckets and tables. You can use a table bucket policy to control table bucket and namespace-level API access permissions. You can also use a table bucket policy to control table-level API permissions on multiple tables in a bucket. Depending on the policy definition, the permissions attached to the bucket can apply to all or specific tables in the bucket. You can also use a table policy to grant table-level API access permissions to individual tables in the bucket.

When S3 Tables receives a request to perform a table bucket operation or a table operation, it first verifies that the requester has the necessary permissions. It evaluates all the relevant access policies, user policies, and resource-based policies in deciding whether to authorize the request (IAM user policy, IAM role policy, table bucket policy, and table policy). With table bucket policies and table policies, you can personalize access to your resources to ensure that only the identities you have approved can access your resources and perform actions on them. For more information, see Access management for S3 Tables.

AWS Organizations service control policies (SCPs) for S3 Tables.

You can use Amazon S3 Tables in Service Control Policies (SCPs) to manage permissions to users in your organization. Similar to IAM and resource policies, all table and bucket level actions are referenced as part of `s3tables` namespace in the policies. For more information, see Service control policies (SCPs) in the *AWS Organizations User Guide.*

Protecting S3 table data with encryption

Using server-side encryption with AWS KMS keys (SSE-KMS) in table buckets

Topics

- How SSE-KMS works for tables and table buckets
- Enforcing and scoping SSE-KMS use for tables and table buckets
- Monitoring and Auditing SSE-KMS encryption for tables and table buckets
- Permission requirements for S3 Tables SSE-KMS encryption
- Specifying server-side encryption with AWS KMS keys (SSE-KMS) in table buckets

Table buckets have a default encryption configuration that automatically encrypts tables by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all tables in your S3 table buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can configure your table buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). The security controls in AWS KMS can help you meet encryption-related compliance requirements. For more information about SSE-KMS, see Using server-side encryption with AWS KMS keys (SSE-KMS).

How SSE-KMS works for tables and table buckets

SSE-KMS with table buckets differs from SSE-KMS in general purpose buckets in the following ways:

- You can specify encryption settings for table buckets and individual tables.
- You can only use customer managed keys with SSE-KMS. AWS managed keys aren't supported.

- You must grant permissions for certain roles and AWS service principals to access your AWS KMS key. For more information, see Permission requirements for S3 Tables SSE-KMS encryption. This includes granting access to:
  - The S3 maintenance principal – for performing table maintenance on encrypted tables
  - Your S3 Tables integration role – for working with encrypted tables in AWS analytics services
  - Your client access role – for direct access to encrypted tables from Apache Iceberg clients
  - The S3 Metadata principal – for updating encrypted S3 metadata tables
- Encrypted tables use table-level keys that minimize the number of requests made to AWS KMS to make working with SSE-KMS encrypted tables more cost effective.

SSE-KMS encryption for table buckets

When you create a table bucket, you can choose SSE-KMS as the default encryption type and select a specific KMS key that will be used for encryption. Any tables created within that bucket will automatically inherit these encryption settings from their table bucket. You can use the AWS CLI, S3 API, or AWS SDKs to modify or remove the default encryption settings on a table bucket at any time. When you modify the encryption settings on a table bucket those settings apply only to new tables created in that bucket. Encryption settings for pre-existing tables are not changed. For more information, see Specifying encryption for table buckets.

SSE-KMS encryption for tables

You also have an option to encrypt an individual table with a different KMS key regardless of the bucket's default encryption configuration. To set encryption for an individual table, you must specify the desired encryption key at the time of table creation. If you want to change the encryption for an existing table, then you'll need to create a table with desired key and copy data from old table to the new one. For more information, see Specifying encryption for tables.

When using AWS KMS encryption, S3 Tables automatically creates unique table-level data keys that encrypt new objects associated with each table. These keys are used for a limited time period, minimizing the need for additional AWS KMS requests during encryption operations and reducing the cost of encryption. This is similar to S3 Bucket Keys for SSE-KMS.

Enforcing and scoping SSE-KMS use for tables and table buckets

You can use S3 Tables resource-based policies, KMS key policies, IAM identity-based policies, or any combination of these, to enforce the use of SSE-KMS for S3 tables and table buckets. For more

information on identity and resource polices for tables, see Access management for S3 Tables. For information on writing key policies, see Key policies in the *AWS Key Management Service Developer Guide*. The following examples show how you can use policies to enforce SSE-KMS.

Enforcing the use of SSE-KMS for all tables with a table bucket policy

This is an example of table bucket policy that prevents users from creating tables in a specific table bucket unless they encrypt tables with a specific AWS KMS key. To use this policy, replace the *`user input placeholders`* with your own information:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceKMSEncryptionAlgorithm",
      "Effect": "Deny",
      "Principal": "*",
      "Action": [
        "s3tables:CreateTable"
      ],
      "Resource": [
        "arn:aws:s3tables:us-west-2:111122223333:bucket/example-table-bucket/*"
      ],
      "Condition": {
        "StringNotEquals": {
          "s3tables:sseAlgorithm": "aws:kms"
        }
      }
    },
    {
      "Sid": "EnforceKMSEncryptionKey",
      "Effect": "Deny",
      "Principal": "*",
      "Action": [
        "s3tables:CreateTable"
      ],
      "Resource": [
        "arn:aws:s3tables:us-west-2:111122223333:bucket/example-table-bucket/*"
      ],
      "Condition": {
        "StringNotEquals": {
```

```
          "s3tables:kmsKeyArn": "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
        }
      }
    }
  ]
}
```

Requiring users to use SSE-KMS encryption with an IAM policy

This IAM identity policy requires users to use a specific AWS KMS key for encryption when creating or configuring S3 Tables resources. To use this policy, replace the *user input placeholders* with your own information:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RequireSSEKMSOnTables",
      "Action": [
          "s3tables:CreateTableBucket",
          "s3tables:PutTableBucketEncryption",
          "s3tables:CreateTable"
      ],
      "Effect": "Deny",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
            "s3tables:sseAlgorithm": "aws:kms"
        }
      }
    },
    {
      "Sid": "RequireKMSKeyOnTables",
      "Action": [
          "s3tables:CreateTableBucket",
          "s3tables:PutTableBucketEncryption",
          "s3tables:CreateTable"
      ],
      "Effect": "Deny",
      "Resource": "*",
      "Condition": {
```

```
        "StringNotEquals": {
            "s3tables:kmsKeyArn": "<key_arn>"
        }
      }
    }
  ]
}
```

Restricting the use of a key to a specific table bucket with a KMS key policy

This example KMS key policy allows the key to be used by a specific user only for encryption operations in a specific table bucket. This type of policy is useful for limiting access to a key in cross-account scenarios. To use this policy, replace the *user input placeholders* with your own information:

JSON

```
{
  "Version":"2012-10-17",
  "Id": "Id",
  "Statement": [
    {
      "Sid": "AllowPermissionsToKMS",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "kms:EncryptionContext:aws:s3:arn": "<table-bucket-arn>/*"
        }
      }
    }
  ]
}
```

Monitoring and Auditing SSE-KMS encryption for tables and table buckets

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your cryptographic operations, such as `GenerateDataKey` and `Decrypt`. CloudTrail supports numerous attribute values for filtering your search, including event name, user name, and event source.

You can track encryption configuration requests for Amazon S3 tables and table buckets by using CloudTrail events. The following API event names are used in CloudTrail logs:

- `s3tables:PutTableBucketEncryption`
- `s3tables:GetTableBucketEncryption`
- `s3tables:DeleteTableBucketEncryption`
- `s3tables:GetTableEncryption`
- `s3tables:CreateTable`
- `s3tables:CreateTableBucket`

> **Note**
>
> EventBridge isn't supported for table buckets.

Permission requirements for S3 Tables SSE-KMS encryption

When you use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) for tables in S3 table buckets you need to grant permissions for different identities in your account. At minimum your access identity and the S3 Tables maintenance principal need access to your key, the other permissions required depend on your use case.

Required Permissions

To access a table encrypted with a KMS key, you need these permissions on that key:

- `kms:GenerateDataKey`
- `kms:Decrypt`

> **Important**
>
> To use SSE-KMS on tables the Amazon S3 Tables maintenance service principal (`maintenance.s3tables.amazonaws.com`) needs `kms:GenerateDataKey` and `kms:Decrypt` permissions on the key.

Additional permissions

These additional permissions are required depending on your use case:

- **Permissions for AWS analytics services and direct access** – If you work with SSE-KMS encrypted tables through AWS analytics services or third-party engines accessing S3 tables directly, the IAM role you use needs permission to use your KMS key.
- **Permissions with Lake Formation enabled** – If you have opted in to AWS Lake Formation for access control, the Lake Formation service role needs permission to use your KMS key.
- **Permissions for S3 Metadata tables** – If you use SSE-KMS encryption for S3 Metadata tables, you need to provide the S3 Metadata service principal (`metadata.s3.amazonaws.com`) access to your KMS key. This allows S3 Metadata to update encrypted tables so they will reflect your latest data changes.

> **Note**
>
> For cross-account KMS keys, your IAM role needs both key access permission and explicit authorization in the key policy. For more information about cross-account permissions for KMS keys, see Allowing external AWS accounts to use a KMS key in the *AWS Key Management Service Service Developer Guide*.

Topics

- Granting the S3 Tables maintenance service principal permissions to your KMS key
- Granting IAM principals permissions to work with encrypted tables in integrated AWS analytics services
- Granting IAM principals permissions to work with encrypted tables when Lake Formation is enabled
- Granting the S3 Metadata service principal permissions to use your KMS key

Granting the S3 Tables maintenance service principal permissions to your KMS key

This permission is required to create SSE-KMS encrypted tables and to allow automatic table maintenance like compaction, snapshot management, and unreferenced file removal on the encrypted tables.

> **Note**
>
> Whenever you make a request to create an SSE-KMS encrypted table, S3 Tables checks to make sure the `maintenance.s3tables.amazonaws.com` principal has access to your KMS key. To perform this check, a zero-byte object is temporarily created in your table bucket, this object will be automatically removed by the unreferenced file removal maintenance operations. If the KMS key you specified for encryption doesn't have maintenance access the createTable operation will fail.

To grant maintenance access on SSE-KMS encrypted tables, you can use the following example key policy. In this policy, the `maintenance.s3tables.amazonaws.com` service principal is granted permission to use a specific KMS key for encrypting and decrypting tables in a specific table bucket. To use the policy, replace the *`user input placeholders`* with your own information:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "EnableKeyUsage",
            "Effect": "Allow",
            "Principal": {
                "Service": "maintenance.s3tables.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id",
            "Condition": {
                "StringLike": {
```

```
                    "kms:EncryptionContext:aws:s3:arn":"<table-or-table-bucket-
arn>/*"
                }
            }
        }
    ]
}
```

Granting IAM principals permissions to work with encrypted tables in integrated AWS analytics services

To work with S3 tables in AWS analytics services, you integrate your table buckets with AWS Glue Data Catalog. This integration allows AWS analytics services to automatically discover and access table data. For more information on the integration, see Integrating Amazon S3 Tables with AWS analytics services.

When you work with SSE-KMS encrypted tables through AWS analytics services or third-party and open-source engines accessing S3 tables directly, the IAM role you use needs permission to use your AWS KMS key for encryption operations.

You can grant KMS key access through an IAM policy attached to your role or through a KMS key policy.

IAM policy

Attach this inline policy to the IAM role you use for querying to allow KMS key access. Replace the KMS key ARN with your own.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowKMSKeyUsage",
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
        }
```

```
    ]
}
```

KMS key policy

Alternatively, attach this statement to your KMS key policy to allow the specified IAM role to use the key. Replace the role ARN with the IAM role you use for querying.

```
{
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::<catalog-account-id>:role/<role-name>"
        ]
    },
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey",
    ],
    "Resource": "*"
}
```

Granting IAM principals permissions to work with encrypted tables when Lake Formation is enabled

If you have opted in to AWS Lake Formation for access control on your S3 Tables integration, the Lake Formation service role needs permission to use your AWS KMS key for encryption operations. Lake Formation uses this role to vend credentials on behalf of principals accessing your tables.

The following KMS key policy example grants the Lake Formation service role permission to use a specific KMS key in your account for encryption operations. Replace the placeholder values with your own.

```
{
  "Sid": "AllowTableRoleAccess",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/service-role/S3TablesRoleForLakeFormation"
  },
  "Action": [
```

```
      "kms:GenerateDataKey",
      "kms:Decrypt"
  ],
  "Resource": "<kms-key-arn>"
}
```

Granting the S3 Metadata service principal permissions to use your KMS key

To allow Amazon S3 to update SSE-KMS encrypted metadata tables, and perform maintenance on those metadata tables, you can use the following example key policy. In this policy, you allow the `metadata.s3.amazonaws.com` and `maintenance.s3tables.amazonaws.com` service principals to encrypt and decrypt tables in a specific table bucket using a specific key. To use the policy, replace the *`user input placeholders`* with your own information:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "EnableKeyUsage",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "maintenance.s3tables.amazonaws.com",
                    "metadata.s3.amazonaws.com"
                ]
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
            "Condition": {
                "StringLike": {
                    "kms:EncryptionContext:aws:s3:arn":"<table-or-table-bucket-
arn>/*"
                }
            }
        }
    ]
```

```
}
```

Specifying server-side encryption with AWS KMS keys (SSE-KMS) in table buckets

All Amazon S3 table buckets have encryption configured by default, and all new tables created in an table bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every table bucket. If you want to specify a different encryption type, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

You can specify SSE-KMS encryption in your `CreateTableBucket` or `CreateTable` requests, or you can set the default encryption configuration in the table bucket in a `PutTableBucketEncryption` request.

> **Important**
>
> To allow automatic maintenance on SSE-KMS encrypted tables and table buckets you must grant the maintenance.s3tables.amazonaws.com service principal permission to use your KMS key. For more information, see Permission requirements for S3 Tables SSE-KMS encryption.

Specifying encryption for table buckets

You can specify SSE-KMS as the default encryption type when you create a new table bucket, for examples, see Creating a table bucket. After creating a table bucket, you can specify the use of SSE-KMS as the default encryption setting using REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI).

> **Note**
>
> When you specify SSE-KMS as the default encryption type, the key you use for encryption must allow access to the S3 Tables maintenance service principal. If the maintenance service principal does not have access, you will be unable to create tables in that table bucket. For more information, see Granting the S3 Tables maintenance service principal permissions to your KMS key.

Using the AWS CLI

To use the following example AWS CLI command, replace the *user input placeholders* with your own information.

```
aws s3tables put-table-bucket-encryption \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket; \
    --encryption-configuration '{
        "sseAlgorithm": "aws:kms",
        "kmsKeyArn": "arn:aws:kms:us-east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }' \
    --region us-east-1
```

You can remove the default encryption setting for a table bucket using the DeleteTableBucketEncryption API operation. When you remove encryption settings new tables created in the table bucket will use the default SSE-S3 encryption.

Specifying encryption for tables

You can apply SSE-KMS encryption to a new table when you create it using query engines, REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI). The encryption settings you specify when creating a table take precedence over the default encryption setting of the table bucket.

> **Note**
>
> When you use SSE-KMS encryption for a table the key you use for encryption must allow the S3 Tables maintenance service principal to access it. If the maintenance service principal does not have access, you will be unable to create the table. For more information, see Granting the S3 Tables maintenance service principal permissions to your KMS key.

Required permissions

The following permissions are required to create encrypted tables

- `s3tables:CreateTable`

- `s3tables:PutTableEncryption`

Using the AWS CLI

The following AWS CLI example creates a new table with a basic schema, and encrypts it with a customer managed AWS KMS key. To use the command, replace the *`user input placeholders`* with your own information.

```
aws s3tables create-table \
  --table-bucket-arn "arn:aws:s3tables:Region:ownerAccountId:bucket/amzn-s3-demo-table-bucket" \
  --namespace "mydataset" \
  --name "orders" \
  --format "ICEBERG" \
  --encryption-configuration '{
    "sseAlgorithm": "aws:kms",
    "kmsKeyArn":
 "arn:aws:kms:Region:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
  }' \
  --metadata '{
    "iceberg": {
      "schema": {
        "fields": [
          {
            "name": "order_id",
            "type": "string",
            "required": true
          },
          {
            "name": "order_date",
            "type": "timestamp",
            "required": true
          },
          {
            "name": "total_amount",
            "type": "decimal(10,2)",
            "required": true
          }
        ]
      }
    }
  }'
```

Data protection refers to protecting data while it's in transit (as it travels to and from Amazon S3) and at rest (while it's stored on disks in Amazon S3 data centers). S3 Tables always protects data in transit using Transport Layer Security (1.2 and above) through HTTPS. For protecting data at rest in S3 table buckets, you have the following options:

Server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 table buckets have encryption configured by default. The default option for server-side encryption is with Amazon S3 managed keys (SSE-S3). This encryption comes at no cost to you and applies to all tables in your S3 table buckets unless you specify another form of encryption. Each object is encrypted with a unique key. As an additional safeguard, SSE-S3 encrypts the key itself with a root key that it regularly rotates. SSE-S3 uses one of the strongest block ciphers available, 256-bit Advanced Encryption Standard (AES-256), to encrypt your data.

Server-side encryption with AWS KMS keys (SSE-KMS)

You can choose to configure table buckets or tables to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). The security controls in AWS KMS can help you meet encryption-related compliance requirements. SSE-KMS gives you more control over your encryption keys by allowing you to do the following:

- Create, view, edit, monitor, enable or disable, rotate, and schedule deletion of KMS keys.
- Define the policies that control how and by whom KMS keys can be used.
- Track key usage in AWS CloudTrail to verify your KMS keys are being used correctly.

S3 Tables supports using customer managed keys in SSE-KMS to encrypt tables. AWS managed keys are not supported. For more information on using SSE-KMS for S3 tables and table buckets, see Using server-side encryption with AWS KMS keys (SSE-KMS) in table buckets.

Access management for S3 Tables

In S3 Tables resources include table buckets and the tables that they contain. The root user of the AWS account that created the resource (the resource owner) and AWS Identity and Access Management (IAM) users within that account that have the necessary permissions can access a resource that they created. The resource owner specifies who else can access the resource and the actions that they are allowed to perform on the resource. Amazon S3 has various access management tools that you can use to grant others access to your S3 resources. If you've integrated your tables with AWS Lake Formation, then you can also manage fine-grained access to your tables and namespaces. The following topics provide you with an overview of resources, IAM

actions, and condition keys for S3 Tables. They also provide examples for both resource-based and identity-based policies for S3 Tables.

Topics

- Resources
- Actions for S3 Tables
- Condition keys for S3 Tables
- IAM identity-based policies for S3 Tables
- Resource-based policies for S3 Tables
- AWS managed policies for S3 Tables
- Granting access with SQL semantics
- Managing access to a table or database with Lake Formation

Resources

S3 Tables resources include table buckets and the tables that they contain.

- Table buckets – Table buckets are specifically designed for tables and provider higher transactions per seconds (TPS) and better query throughput compared to self-managed tables in general purpose S3 buckets. Table buckets deliver the same durability, availability, scalability, and performance characteristics as Amazon S3 general purpose buckets.
- Tables – Tables in your table buckets are stored in Apache Iceberg format. You can query these tables using standard SQL in query engines that support Iceberg.

Amazon Resource Names (ARNs) for tables and table buckets contain the `s3tables` namespace, the AWS Region, the AWS account ID, and the bucket name. To access and perform actions on your tables and table buckets, you must use the following ARN formats:

- Table ARN format:

```
arn:aws:s3tables:us-west-2:111122223333:bucket/amzn-s3-demo-bucket/
table/demo-tableID
```

Actions for S3 Tables

In an identity-based policy or resource-based policy, you define which S3 Tables actions are allowed or denied for specific IAM principals. Tables actions correspond to bucket and table-level API operations. All actions are part of a unique IAM namespace: `s3tables`.

When you use an action in a policy, you usually allow or deny access to the API operation with the same name. However, in some cases, a single action controls access to more than one API operation. For example, the `s3tables:GetTableData` actions includes permissions for the `GetObject`, `ListParts`, and `ListMultiparts` API operations.

The following are supported actions for table buckets. You can specify the following actions in the `Action` element of an IAM policy or resource policy.

Action	Description	Access level	Cross-account access
`s3tables:CreateTableBucket`	Grants permissions to create a table bucket	`Write`	No
`s3tables:GetTableBucket`	Grants permission to retrieve a table bucket ARN, table bucket name, and create date.	`Write`	Yes
`s3tables:ListTableBuckets`	Grants permission to list all table buckets in this account.	`Read`	No

Action	Description	Access level	Cross-account access
s3tables:CreateNamespace	Grants permission to create a name space in a table bucket	Write	Yes
s3tables:GetNamespace	Grants permission to retrieve namespace details	Read	Yes
s3tables:ListNamespaces	Grants permission to list all namespaces on the table bucket.	Read	Yes
s3tables:DeleteNamespace	Grants permission to delete a namespace in a table bucket	Write	Yes
s3tables:DeleteTableBucket	Grants permission to delete the bucket	Write	Yes

Action	Description	Access level	Cross-account access
s3tables:PutTableBucketPolicy	Grants permission to add or replace a bucket policy	Permissions Management	No
s3tables:GetTableBucketPolicy	Grants permission to retrieve the bucket policy	Read	No
s3tables:DeleteTableBucketPolicy	Grants permission to delete the bucket policy	Permissions Management	No
s3tables:GetTableBucketMaintenanceConfiguration	Grants permission to retrieve the maintenance configuration for a table bucket	Read	Yes
s3tables:PutTableBucketMaintenanceConfiguration	Grants permission to add or replace the maintenance configuration for a table bucket	Write	Yes

Action	Description	Access level	Cross-account access
s3tables:PutTableBucketEncryption	Grants permission to add or replace the encryption configuration for a table bucket	Write	No
s3tables:GetTableBucketEncryption	Grants permission to retrieve the encryption configuration for a table bucket	Read	No
s3tables:DeleteTableBucketEncryption	Grants permission to delete the encryption configuration for a table bucket	Write	No

The following actions are supported for tables:

Action	Description	Access level	Cross-account access
s3tables:GetTableMaintenanc	Grants permission to retrieve the maintenance	Read	Yes

Action	Description	Access level	Cross-account access
eConfigur ation	configuration for a table		
s3tables: PutTableM aintenanc eConfigur ation	Grants permissio n to add or replace the maintenance configuration for a table	Write	Yes
s3tables: PutTableP olicy	Grants permissio n to add or replace a table policy	Permissions Management	No
s3tables: GetTableP olicy	Grants permission to retrieve the table policy	Read	No
s3tables: DeleteTab lePolicy	Grants permission to delete the table policy	Permissions management	No
s3tables: CreateTable	Grants permissio n to create a table in a table bucket	Write	Yes

Action	Description	Access level	Cross-account access
s3tables:GetTable	Grants permission to retrieve a table information	Read	Yes
s3tables:GetTableMetadataLocation	Grants permission to retrieve the table root pointer (metadata file)	Read	Yes
s3tables:ListTables	Grants permission to list all tables in a table bucket	Read	Yes
s3tables:RenameTable	Grant permissions to change the name of a table.	Write	Yes
s3tables:UpdateTableMetadataLocation	Grants permission to update table root pointer (metadata file)	Write	Yes

Action	Description	Access level	Cross-account access
s3tables:GetTableData	Grants permission to read the table metadata and data objects stored in the table bucket	Read	Yes
s3tables:PutTableData	Grants permission to write the table metadata and data objects stored in the table bucket	Write	Yes
s3tables:GetTableEncryption	Grants permission to retrieve the encryption settings for a table	Write	No
s3tables:PutTableEncryption	Grants permission to add encryption to a table	Write	No

Action	Description	Access level	Cross-account access
s3tables:DeleteTable	Grants permission to delete a table from a table bucket	Write	Yes

To perform table-level read and write actions, S3 Tables supports Amazon S3 API operations such as GetObject and PutObject. The following table provides a list of object-level actions. When granting read and write permissions to your tables, you use the following actions.

Action	S3 object APIs		
s3tables:GetTableData	GetObject, ListParts, HeadObject		
s3tables:PutTableData	PutObject, CreateMultipartUpload, CompleteMultipartUpload, UploadPart, AbortMultipartUpload		

For example, if a user has `GetTableData` permissions, then they can read all the files associated with the table, such as its metadata file, manifest, manifest list files, and parquet data files.

Condition keys for S3 Tables

S3 Tables supports AWS global condition context keys.

Additionally, S3 Tables defines the following condition keys that you can use in an access policy.

Condition key	Description	Type	
`s3tables:tableName`	Filters access by the name of the tables in the table bucket. You can use the `s3tables:tableName` condition key to write IAM, or table bucket policies that restrict user or application access to only the tables that meet this name condition. It's important to note that if you use the	`String`	

Condition key	Description	Type	
	`s3tables:tableName` condition key to control access then changes in tables' name could impact these policies. **Example value:** `"s3tables:tableName":"department*"`		

Condition key	Description	Type	
`s3tables:namespace`	Filters access by the namespaces created in the table bucket. You can use the `s3tables:namespace` condition key to write IAM, table, or table bucket policies that restrict user or application access to tables that are part of a specific namespace. *Example value:* `"s3tables:namespace":"hr"` It's important to note that if you use the `s3tables:namespace` condition	`String`	

Condition key	Description	Type	
	key to control access, then changes in namespaces could impact these policies.		

Condition key	Description	Type	
`s3tables:SSEAlgorithm`	Filters access by the server-side encryption algorithm used to encrypt a table. You can use the `s3tables:SSEAlgorithm` condition key to write IAM, table, or table bucket policies that restrict user or application access to tables that are encrypted with a certain encryption type. *Example value:* `"s3tables:SSEAlgorithm":"aws:kms"`	`String`	

Condition key	Description	Type	
	It's important to note that if you use the `s3tables:SSEAlgorithm` condition key to control access, then changes in encryption could impact these policies.		

Condition key	Description	Type	
`s3tables:KMSKeyArn`	Filters access by the AWS KMS key ARN for the key used to encrypt a table You can use the `s3tables:KMSKeyArn` condition key to write IAM, table, or table bucket policies that restrict user or application access to tables that are encrypted with a specific KMS key. It's important to note that if you use the `s3tables:KMSKeyArn` condition key to control	ARN	

Condition key	Description	Type	
	access, then changing your KMS key could impact these policies.		

IAM identity-based policies for S3 Tables

By default, users and roles don't have permission to create or modify tables and table buckets. They also can't perform tasks by using the s3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST APIs. To create and access table buckets and tables, an AWS Identity and Access Management (IAM) administrator must grant the necessary permissions to the IAM role or users. To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Creating IAM policies in the *IAM User Guide*.

The following topic includes examples of IAM identity-based policies. To use the following example policies, replace the *`user input placeholders`* with your own information.

Topics

- Example 1: Allow access to create and use table buckets
- Example 2: Allow access to create and use tables in a table bucket

Example 1: Allow access to create and use table buckets

.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowBucketActions",
            "Effect": "Allow",
            "Action": [
```

```
                "s3tables:CreateTableBucket",
                "s3tables:PutTableBucketPolicy",
                "s3tables:GetTableBucketPolicy",
                "s3tables:ListTableBuckets",
                "s3tables:GetTableBucket"
            ],
            "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/*"
        }
    ]
}
```

Example 2: Allow access to create and use tables in a table bucket

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowBucketActions",
            "Effect": "Allow",
            "Action": [
                "s3tables:GetTableBucket",
                "s3tables:ListTables",
                "s3tables:CreateTable",
                "s3tables:PutTableData",
                "s3tables:GetTableData",
                "s3tables:GetTable",
                "s3tables:GetTableMetadataLocation",
                "s3tables:UpdateTableMetadataLocation",
                "s3tables:GetNamespace",
                "s3tables:CreateNamespace",
                "s3tables:ListNamespaces"
            ],
            "Resource": [
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket",
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket/table/*"
            ]
        }
    ]
```

```
}
```

Resource-based policies for S3 Tables

S3 Tables provides resource-based policies for managing access to table buckets and tables: table bucket policies and table policies. You can use a table bucket policy to grant API access permissions at the table bucket, namespace, or table-level. The permissions attached to the table bucket can apply to all tables in the bucket or to specific tables in the bucket, depending on the policy definition. You can use a table policy to grant permissions at the table-level.

When S3 Tables receives a request, it first verifies that the requester has the necessary permissions. It evaluates all the relevant access policies, user policies, and resource-based policies in deciding whether to authorize the request (IAM user policy, IAM role policy, table bucket policy, and table policy). For example, if a table bucket policy grants a user permissions to perform all actions on the tables in the bucket (including `DeleteTable`), but an individual table has a table policy that denies the `DeleteTable` action for all users, then the user cannot delete the table.

The following topic includes examples of table and table bucket policies. To use these policies, replace the *`user input placeholders`* with your own information.

Note

- Every policy that grants permissions to modify tables should include permissions for `GetTableMetadataLocation` to access the table root file. For more information, see `GetTableMetadataLocation`.
- Every time that you perform a write or delete activity on your table, include permissions to `UpdateTableMetadataLocation` in your access policy.
- We recommend using a table bucket policy for governing access to bucket-level actions and a table policy for governing access to table-level actions. In cases where you want to define the same set of permissions across multiple tables, then we recommend using a table bucket policy.

Topics

- Example 1: Table bucket policy allows access to PutBucketMaintenanceConfiguration for buckets in an account

- Example 2: Table bucket policy to allows read (SELECT) access to tables stored in the hrnamespace
- Example 3: Table policy to allow user to delete a table

Example 1: Table bucket policy allows access to PutBucketMaintenanceConfiguration for buckets in an account

The following example table bucket policy allows the IAM `data steward` to delete unreferenced objects for all the buckets in an account by allowing access to `PutBucketMaintenanceConfiguration`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/datasteward"
            },
            "Action": [
                "s3tables:PutTableBucketMaintenanceConfiguration"
            ],
            "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/*"
        }
    ]
}
```

Example 2: Table bucket policy to allows read (SELECT) access to tables stored in the hrnamespace

The following an example table bucket policy allows Jane, a user from AWS account ID `123456789012` to access tables stored in the `hr` namespace in a table bucket.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Jane"
            },
            "Action": [
                "s3tables:GetTableData",
                "s3tables:GetTableMetadataLocation"
            ],
            "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-
demo-table-bucket/table/*",
            "Condition": {
                "StringLike": {
                    "s3tables:namespace": "hr"
                }
            }
        }
    ]
}
```

Example 3: Table policy to allow user to delete a table

The following example table policy that allows the IAM role `data steward` to delete a table.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "DeleteTable",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/datasteward"
            },
            "Action": [
                "s3tables:DeleteTable",
                "s3tables:UpdateTableMetadataLocation",
                "s3tables:PutTableData",
                "s3tables:GetTableMetadataLocation"
```

```
            ],
            "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-
demo-bucket/table/tableUUID"
        }
    ]
}
```

AWS managed policies for S3 Tables

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: AmazonS3TablesFullAccess

You can attach the `AmazonS3TablesFullAccess` policy to your IAM identities. This policy grants permissions that allow full access to Amazon S3 Tables. For more information about this policy, see AmazonS3TablesFullAccess.

AWS managed policy: AmazonS3TablesReadOnlyAccess

You can attach the `AmazonS3TablesReadOnlyAccess` policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon S3 Tables. For more information about this policy, see AmazonS3TablesReadOnlyAccess.

AWS managed policy: AmazonS3TablesLakeFormationServiceRole

You can attach the `AmazonS3TablesLakeFormationServiceRole` policy to your IAM identities. This policy grants permissions that allow the AWS Lake Formation service role access to S3 Tables. AWS KMS permissions are used to allow Lake Formation to access encrypted tables. For more information about this policy, see AmazonS3TablesLakeFormationServiceRole.

Amazon S3 Tables updates to AWS managed policies

View details about updates to AWS managed policies for Amazon S3 Tables since S3 Tables began tracking these changes.

Change	Description	Date
Amazon S3 Tables updated `AmazonS3TablesFullAccess` .	S3 Tables updated the AWS-managed policy called `AmazonS3TablesFullAccess` . This update grants permission to pass a role to the S3 Tables Replication service.	December 2, 2025
Amazon S3 Tables added `AmazonS3TablesLakeFormationServiceRole` .	S3 Tables added a new AWS-managed policy called `AmazonS3TablesLakeFormationServiceRole` . This policy grants permissions that allows the Lake Formation service role access to S3 Tables.	May 19, 2025
Amazon S3 Tables added `AmazonS3TablesFullAccess` .	S3 Tables added a new AWS-managed policy called `AmazonS3TablesFullAccess` . This policy grants permissions that allow full access to Amazon S3 Tables.	December 03, 2024

Change	Description	Date
Amazon S3 Tables added `AmazonS3TablesReadOnlyAccess` .	S3 Tables added a new AWS-managed policy called `AmazonS3TablesReadOnlyAccess` . This policy grants permissions to allow read-only access to Amazon S3 Tables.	December 03, 2024
Amazon S3 Tables started tracking changes.	Amazon S3 Tables started tracking changes for its AWS managed policies.	December 03, 2024

Granting access with SQL semantics

You can grant permissions to tables by using SQL semantics in table and table bucket policies. Examples of SQL semantics you can use are `CREATE`, `INSERT`, `DELETE`, `UPDATE`, and `ALTER`. The following table provides a list of API actions associated with SQL semantics that you can use to grant permissions to your users.

S3 Tables partially supports permissions using SQL semantics. For example, the `CreateTable` API only creates an empty table in the table bucket. You need additional permissions such as, `UpdateTableMetadata`, `PutTableData`, and `GetTableMetadataLocation` to be able to set the table schema. These additional permissions also mean that you are also granting the user access to insert rows in the table. If you wish to govern access purely based on SQL semantics, then we recommend using AWS Lake Formation or any third-party solution that is integrated with S3 Tables.

Table-level activity	IAM actions		
`SELECT`	`s3tables:GetTableData` , `s3tables:GetTableM`		

Table-level activity	IAM actions		
	etadataLocation		
CREATE	s3tables:CreateTable , s3tables:UpdateTableMetadataLocation , s3tables:PutTableData , s3tables:GetTableMetadataLocation ,		
INSERT	s3tables:UpdateTableMetadataLocation , s3tables:PutTableData , s3tables:GetTableMetadataLocation		

Table-level activity	IAM actions		
UPDATE	s3tables:UpdateTableMetadataLocation , s3tables:PutTableData , s3tables:GetTableMetadataLocation		
ALTER,RENAME	s3tables:UpdateTableMetadataLocation , s3tables:PutTableData , s3tables:GetTableMetadataLocation , s3tables:RenameTable		

Table-level activity	IAM actions		
DELETE,DROP	s3tables:DeleteTable , s3tables:UpdateTableMetadataLocation , s3tables:PutTableData , s3tables:GetTableMetadataLocation		

> **Note**
>
> The `s3tables:DeleteTable` permission is required to delete a table from a table bucket. This permission allows you to permanently remove a table and all its associated data and metadata. Use this permission carefully as the delete operation cannot be undone.

Managing access to a table or database with Lake Formation

If your table buckets are integrated with the AWS analytics service using Lake Formation, then Lake Formation manages access to your tables and requires that each IAM principal (user or role) be authorized to perform actions them. Lake Formation uses its own permissions model (Lake Formation permissions) that enables fine-grained access control for Data Catalog resources.

For more information, see Overview of Lake Formation permissions in the *AWS Lake Formation Developer Guide*.

There are two main types of permissions in AWS Lake Formation:

1. Metadata access permissions control the ability to create, read, update, and delete metadata databases and tables in the Data Catalog.
2. Underlying data access permissions control the ability to read and write data to the underlying Amazon S3 locations that the Data Catalog resources point to.

Lake Formation uses a combination of its own permissions model and the IAM permissions model to control access to Data Catalog resources and underlying data:

- For a request to access Data Catalog resources or underlying data to succeed, the request must pass permission checks by both IAM and Lake Formation.
- IAM permissions control access to the Lake Formation and AWS Glue APIs and resources, whereas Lake Formation permissions control access to the Data Catalog resources, Amazon S3 locations, and the underlying data.

Lake Formation permissions apply only in the Region in which they were granted, and a principal must be authorized by a data lake administrator or another principal with the necessary permissions in order to be granted Lake Formation permissions.

Note

If you're the user who performed the table bucket integration, you already have Lake Formation permissions to your tables. If you're the only principal who will access your tables, you can skip this step. You only need to grant Lake Formation permissions on your tables to other IAM principals. This allows other principals to access the table when running queries. For more information, see Granting Lake Formation permission on a table or database.

Granting Lake Formation permission on a table or database

You can grant a principal Lake Formation permissions on a table or database in a table bucket, either through the Lake Formation console or the AWS CLI.

Note

When you grant Lake Formation permissions on a Data Catalog resource to an external account or directly to an IAM principal in another account, Lake Formation uses the

AWS Resource Access Manager (AWS RAM) service to share the resource. If the grantee account is in the same organization as the grantor account, the shared resource is available immediately to the grantee. If the grantee account is not in the same organization, AWS RAM sends an invitation to the grantee account to accept or reject the resource grant. Then, to make the shared resource available, the data lake administrator in the grantee account must use the AWS RAM console or AWS CLI to accept the invitation. For more information about cross-account data sharing, see Cross-account data sharing in Lake Formation in the *AWS Lake Formation Developer Guide*.

Console

1. Open the AWS Lake Formation console at https://console.aws.amazon.com/lakeformation/, and sign in as a data lake administrator. For more information about how to create a data lake administrator, see Create a data lake administrator in the *AWS Lake Formation Developer Guide*.
2. In the navigation pane, choose **Data permissions**, and then choose **Grant**.
3. On the **Grant Permissions** page, under **Principals**, do one of the following:
   - For Amazon Athena or Amazon Redshift, choose **IAM users and roles**, and select the IAM principal you use for queries.
   - For Amazon Data Firehose, choose **IAM users and roles**, and select the service role that you created to stream to tables.
   - For Quick, choose **SAML users and groups**, and enter the Amazon Resource Name (ARN) of your Quick admin user.
   - For AWS Glue Iceberg REST endpoint access, choose **IAM users and roles** then select the IAM role you created for you client. For more information, see Create an IAM role for your client
4. Under **LF-Tags or catalog resources**, choose **Named Data Catalog resources**.
5. For **Catalogs**, choose the subcatalog that you created when you integrated your table bucket, for example, *`account-id`*`:s3tablescatalog/`*`amzn-s3-demo-bucket`*.
6. For **Databases**, choose the S3 table bucket namespace that you created.
7. (Optional) For **Tables**, choose the S3 table that you created in your table bucket.

> **Note**
>
> If you're creating a new table in the Athena query editor, don't select a table.

8. Do one of the following:
   - If you specified a table in the prior step, for **Table permissions**, choose **Super**.
   - If you didn't specify a table in the prior step, go to **Database permissions**. For cross-account data sharing, you can't choose **Super** to grant the other principal all permissions on your database. Instead, choose more fine-grained permissions, such as **Describe**.
9. Choose **Grant**.

CLI

1. Make sure that you're running the following AWS CLI commands as a data lake administrator. For more information, see Create a data lake administrator in the *AWS Lake Formation Developer Guide*.
2. Run the following command to grant Lake Formation permissions on table in S3 table bucket to an IAM principal to access the table. To use this example, replace the *`user input placeholders`* with your own information.

```
aws lakeformation grant-permissions \
--region us-east-1 \
--cli-input-json \
'{
    "Principal": {
        "DataLakePrincipalIdentifier": "user or role ARN, for example,
 arn:aws:iam::account-id:role/example-role"
    },
    "Resource": {
        "Table": {
            "CatalogId": "account-id:s3tablescatalog/amzn-s3-demo-bucket",
            "DatabaseName": "S3 table bucket namespace, for example,
 test_namespace",
            "Name": "S3 table bucket table name, for example test_table"
        }
    },
    "Permissions": [
```

```
        "ALL"
    ]
}'
```

VPC connectivity for S3 Tables

All tables in S3 Tables are in the Apache Iceberg format and are made up of two types of S3 objects. These two types of objects are data files which store the data and metadata files which track information about the data files at different points in time. All table bucket, namespace, and table operations (for example, `CreateNamespace`, `CreateTable`, and so on) are routed through an S3 Tables endpoint (`s3tables.region.amazonaws.com`) and all object-level operations that read or write the data and metadata files continue to be routed through an S3 service endpoint (`s3.region.amazonaws.com`).

To access S3 Tables, Amazon S3 supports two types of VPC endpoints by using AWS PrivateLink: gateway endpoints and interface endpoints. A gateway endpoint is a gateway that you specify in your route table to access S3 from your VPC over the AWS network. Interface endpoints extend the functionality of gateway endpoints by using private IP addresses to route requests to Amazon S3 from within your VPC, on premises, or from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway.

To access S3 Tables from a VPC, we recommend creating two VPC endpoints (one for S3 and the other for S3 Tables). You can create either a gateway or an interface endpoint to route file (object) level operations to S3 and an interface endpoint to route bucket and table-level operations to S3 Tables. You can create and use VPC endpoints for file-level requests using S3. For more information, see Gateway endpoints in the *AWS PrivateLink* User Guide.

To learn more about using AWS PrivateLink to create and work with endpoints for S3 Tables, see the following topics. To create a VPC interface endpoint, see Create a VPC endpoint in the *AWS PrivateLink Guide*.

Topics

- Creating VPC endpoints for S3 Tables
- Accessing table buckets and tables through endpoints using the AWS CLI
- Configuring a VPC network when using query engines
- Using the dual-stack endpoints to access tables and table buckets
- Using VPC endpoint policy conditions with table bucket policies

- Restricting access to S3 Tables within the VPC network

Creating VPC endpoints for S3 Tables

When you create a VPC endpoint, S3 Tables generates two types of endpoint-specific DNS names: Regional and Zonal.

- A Regional DNS name is of the following format: `VPCendpointID.s3tables.AWSregion.vpce.amazonaws.com`. For example, for the VPC endpoint ID `vpce-1a2b3c4d`, the DNS name generated will be similar to `vpce-1a2b3c4d-5e6f.s3tables.us-east-1.vpce.amazonaws.com`
- A Zonal DNS name is of the following format: `VPCendpointID-AvailabilityZone.s3tables.AWSregion.vpce.amazonaws.com`. For example, For the VPC endpoint ID `vpce-1a2b3c4d-5e6f.`, the DNS name generated will be similar to `vpce-1a2b3c4d-5e6f-us-east-1a.s3tables.us-east-1.vpce.amazonaws.com`

  A Zonal DNS name includes your Availability Zone. You might use Zonal DNS names if your architecture isolates Availability Zones. Endpoint specific S3 DNS names can be resolved from the S3 public DNS domain.

You can also use Private DNS options to simplify routing S3 traffic over VPC endpoints and help you take advantage of the lowest-cost network path available to your application. Private DNS maps the public endpoint of S3 Tables, for instance, `s3tables.region.amazonaws.com`, to a private IP in your VPC. You can use private DNS options to route Regional S3 traffic without updating your S3 clients to use the endpoint-specific DNS names of your interface endpoints.

Accessing table buckets and tables through endpoints using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to access table buckets and tables through the interface endpoints. With the AWS CLI, `aws s3` commands route traffic through the Amazon S3 endpoint. The `aws s3tables` AWS CLI commands use the Amazon S3 Tables endpoint.

An example of an `s3tables` VPC endpoint is `vpce-0123456afghjipljw-nmopsqea.s3tables.region.vpce.amazonaws.com`

An `s3tables` VPC endpoint doesn't include a bucket name. You can access the `s3tables` VPC endpoint using the `aws s3tables` AWS CLI commands.

An example of an s3 VPC endpoint is amzn-s3-demo-bucket.vpce-0123456afghjipljw-nmopsqea.s3.region.vpce.amazonaws.com

You can access the s3 VPC endpoint using the aws s3 AWS CLI commands.

Using the AWS CLI

To access table buckets and tables through interface endpoints using the AWS CLI, use the --region- and --endpoint-url parameters. To perform table bucket and table level actions, use the S3 Tables endpoint URL. To perform object level actions, use the Amazon S3 endpoint URL.

In the following examples, replace the *user input placeholders* with your own information.

Example 1: Use an endpoint URL to list table buckets in your account

```
aws s3tables list-table-buckets --endpoint https://vpce-0123456afghjipljb-aac.s3tables.us-east-1.vpce.amazonaws.com –region us-east-1
```

Example 2: Use an endpoint URL to list tables in your bucket

```
aws s3tables list-tables --table-bucket-arn arn:aws:s3tables:us-east-1:123456789301:bucket/amzn-s3-demo-bucket --endpoint
 https://vpce-0123456afghjipljb-aac.s3tables.us-east-1.vpce.amazonaws.com --region us-east-1
```

Configuring a VPC network when using query engines

Use the following steps to configure a VPC network when using query engines.

1. To get started, you can create or update a VPC. For more information, see Create a VPC.
2. For table and table bucket level operations that route to S3 Tables, create a new interface endpoint. For more information, see Access an AWS service using an interface VPC endpoint.
3. For all object level operations that route to Amazon S3, create a gateway endpoint or a interface endpoint. For more information on gateway endpoints, see Create a gateway endpoint.
4. Next, configure your data resources and launch an Amazon EMR cluster. For more information, see Getting started with Amazon EMR.
5. You can then submit a Spark application with an additional configuration by selecting your DNS names from the VPC endpoint. For example, spark.sql.catalog.ice_catalog.s3tables.endpoint and https://interface-

endpoint.s3tables.*us-east-1*.vpce.amazonaws.com For more information, see Submit work to your Amazon EMR cluster.

Using the dual-stack endpoints to access tables and table buckets

S3 Tables supports dual-stack connectivity for AWS PrivateLink. Dual-stack endpoints allow you to access S3 tables buckets using the Internet Protocol version 6 (IPv6), in addition to the IPv4 protocol, depending on what your network supports. You can access an S3 bucket through a dual-stack endpoint using the following naming convention:

```
s3tables.<region>.api.aws
```

The following are some things you should know before trying to access S3 tables and table buckets over IPv6 in your VPC:

- The client you use to access tables and your S3 client must both have dual-stack enabled.
- IPv6 inbound is not enabled by default for VPC security groups. To allow IPv6 access you will need to add a new rule allowing HTTPS (TCP port 443) to your security group. For more information, see *Configure security group rules* in the *Amazon EC2user guide*
- If your VPC doesn't have IPv6 CIDRs assigned, you will need to manually add an IPv6 CIDR block to your VPC. For more info, see *Add IPv6 support for your VPC* in the *AWS PrivateLink user guide*
- If you use IP address filtering IAM policies they must be updated to handle IPv6 addresses. For more information about managing access permissions with IAM, see Identity and Access Management for Amazon S3.

To create a new VPC endpoint that uses the dual-stack endpoint for S3 Tables use example CLI command:

```
aws ec2 create-vpc-endpoint \
  --vpc-id vpc-id \
  --service-name com.amazonaws.aws-region.s3tables \
  --subnet-ids subnet-1 subnet-2 \
  --vpc-endpoint-type Interface \
  --ip-address-type dualstack \
  --dns-options "DnsRecordIpType=dualstack" \
  --security-group-ids sg-id \
  --region aws-region
```

For more information on creating VPC endpoints see *Create an interface endpoint* in the VPC user guide.

If your network supports IPv6 and you want to update your VPC to enable IPv6 you can use the following CLI command:

```
aws ec2 modify-vpc-endpoint \
  --vpc-endpoint-id vpce-id \
  --ip-address-type dualstack \
  --dns-options "DnsRecordIpType=dualstack" \
  --region aws-region
```

Using VPC endpoint policy conditions with table bucket policies

You can use the `aws:SourceVpce`, `aws:SourceVpc`, and `aws:VpcSourceIp` condition keys in a table bucket policy to restrict access to table bucket resources from a specific VPC or VPC endpoint. For more information about these condition keys, see AWS global condition context keys in the *IAM User Guide*.

When using the Iceberg REST APIs, S3 Tables makes requests to Amazon S3 on your behalf to read and write table metadata. When an Iceberg REST API request is made through a VPC endpoint, the source VPC of the initial request is not preserved in the table metadata requests to Amazon S3. If your table bucket policy restricts access using these condition keys, you must also add a condition for `aws:CalledVia` to allow these table metadata requests from S3 Tables.

The following example table bucket policy denies all S3 Tables actions unless the request comes from the specified VPC endpoint or is a request made by the Amazon S3 Tables Iceberg REST endpoint on your behalf.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictToVPCe",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3tables:*",
            "Resource": [
```

```
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket",
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket/*"
            ],
            "Condition": {
                "StringNotEqualsIfExists": {
                    "aws:SourceVpce": "vpce-1a2b3c4d",
                    "aws:CalledViaLast": "s3tables.amazonaws.com"
                }
            }
        }
    ]
}
```

Restricting access to S3 Tables within the VPC network

Similar to resource-based policies, you can attach an endpoint policy to your VPC endpoint that controls the access to tables and table buckets. In the following example, the interface endpoint policy restricts access to only specific table buckets.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "Policy141511512309",
    "Statement": [
        {
            "Sid": "Access-to-specific-bucket-only",
            "Principal": "*",
            "Action": "s3tables:*",
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket",
                "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket/*"
            ]
        }
    ]
}
```

Security considerations and limitations for S3 Tables

The following list describes which security and access control features and functionality are unsupported or limited for S3 Tables.

- Public access policies are not supported. Users can't modify bucket or table policies to allow public access.
- Presigned URLs to access objects associated with a table are not supported.
- Requests made over HTTP are not supported. Amazon S3 automatically responds with an HTTP redirect for any requests made over HTTP to upgrade the requests to HTTPS.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST APIs.
- Requests made over the Internet Protocol version 6 (IPv6) are supported only for object-level actions over table storage endpoints, and not for the table- and bucket-level actions.
- Table bucket and table access policies are limited to 20 KB in size.

Logging and monitoring for S3 Tables

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 Tables. We recommend collecting monitoring data from your tables in table buckets so that you can more easily debug a multipoint failure if one occurs.

AWS provides several tools for monitoring your S3 Tables resources and responding to potential incidents.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

Amazon S3 Access Logs

Server access logs provide detailed records about the requests that are made to a table bucket. When you enable server access logging on a table bucket, Amazon S3 delivers a log record for

every request to that table bucket to a general purpose bucket that you specify. These logs are useful for security and access auditing. For more information, see Logging requests for S3 Tables using server access logging.

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather, the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring metrics with Amazon CloudWatch.

Logging with AWS CloudTrail for S3 Tables

Amazon S3 is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details. When a supported event activity occurs in Amazon S3, that activity is recorded in a CloudTrail event. You can use AWS CloudTrail trail to log management events and data events for S3 Tables. For more information, see Amazon S3 CloudTrail events and What is AWS CloudTrail? in the *AWS CloudTrailUser Guide*.

CloudTrail management events for S3 Tables

Management events provide information about management operations that are performed on resources in your AWS account.

By default, CloudTrail logs management events for S3 Tables. The `eventsource` for CloudTrail management events for S3 Tables is `s3tables.amazonaws.com`. When you set up your AWS account, CloudTrail management events are enabled by default. The following API actions are tracked by CloudTrail and logged as management events.

- CreateNamespace
- CreateTable
- CreateTableBucket
- DeleteNamespace
- DeleteTable
- DeleteTableBucket
- DeleteTableBucketPolicy
- DeleteTablePolicy
- GetNamespace
- GetTable
- GetTableBucket
- GetTableBucketMaintenanceConfiguration
- GetTableBucketPolicy
- GetTableMaintenanceConfiguration
- GetTableMaintenanceJobStatus
- GetTableMetadataLocation
- GetTablePolicy
- ListNamespaces
- ListTableBuckets
- ListTables
- PutTableBucketMaintenanceConfiguration
- PutTableMaintenanceConfiguration
- PutBucketPolicy
- PutTablePolicy
- RenameTable
- UpdateTableMetadataLocation

For more information on CloudTrail management events, see Logging management events in the *AWS CloudTrail User Guide*.

CloudTrail management events for S3 Tables maintenance

S3 logs automatic maintenance operations as `TablesMaintenanceEvent` management events in CloudTrail. These events occur during operations like compaction and snapshot expiration. For more information about S3 table maintenance, see Maintenance for tables.

How to identify maintenance events

You can identify S3 Tables maintenance events in CloudTrail logs by these attribute values:

- `eventSource: s3tables.amazonaws.com`
- `eventType: AwsServiceEvent`
- `eventName: TablesMaintenanceEvent`
- `userAgent: maintenance.s3tables.amazonaws.com`
- `activityType:`
  - `IcebergCompaction` (for compaction)
  - `IcebergSnapshotManagement` (for snapshot expiration)

For an example of a compaction maintenance event, see Example – CloudTrail log file for a table maintenance management event.

CloudTrail data events for S3 Tables

Data events provide information about the resource operations performed on or in a resource.By default, CloudTrail trails don't log data events, but you can configure trails to log data events.

When you log data events for a trail in CloudTrail, you will choose or specify the resource type. S3 Tables has two resources types, `AWS::S3Tables::Table` and `AWS::S3Tables::TableBucket`.

The following data events are logged to CloudTrail.

- `AbortMultipartUpload`
- `CompleteMultipartUpload`
- `CreateMultipartUpload`
- `GetObject`
- `HeadObject`
- `ListParts`

- `PutObject`
- `UploadPart`

For more information on CloudTrail data events, see Logging data events in the *AWS CloudTrail User Guide*.

For additional information about CloudTrail events for S3 Tables, see the following topics:

          }
```

Logging requests for S3 Tables using server access logging

Server access logging for S3 Tables provides detailed records for the requests that are made to a table bucket. When you enable server access logging on a table bucket, Amazon S3 generates a log record for every request that is made to that table bucket, and delivers the log files to a general purpose bucket that you specify. These logs can help you with security and access auditing, access analysis, and cost attribution.

Server access logging is configured at the table bucket level. By default, Amazon S3 doesn't collect server access logs for table buckets. When you enable logging on a table bucket, Amazon S3 logs requests for all namespaces and tables in that table bucket.

This topic describes server access logging for S3 Tables. If you want to enable server access logging for general purpose buckets instead, see Logging requests with server access logging.

How server access logging works for S3 Tables

You turn server access logging on or off at the table bucket level. To enable or update logging, you use the `PutTableBucketLogging` operation with a `tableBucketLoggingStatus` that contains a `loggingEnabled` element. The `loggingEnabled` element specifies the following values:

- `targetBucket` – Required. The name of the destination general purpose bucket where Amazon S3 delivers the log files.
- `targetPrefix` – Required. The key prefix that Amazon S3 uses for the delivered log objects, for example `logs/`. You can specify an empty prefix. Amazon S3 doesn't add a slash (`/`) after the prefix. For more information, see Log delivery location and key format.
- `targetObjectKeyFormat` – Required. Contains a `partitionedPrefix` element with a `partitionDateSource` value that controls the date that Amazon S3 uses to partition the delivered log objects. The value is either `EventTime` or `DeliveryTime`.

To view the current logging configuration for a table bucket, use the `GetTableBucketLogging` operation. After you enable logging, it might take a few hours before Amazon S3 begins delivering log files to the destination general purpose bucket.

Note

The following limitations apply to server access logging for S3 Tables:

- Server access logging for S3 Tables is available in all AWS Regions.
- Logging is configured at the table bucket level only. When you enable logging, all namespaces and tables in the table bucket are logged. There is no per-namespace or per-table setting.
- Delivery to Amazon CloudWatch Logs is not supported. Amazon S3 delivers S3 Tables server access logs only to a general purpose bucket.
- You can't enable server access logging on AWS managed tables.
- Server access logging for S3 Tables doesn't support the `SimplePrefix` log object key format. For more information, see SimplePrefix.
- Server access logging for S3 Tables doesn't support ACLs.

- Server access logging for S3 Tables doesn't log requests for table buckets that are made to the wrong Regional endpoint. S3 Tables only supports requests that are made to the correct Regional endpoint.

Best-effort log delivery

S3 Tables server access log records are delivered on a best-effort basis. Most requests for a table bucket that is properly configured for logging result in a delivered log record. Most log records are delivered within a few hours of the time that they are recorded, but they can be delivered more frequently.

The completeness and timeliness of server logging is not guaranteed. The log record for a particular request might be delivered long after the request was actually processed, or *it might not be delivered at all*. You might even see a duplicate log record. The purpose of server logs is to give you an idea of the nature of traffic against your table bucket. Although log records are rarely lost or duplicated, be aware that server logging is not meant to be a complete accounting of all requests.

For guaranteed and more complete audit logging, use AWS CloudTrail. CloudTrail captures all API calls for S3 Tables as events. For more information, see Logging with AWS CloudTrail for S3 Tables.

Logging status changes take effect over time

Changes to the logging status of a table bucket take time to actually affect the delivery of log files. For example, if you enable logging for a table bucket, some requests made in the following hour might be logged, and others might not. Suppose that you change the destination bucket for logging from bucket A to bucket B. For the next hour, some logs might continue to be delivered to bucket A, whereas others might be delivered to the new destination bucket B. In all cases, the new settings eventually take effect without any further action on your part.

Destination general purpose bucket requirements

Before you enable server access logging, confirm that the destination general purpose bucket meets the following requirements:

- The destination general purpose bucket must be in the same AWS account and the same AWS Region as the source table bucket. Cross-account and cross-Region delivery are not supported.
- The destination general purpose bucket must use Amazon S3 managed keys (SSE-S3) for default encryption. You can't use server-side encryption with AWS KMS keys (SSE-KMS) or dual-layer

server-side encryption with AWS KMS keys (DSSE-KMS). If the destination general purpose bucket uses SSE-KMS or DSSE-KMS, Amazon S3 might deliver log objects that are encrypted with a key that you can't access.

- The destination general purpose bucket must not have S3 Object Lock enabled.
- The destination general purpose bucket must not have Requester Pays enabled.

For simpler log management, we recommend that you deliver logs to a general purpose bucket that you use only for server access logs.

Permissions for server access logging

Server access logging for S3 Tables requires two kinds of permissions: a bucket policy on the destination general purpose bucket that lets Amazon S3 deliver log files, and AWS Identity and Access Management permissions for the user or role that configures logging.

Destination bucket policy

Amazon S3 delivers log files by using the logging service principal (`logging.s3.amazonaws.com`). You must grant this service principal the `s3:PutObject` permission on the destination general purpose bucket. This uses the service principal model rather than the legacy log delivery access control list (ACL) group.

If you use the Amazon S3 console to enable server access logging, the console automatically updates the bucket policy on the destination general purpose bucket to grant this permission. If you enable logging with the AWS SDKs, the AWS Command Line Interface (AWS CLI), or the Amazon S3 REST API, you must add the bucket policy to the destination general purpose bucket yourself.

The following example bucket policy grants the `s3:PutObject` permission to the logging service principal. To use this bucket policy, replace the *`user input placeholders`* with your own information.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3TablesServerAccessLogsPolicy",
            "Effect": "Allow",
            "Principal": {
```

```
                "Service": "logging.s3.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-logging-bucket/logs/*",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3tables:us-
east-1:111122223333:bucket/amzn-s3-demo-table-bucket"
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                }
            }
        }
    ]
}
```

> **Note**
>
> If there are Deny statements in your bucket policy, make sure that they don't prevent Amazon S3 from delivering access logs.

Permissions to configure logging

To configure server access logging, the user or role that makes the request must have permission to call the `s3tables:PutTableBucketLogging` and `s3tables:GetTableBucketLogging` actions on the table bucket. The following example AWS Identity and Access Management policy grants these permissions. To use this policy, replace the *`user input placeholders`* with your own information.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ConfigureS3TablesServerAccessLogging",
            "Effect": "Allow",
            "Action": [
                "s3tables:PutTableBucketLogging",
                "s3tables:GetTableBucketLogging"
            ],
```

```
            "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-
table-bucket"
        }
    ]
}
```

Enabling or updating server access logging

You can enable or update server access logging for a table bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. In the **Table buckets** list, choose the name of the table bucket that you want to enable server access logging for.
4. Choose **Properties**.
5. In the **Server access logging** section, choose **Edit**.
6. Under **Server access logging**, choose **Enable**.
7. Under **Destination bucket**, specify a general purpose bucket and an optional prefix. If you specify a prefix, we recommend including a forward slash (/) after the prefix to make it easier to find your logs.

> **Note**
>
> Specifying a prefix with a slash (/) makes it simpler for you to locate the log objects. For example, if you specify the prefix value `logs/`, each log object that Amazon S3 creates begins with the `logs/` prefix in its key, as follows:
>
> ```
> logs/2013-11-01-21-32-16-E568B2907131C0C0
> ```
>
> If you specify the prefix value `logs` without a slash, the log object appears as follows:
>
> ```
> logs2013-11-01-21-32-16-E568B2907131C0C0
> ```

8. Under **Source of date used in log object key format**, do one of the following:

   - Choose **S3 event time** so that the year, month, and day in the log object key are based on the time of the S3 event in the delivered file. This option corresponds to the `EventTime` value for `partitionDateSource` in the `partitionedPrefix` element of `targetObjectKeyFormat`, and is the default.
   - Choose **Log file delivery time** so that the year, month, and day in the log object key are based on when the log file was delivered to Amazon S3. This option corresponds to the `DeliveryTime` value for `partitionDateSource` in the `partitionedPrefix` element of `targetObjectKeyFormat`.

9. Choose **Save changes**.

   When you enable server access logging on a table bucket, the console enables logging on the source table bucket. The console also updates the bucket policy for the destination general purpose bucket to grant the `s3:PutObject` permission to the logging service principal (`logging.s3.amazonaws.com`). For more information about this bucket policy, see Destination bucket policy.

   You can view the logs in the destination general purpose bucket. After you enable server access logging, it might take a few hours before the logs are delivered.

Using the AWS CLI

Enable or update logging

To enable or update server access logging, use the `put-table-bucket-logging` command. The following example enables logging on the table bucket `amzn-s3-demo-table-bucket`. It delivers logs to the general purpose bucket `amzn-s3-demo-logging-bucket` under the `logs/` prefix and partitions the log object keys by event time. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3tables put-table-bucket-logging \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket \
    --table-bucket-logging-status '{
        "loggingEnabled": {
            "targetBucket": "amzn-s3-demo-logging-bucket",
            "targetPrefix": "logs/",
            "targetObjectKeyFormat": {
```

```
                "partitionedPrefix": {
                    "partitionDateSource": "EventTime"
                }
            }
        }
    }'
```

To partition log object keys by the time that the log file was delivered, specify `DeliveryTime` for `partitionDateSource`. The `targetObjectKeyFormat` value is required.

View the logging configuration

To view the current logging configuration for a table bucket, use the `get-table-bucket-logging` command.

```
aws s3tables get-table-bucket-logging \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

When logging is enabled, the output looks like the following:

```
{
    "tableBucketLoggingStatus": {
        "loggingEnabled": {
            "targetBucket": "amzn-s3-demo-logging-bucket",
            "targetPrefix": "logs/",
            "targetObjectKeyFormat": {
                "partitionedPrefix": {
                    "partitionDateSource": "EventTime"
                }
            }
        }
    }
}
```

When logging is disabled, the output contains an empty logging status:

```
{
    "tableBucketLoggingStatus": {}
}
```

Disable logging

To disable server access logging, use the `put-table-bucket-logging` command with an empty logging status.

```
aws s3tables put-table-bucket-logging \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket \
    --table-bucket-logging-status '{}'
```

Using the AWS SDKs

The following example uses the AWS SDK for Python (Boto3) to enable server access logging on a table bucket, view the configuration, and then disable logging. Replace the *user input placeholders* with your own information.

```
import boto3

client = boto3.client('s3tables')

table_bucket_arn = 'arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket'

# Enable or update server access logging.
client.put_table_bucket_logging(
    tableBucketARN=table_bucket_arn,
    tableBucketLoggingStatus={
        'loggingEnabled': {
            'targetBucket': 'amzn-s3-demo-logging-bucket',
            'targetPrefix': 'logs/',
            'targetObjectKeyFormat': {
                'partitionedPrefix': {
                    'partitionDateSource': 'EventTime'
                }
            }
        }
    }
)

# View the current logging configuration.
response = client.get_table_bucket_logging(tableBucketARN=table_bucket_arn)
print(response['tableBucketLoggingStatus'])

# Disable server access logging.
client.put_table_bucket_logging(
```

```
    tableBucketARN=table_bucket_arn,
    tableBucketLoggingStatus={}
)
```

Using the REST API

Enable or update logging

To enable or update logging, submit a `PutTableBucketLogging` request. The table bucket ARN is URL-encoded in the request path, and the request body contains the logging status. A successful request returns `204 No Content`.

```
PUT /buckets/arn%3Aaws%3As3tables%3Aus-east-1%3A111122223333%3Abucket%2Famzn-s3-demo-table-bucket/logging HTTP/1.1
Host: s3tables.us-east-1.amazonaws.com
Content-Type: application/json

{
    "tableBucketLoggingStatus": {
        "loggingEnabled": {
            "targetBucket": "amzn-s3-demo-logging-bucket",
            "targetPrefix": "logs/",
            "targetObjectKeyFormat": {
                "partitionedPrefix": {
                    "partitionDateSource": "EventTime"
                }
            }
        }
    }
}
```

View the logging configuration

To retrieve the current logging configuration, submit a `GetTableBucketLogging` request.

```
GET /buckets/arn%3Aaws%3As3tables%3Aus-east-1%3A111122223333%3Abucket%2Famzn-s3-demo-table-bucket/logging HTTP/1.1
Host: s3tables.us-east-1.amazonaws.com
```

Disable logging

To disable logging, submit a `PutTableBucketLogging` request with an empty logging status.

```
PUT /buckets/arn%3Aaws%3As3tables%3Aus-east-1%3A111122223333%3Abucket%2Famzn-s3-demo-table-bucket/logging HTTP/1.1
Host: s3tables.us-east-1.amazonaws.com
Content-Type: application/json

{
    "tableBucketLoggingStatus": {}
}
```

Disabling server access logging

To disable server access logging, send a `PutTableBucketLogging` request with an empty logging status. There is no separate operation to delete the logging configuration. With the AWS CLI, run the `put-table-bucket-logging` command with `--table-bucket-logging-status '{}'`. With Boto3, call `put_table_bucket_logging` with `tableBucketLoggingStatus={}`.

```
aws s3tables put-table-bucket-logging \
    --table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket \
    --table-bucket-logging-status '{}'
```

To disable logging by using the Amazon S3 console, choose the table bucket, choose **Properties**, and in the **Server access logging** section choose **Edit**. Then choose **Disable**, and choose **Save changes**.

When you disable logging, Amazon S3 stops generating log records for the table bucket. Log files that were already delivered to the destination general purpose bucket are not affected.

Log delivery location and key format

Amazon S3 delivers log files to the destination general purpose bucket by using a key that identifies the source table bucket. Log objects use the following key format:

```
s3://targetBucket/targetPrefixaccountId/region/tableBucketName/YYYY/MM/DD/YYYY-MM-DD-hh-mm-ss-UniqueString
```

The following example shows a delivered log object key:

```
s3://amzn-s3-demo-logging-bucket/logs/111122223333/us-east-1/amzn-s3-demo-table-bucket/2026/10/28/2026-10-28-00-00-00-4520D3E0684DC910
```

The key format uses the following parts:

- *targetPrefix* – Amazon S3 appends the prefix exactly as you provide it and doesn't insert a slash (/) after it. A prefix of `logs` without a trailing slash produces a key that begins `logs111122223333/`. To keep log objects organized, end the prefix with a slash (/). If you leave the prefix empty, the key begins with the account ID.
- *accountId* – The AWS account that owns the source table bucket.
- *region* – The AWS Region of the source table bucket.
- *tableBucketName* – The name of the source table bucket. All records for the table bucket, its namespaces, its tables, and data requests are delivered under this single folder. There are no per-table or per-namespace folders.
- *YYYY*/*MM*/*DD*/ – The date folders. S3 Tables server access logs are always date-partitioned.

The `partitionDateSource` value in the `partitionedPrefix` element of `targetObjectKeyFormat` controls how Amazon S3 chooses the date:

- `EventTime` (default) – The date folders are based on the date of the request. The time in the file name is always `00-00-00`.
- `DeliveryTime` – The date folders are based on the date that the log file was delivered. The time in the file name is the actual delivery time.

Server access log format for S3 Tables

Server access logs for S3 Tables are delivered in space-delimited text format. Each log record represents one request and contains 25 fields in the following order:

```
table_bucket_arn [request_time] table_arn namespace_name table_name key object_size
 remote_ip requester request_id operation http_status error_code bytes_sent
 total_time turnaround_time "referer" "user_agent" signature_version cipher_suite
 authentication_type host_header tls_version request_time_iso source_region
```

In a log record, the `request_time` field is enclosed in square brackets, and the `referer` and `user_agent` fields are enclosed in double quotation marks. A hyphen (-) indicates a field that doesn't apply to the request.

The following table describes each field.

Field	Description	Example
table_bucket_arn	The ARN of the table bucket that received the request.	arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket
request_time	The time that the request was received, enclosed in square brackets.	[28/Oct/2026:13:46:39 +0000]
table_arn	The ARN of the table, or - for table bucket and namespace requests.	arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket/table/cdae79fb-03e3-49dc-92c7-10e279e37e8f
namespace_name	The namespace in the request, or -.	sal_ns
table_name	The table name in the request, or -.	events
key	The object key for data requests, or -.	metadata/00000-a3001105-metadata.json
object_size	The object size in bytes for data requests, or -.	756
remote_ip	The IP address of the requester.	15.248.6.220
requester	The IAM identity of the requester.	arn:aws:sts::111122223333:assumed-role/Admin/example-session
request_id	The request ID.	6TBZ2YZN2PGW74S8
operation	The operation that was performed.	S3Tables.GetTable

Field	Description	Example
`http_status`	The HTTP status code of the response.	`200`
`error_code`	The error code, or `-` if there was no error.	`NotFoundException`
`bytes_sent`	The number of response bytes sent, or `-`.	`735`
`total_time`	The total time to serve the request, in milliseconds.	`49`
`turnaround_time`	The time that Amazon S3 spent processing the request, in milliseconds.	`49`
`referer`	The value of the HTTP Referer header, enclosed in double quotation marks.	`"https://analytics.example.com/"`
`user_agent`	The value of the HTTP User-Agent header, enclosed in double quotation marks.	`"aws-cli/2.34.34"`
`signature_version`	The signature version that was used to authenticate the request.	`SigV4`
`cipher_suite`	The TLS cipher suite that was used for the request.	`TLS_AES_128_GCM_SHA256`
`authentication_type`	The authentication type: `AuthHeader` for an authorization header, or `QueryString` for a presigned URL.	`AuthHeader`
`host_header`	The endpoint that was used for the request.	`s3tables.us-east-2.amazonaws.com`

Field	Description	Example
`tls_version`	The TLS version that was used for the request.	`TLSv1.3`
`request_time_iso`	The time that the request was received, in ISO 8601 format with milliseconds.	`2026-10-28T13:46:39.000Z`
`source_region`	The AWS Region that the request came from, or `-`.	`us-west-2`

Note

The `operation` field is declared as `S3Tables.`*`ActionName`* for S3 Tables API requests and Iceberg REST catalog endpoint requests, or `REST.`*`HTTP_method`*`.`*`resource_type`* for requests to table storage. For Iceberg REST catalog endpoint requests, *`ActionName`* is the IAM action that the request is authorized as. For example, a `loadTable` request is logged as `S3Tables.GetTableMetadataLocation`.

The following example shows a log record for a `GetTable` request.

```
arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-demo-table-bucket [28/
Oct/2026:13:46:35 +0000] arn:aws:s3tables:us-east-2:111122223333:bucket/amzn-s3-
demo-table-bucket/table/cdae79fb-03e3-49dc-92c7-10e279e37e8f sal_ns events - -
 15.248.6.88 arn:aws:sts::111122223333:assumed-role/Admin/example-session c4e215be-
ad2b-4b55-a190-4225aada1885 S3Tables.GetTable 200 - 735 49 49 "-" "aws-cli/2.34.34"
 SigV4 TLS_AES_128_GCM_SHA256 AuthHeader s3tables.us-east-2.amazonaws.com TLSv1.3
 2026-10-28T13:46:35.634Z us-west-2
```

Managing log retention

A destination general purpose bucket that receives server access logs can accumulate many log objects over time. You can use Amazon S3 Lifecycle configuration to set rules so that Amazon S3 automatically deletes log objects after a specified period. If you specified a prefix in your logging configuration, you can scope the lifecycle rule to that prefix. For example, if your log objects

have the prefix `logs/`, you can create a lifecycle rule to delete all objects with that prefix after a specified number of days. For more information, see Managing the lifecycle of objects.

Keep the following behavior in mind when you manage log retention:

- If you delete a table or a table bucket, the log files that were already delivered to the destination general purpose bucket persist. They are managed independently of the source table bucket.
- If you delete the destination general purpose bucket, the logging configuration remains on the table bucket, but Amazon S3 silently drops log records until you recreate the destination general purpose bucket or update the logging configuration.

Charges for server access logging

There is no additional S3 Tables charge for generating and delivering server access logs. You pay the standard Amazon S3 charges for the destination general purpose bucket, including storage of the delivered log files, requests, and data transfer for accessing the log files. You can delete the log files at any time. For current rates, see Amazon S3 pricing.

Querying server access logs by using Amazon Athena

You can analyze S3 Tables server access logs by using Amazon Athena. The following example shows how to create a database and table in Athena, and then query the delivered log files. Replace the *`user input placeholders`* with your own information. For more information about using Athena with S3 Tables, see Querying Amazon S3 tables with Athena.

1. Open the Athena console at https://console.aws.amazon.com/athena/.
2. In the query editor, run the following command to create a database. Replace *`s3_tables_access_logs_db`* with the name that you want to give to your database.

```
CREATE DATABASE s3_tables_access_logs_db
```

3. Run the following command to create a table schema in the database. For `LOCATION`, enter the destination general purpose bucket, prefix, account ID, Region, and source table bucket name. Amazon S3 appends the prefix without inserting a slash, so there is no slash between *`targetPrefix`* and the account ID.

```
CREATE EXTERNAL TABLE s3_tables_access_logs_db.s3_tables_logs(
  `table_bucket_arn` STRING,
  `request_time` STRING,
```

```
  `table_arn` STRING,
  `namespace_name` STRING,
  `table_name` STRING,
  `key` STRING,
  `object_size` BIGINT,
  `remote_ip` STRING,
  `requester` STRING,
  `request_id` STRING,
  `operation` STRING,
  `http_status` STRING,
  `error_code` STRING,
  `bytes_sent` BIGINT,
  `total_time` STRING,
  `turnaround_time` STRING,
  `referer` STRING,
  `user_agent` STRING,
  `signature_version` STRING,
  `cipher_suite` STRING,
  `authentication_type` STRING,
  `host_header` STRING,
  `tls_version` STRING,
  `request_time_iso` STRING,
  `source_region` STRING)
PARTITIONED BY (
  `timestamp` string)
ROW FORMAT SERDE
  'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
  'input.regex'='([^ ]*) \\[(.*?)\\] ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) (\"[^\"]*
\"|-) (\"[^\"]*\"|-) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*).*$')
STORED AS INPUTFORMAT
  'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
  'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
  's3://amzn-s3-demo-logging-bucket/logs/111122223333/us-east-1/amzn-s3-demo-table-
bucket/'
TBLPROPERTIES (
  'projection.enabled'='true',
  'projection.timestamp.format'='yyyy/MM/dd',
  'projection.timestamp.interval'='1',
  'projection.timestamp.interval.unit'='DAYS',
  'projection.timestamp.range'='2026/01/01,NOW',
```

```
  'projection.timestamp.type'='date',
  'storage.location.template'='s3://amzn-s3-demo-logging-
bucket/logs/111122223333/us-east-1/amzn-s3-demo-table-bucket/${timestamp}')
```

4. In the navigation pane, under **Database**, choose your database.
5. Under **Tables**, choose **Preview table** next to your table name. In the **Results** pane, you see data from the server access logs. You can now query the S3 Tables server access logs.

Monitoring metrics with Amazon CloudWatch

You can use Amazon CloudWatch metrics to track performance, detect anomalies, and monitor the operational health of tables. There are several sets of CloudWatch metrics that you can use with S3 Tables.

Daily storage metrics for tables and table buckets

Monitor the amount of data stored in tables and table buckets, including total size in bytes and number of files. These metrics track total storage bytes per access tier and file counts at the table bucket, table, and namespace level. Storage metrics for S3 Tables are reported once per day and are provided to all customers at no additional cost.

Table maintenance metrics

Monitor automated maintenance operations performed by Amazon S3 on your tables, such as compaction. These metrics track the number of bytes and files processed during maintenance activities. Maintenance metrics for S3 Tables are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor S3 Tables requests to quickly identify and act on operational issues. These CloudWatch metrics can be optionally enabled for individual table buckets. Request metrics for S3 Tables are reported once every minute and are billed at the same rate as CloudWatch custom metrics. Request metrics include:

- counts of data plane operations (GET, PUT, HEAD, POST)
- bytes transferred
- latency measurements
- error rates

Note

Best-effort CloudWatch metrics delivery
CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.
The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time.
It is not meant to be a complete accounting of all requests. It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

Metrics and dimensions

The storage metrics and dimensions that S3 Tables sends to Amazon CloudWatch are listed in the following tables.

Note

Best-effort CloudWatch metrics delivery
CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.
The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time.
It is not meant to be a complete accounting of all requests. It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

Daily storage metrics for table buckets in CloudWatch

The `AWS/S3/Tables` namespace includes the following daily storage metrics which are available at no additional cost. You can filter these metrics by table bucket, table, or namespace name.

Daily storage metrics

Metric Name	Description	Units	Statistics	Granularity
Total Bucket Storage	The amount of storage in bytes used by all tables in a table bucket	Bytes	Sum	Daily
Total number of files	The total count of all files stored in a table bucket	Count	Sum	Daily

Table maintenance metrics

The `AWS/S3/Tables` namespace includes the following table maintenance metrics which are available at no additional cost. You can filter these metrics by table bucket, table, or namespace name.

Table maintenance metrics

Metric Name	Description	Units	Statistics	Granularity
CompactionBytesProcessed	The number of bytes processed during table compaction operations	Bytes	Sum	Daily
CompactionObjectsCount	The number of objects processed during table compaction operations	Count	Sum	Daily

Request metrics for tables and table buckets in CloudWatch

The `AWS/S3/Tables` namespace includes the following request metrics which are billed at the same rate as CloudWatch custom metrics. You can filter these metrics by table bucket, table, or namespace name.

> **Note**
>
> Request metrics are published only when all three dimensions (`TableBucketName`, `Namespace`, `TableName`) can be resolved. Requests that target a table or namespace that does not exist do not appear in CloudWatch request metrics. To monitor these requests, use AWS CloudTrail.

Request metrics

Metric Name	Description	Units	Statistics	Granularity
All requests count	The total number of HTTP requests made to a table bucket, regardless of type. This metric does not include `GetTableMetadataLocation` or `UpdateTableMetadataLocation` requests.	Count	Sum	1-minute
Get requests count	The number of HTTP GET requests made to retrieve objects from tables. This metric does not include `GetTableMetadataLocation` requests.	Count	Sum	1-minute
Put requests count	The number of HTTP PUT requests made to add objects to tables. This metric does not include `UpdateTableMetadataLocation` requests.	Count	Sum	1-minute
Head requests count	The number of HTTP HEAD requests made to retrieve metadata from tables.	Count	Sum	1-minute

Metric Name	Description	Units	Statistics	Granularity
Post requests count	The number of HTTP POST requests made to tables.	Count	Sum	1-minute
UpdateTableMetadataLocation requests count	The number of `UpdateTableMetadataLocation` requests made to a table bucket. This metric is not included in `Put requests count` or `All requests count`.	Count	Sum	1-minute
GetTableMetadataLocation requests count	The number of `GetTableMetadataLocation` requests made to a table bucket. This metric is not included in `Get requests count` or `All requests count`.	Count	Sum	1-minute
BytesDownloaded	The number of bytes downloaded for table requests.	Bytes	Sum	1-minute
BytesUploaded	The number of bytes uploaded for table requests.	Bytes	Sum	1-minute
4xxErrors	The count of HTTP 4xx client error status codes returned.	Count	Sum	1-minute
5xxErrors	The count of HTTP 5xx server error status codes returned.	Count	Sum	1-minute

Metric Name	Description	Units	Statistics	Granularity
FirstByte Latency	The per-request time from the complete request being received to when the response starts being returned.	Milliseconds	Sum	1-minute
TotalRequestLatency	The elapsed per-request time from the first byte received to the last byte sent.	Milliseconds	Sum	1-minute

S3 Tables dimensions in CloudWatch

The following dimensions are used to filter S3 Tables metrics.

S3 Tables dimensions

Dimension Name	Description	Example Value
`TableBucketName`	The name of the Amazon S3 table bucket	`my-table-bucket`
`Namespace`	The namespace within the table bucket that contains one or more tables	`my-department`
`TableName`	The name of a specific table within a namespace	`transactions`

Accessing CloudWatch metrics

You can monitor S3 Tables metrics using the CloudWatch Console, the AWS CLI, or the CloudWatch API. This section explains how to access your metrics using these different methods.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.

3. In the buckets list, choose the name of the bucket that contains the tables you want to see metrics for.
4. Choose the **Metrics** tab.
5. Choose the **View in CloudWatch** in any metrics pane to navigate to the CloudWatch console and see your available metrics in the `AWS/S3/Tables` namespace.

Using the AWS CLI

To list metrics for S3 Tables using the AWS CLI, use the `list-metrics` command with the `--namespace` parameter set to `AWS/S3/Tables`:

```
aws cloudwatch list-metrics --namespace AWS/S3/Tables
```

To get statistics for a specific S3 Tables metric, use the `get-metric-statistics` command. For example:

```
aws cloudwatch get-metric-statistics \
--namespace AWS/S3/Tables \
--metric-name TotalBucketStorage \
--dimensions Name=TableBucketName,Value=MyTableBucket \
--start-time 2025-03-01T00:00:00 \
--end-time 2025-03-02T00:00:00 \
--period 86400 \
--statistics Average
```

Best Practices

- When retrieving metrics, set the Period value based on the metric's granularity. For daily metrics (like storage metrics), use 86400 seconds (24 hours). For minute-level metrics (like request metrics), use 60 seconds.
- Use dimensions appropriately to filter metrics to the desired scope (table bucket, namespace, or individual table level).
- Consider using metric math to create derived metrics that better match your monitoring needs.

- Amazon CloudWatch Concepts

- Using Amazon CloudWatch Dashboards

Managing CloudWatch metrics

Storage metrics are enabled by default for all Amazon S3 tables and table buckets. You can enable or disable additional Request metrics through the console, AWS Command Line Interface (AWS CLI), or AWS SDKs.

Prerequisites

- Requires `s3table:PutTableBucketMetricsConfiguration` IAM permission

> **Note**
>
> S3 Tables Request metrics are billed at the same rate as CloudWatch custom metrics.

Using the AWS Management Console

To enable or disable additional metrics

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Table buckets**.
3. In the buckets list, choose the name of the table bucket that contains the tables you want to request metrics for.
4. Choose the **Metrics** tab.
5. From the Request metrics panel, choose **Edit**.
6. Select **Enabled** or **Disabled**, then **Save changes**.

Using the AWS CLI

These examples show how to enable or disable request metrics for table buckets by using the AWS CLI. To use these commands, replace the *`user input placeholders`* with your own information.

Example: To enable request metrics for a table bucket:

```
aws s3tables put-table-bucket-metrics-configuration \
```

```
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Example: To disable request metrics for a table bucket:

```
aws s3tables delete-table-bucket-metrics-configuration \
--table-bucket-arn arn:aws:s3tables:us-east-1:111122223333:bucket/amzn-s3-demo-table-bucket
```

Working with S3 Vectors and vector buckets

What is Amazon S3 Vectors?

Amazon S3 Vectors delivers purpose-built, cost-optimized vector storage for AI agents, inference, RAG, and semantic search. S3 Vectors is designed to provide the same elasticity, durability, and availability as Amazon S3 and delivers subsecond latency for infrequent queries and as low as 100 milliseconds for more frequent queries. You get a dedicated set of API operations to store, access, and query vector data without provisioning any infrastructure. S3 Vectors consists of several key components that work together:

- **Vector buckets** – A new bucket type that's purpose-built to store and query vectors.
- **Vector indexes** – Within a vector bucket, you can organize your vector data within vector indexes. You perform similarity queries on your vector data within vector indexes.
- **Vectors** – You store vectors in your vector index. For similarity search and AI applications, vectors are created as vector embeddings which are numerical representations that preserve semantic relationships between content (such as text, images, or audio) so similar items are positioned closer together. S3 Vectors can perform similarity searches based on semantic meaning rather than exact matching through comparing how close vectors are to each other mathematically. When adding vector data to a vector index, you can also attach metadata for future filtering queries based on a set of conditions (for example, timestamps, categories, and user preferences).

Writes to S3 Vectors are strongly consistent, which means that you can immediately access the most recently added data. As you write, update, and delete vectors over time, S3 Vectors automatically optimizes the vector data to achieve the best possible price performance for vector storage, even as the data sets scale and evolve. You can control access to your vector data with the existing access control mechanisms of Amazon S3, including bucket and IAM policies. For more information about vector index limits per bucket and vector limits per index, see Limitations and restrictions.

Use cases: Similarity searches across large datasets

Similarity searches allow you to find items that are conceptually related to each other based on their vector representations, rather than exact keyword matches. These searches identify content with similar meanings or characteristics, even when the exact words or visual elements differ.

Common use cases for similarity search with S3 Vectors include:

- **Medical imaging** - Find similarities in millions of medical images to assist with diagnosis and treatment planning
- **Copyright infringement** - Identify potentially derivative content across large media libraries
- **Image deduplication** - Detect and remove duplicate or near-duplicate images from large image collections
- **Video understanding** - Search for specific scenes or content within video assets
- **Enterprise document search** - Enable semantic search across corporate documents to find relevant information based on meaning
- **Personalization** - Deliver tailored recommendations by finding similar items

You should use S3 Vectors if you want to build cost-effective vector search and agentic AI applications with sub-second search times. With vector buckets, you only pay for what you use, and could save costs for uploading, storing, and querying vector embeddings. For more information about pricing, see Amazon S3 pricing.

Features of S3 Vectors

Purpose-built storage for vectors

S3 Vectors is the first purpose-built object storage in the cloud to store and query vectors. Vector buckets are designed to provide cost-effective, elastic, and durable storage for vector data.

Vector embeddings are transforming how customers use and retrieve their unstructured data, from detecting similarities across medical images, finding anomalies in thousands of hours of video footage, navigating through large code bases, and identifying the most relevant case law for a given legal matter. These emerging applications combine with embedding models to encode the semantic meaning of data (for example, text, images, video, code) as numerical vector embeddings.

Within a vector bucket, you organize your vector data within vector indexes, without provisioning infrastructure. As you write, update, and delete vectors over time, S3 Vectors automatically optimize the vector data to achieve the best possible price performance for vector storage, even as the data sets scale and evolve. For more information about vector index limits per bucket and vector limits per index, see Limitations and restrictions.

Perform similarity queries

With S3 Vectors, you can perform queries to find the most similar vectors to a query vector, with sub-second response times for infrequent queries and as low as 100 milliseconds for more frequent queries. S3 Vectors is ideal for workloads where queries are less frequent.

Metadata filtering

You can attach metadata (for example, year, author, genre, and location) as key-value pairs to your vectors. By default, all metadata is filterable unless you explicitly specify it as non-filterable. You can use filterable metadata to filter your query results based on specific attributes, enhancing the relevance of your queries. Vector indexes support string, number, boolean, and list types of metadata. For more information about metadata size limits per vector and filterable metadata size limits per vector, see Limitations and restrictions.

Access management and security

You can manage access for resources in vector buckets with IAM and Service Control Policies in AWS Organizations. S3 Vectors uses a different service namespace than Amazon S3: the `s3vectors` namespace. Therefore, you can design policies specifically for the S3 Vectors service and its resources. You can design policies to grant access to individual vector indexes, all vector indexes within a vector bucket, or all vector buckets in an account. All Amazon S3 Block Public Access settings are always enabled for vector buckets and cannot be disabled.

Integration with AWS services

S3 Vectors integrates with other AWS services to enhance your vector processing capabilities:

- **Amazon OpenSearch Service** - Optimize vector storage costs while continuing to use OpenSearch API operations. This is ideal for workloads that need advanced search functionality such as hybrid search, aggregations, advanced filtering, and faceted search. You can also export a snapshot of an S3 vector index to Amazon OpenSearch Serverless for high QPS and low latency vector search.
- **Amazon Bedrock Knowledge Bases** - Select a vector index in S3 Vectors as your vector store to save on storage costs for retrieval augmented generation (RAG) applications.
- **Amazon Bedrock in SageMaker Unified Studio** - Develop and test knowledge bases using S3 Vectors as your vector store.

Tutorial: Getting started with S3 Vectors

In this tutorial, you create an S3 vector bucket and a vector index in an AWS Region in the Amazon S3 console. Next, you use an Amazon Bedrock embedding model to generate vector embeddings of your data and store them in your vector index to perform semantic searches.

To get started, sign up for an AWS account if you don't already have one. For more information about setting up with an account, see Getting started with Amazon S3.

Topics

- Step 1: Create a vector bucket with the console
- Step 2: Create a vector index in a vector bucket with the console
- Step 3: Insert vectors into a vector index with the SDK for Python (Boto3)
- Step 4. Query vectors in a vector index with the SDK for Python (Boto3)
- (Optional) Automate vector embedding creation with the S3 Vectors Embed CLI
- (Optional) Integrate S3 Vectors with Amazon Bedrock Knowledge Bases
- (Optional) Integrate S3 Vectors with Amazon OpenSearch

Step 1: Create a vector bucket with the console

S3 vector buckets are a type of Amazon S3 bucket that's purpose-built to store and query vectors. You use dedicated API operations to write and query vector data. You can control access to your vector data with access control mechanisms such as IAM identity-based policies and resource-based policies.

In this step, you use the Amazon S3 console to create your first vector bucket. For other ways to create a vector bucket, see Creating a vector bucket.

To create a vector bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Vector buckets**.
3. On the **Vector buckets** page, choose **Create vector bucket**.
4. On the **Create vector bucket** page, for the **Vector bucket name** field, enter a name. In this tutorial, we use `media-embeddings` as the vector bucket name. Vector bucket names must be

3 to 63 characters and unique within an AWS Region. Valid characters are lowercase letters (a-z), numbers (0-9), and hyphens (-).

> **Note**
>
> The vector bucket name can't be changed after the bucket is created.

5. Under **Encryption**, choose **Specify encryption type**. You have the option to specify encryption type as **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or the default **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. In this tutorial, we choose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. For more information about setting encryption configuration for vector buckets, see Data protection and encryption in S3 Vectors.

> **Note**
>
> The encryption type can't be changed after the vector bucket is created.

6. Under **Tags (Optional)**, you can add tags as key-value pairs to help organize and specify permissions for your vector buckets. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector bucket. For more information, see Using tags with S3 vector buckets.
7. Choose **Create vector bucket**.

Step 2: Create a vector index in a vector bucket with the console

> **Note**
>
> Choose your vector index configuration parameters carefully. After you create a vector index, you can't update the vector index name, dimension, distance metric, or non-filterable metadata keys. To change any of these values, you must create a new vector index.

In this step, you create a vector index in your vector bucket. The vector index is used to store and query your vector embeddings. For more information about vector indexes, see Vector indexes.

To create a vector index

1. Navigate to the newly created vector bucket in the **Vector buckets** list on the Amazon S3 console.
2. Choose **Create vector index**.
3. On the **Create vector index** page, enter a name in the **Vector index name** field. In this tutorial, we use *`movies`* as the vector index name.

   Vector index names must be 3 to 63 characters and unique within this vector bucket. Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.).

   The vector index name can't be changed after index creation.
4. Under **Dimension**, specify a numeric value between 1 and 4096 that determines how many numbers will be in each vector that's generated by your vector embedding model. Embedding models are specialized machine learning (ML) models that convert data (such as text or images) into numerical vectors. Embedding models typically produce outputs between 500-2000 dimensions, with each dimension being a floating-point number. In this tutorial, we'll use the Titan Text v2 embedding model from Amazon Bedrock. This embedding model uses 1024-dimensional vectors as the default, so we'll set dimension for the vector index to `1024`.

   The dimension value can't be changed after index creation. Carefully specify the dimension value based on your embedding model's recommendations.
5. Under **Distance metric**, choose either **Cosine** (which measures angular similarity) or **Euclidean** (which measures straight-line distance) as the distance metric to define how similarity between vectors is calculated during queries. In this tutorial, we choose **Cosine**.

   The distance metric can't be changed after index creation. Carefully choose the distance metric based on your embedding model's recommendations.
6. Under **Additional settings (optional)**, you can specify non-filterable metadata keys to store supplementary information alongside your vector embeddings.

   > **Note**
   >
   > You can attach filterable metadata as key-value pairs to each vector when you insert vector data after index creation. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata

keys that are specified as non-filterable during vector index creation are excluded from filtering.

Each non-filterable metadata key must be between 1 to 63 characters and unique within the vector index. These keys are useful for storing reference information that you don't need to filter on during similarity queries. For example, when working with text embeddings, you might want to preserve the original text chunks for reference purposes. In this tutorial, we add a non-filterable metadata key that's named `source_text` to store the text data that we want to create vector embeddings for.

You can't update non-filterable metadata keys after index creation. Plan your metadata structure carefully.

7. Under **Encryption**, choose **Specify encryption type**. You have the option to use the bucket level encryption settings or override the encryption settings for the vector index. If you override the bucket-level settings, you have the option to specify encryption type for the vector index as **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or the **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. In this tutorial, we choose to **Use bucket settings for encryption**. For more information about setting encryption configuration for vector buckets and indexes, see Data protection and encryption in S3 Vectors.
8. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see Using tags with S3 vector buckets.
9. Choose **Create vector index**.

Verify that your new vector index appears inside the bucket.

Step 3: Insert vectors into a vector index with the SDK for Python (Boto3)

To insert, list, and query vectors, use the AWS SDKs, AWS CLI, or Amazon S3 REST API.

This step is to insert vector embeddings to your vector index with the PutVectors API operation.

You must first generate vector embeddings by using the embedding model of your choice. If you use Amazon Bedrock, generate embeddings by using the InvokeModel API operation to specify your preferred embedding model. Alternatively, to generate and insert vector embeddings with a single command, see (Optional) Automate vector embedding creation with the S3 Vectors Embed CLI.

The following example code generates 1024-dimensional vector embeddings with the Titan Text Embeddings V2 model from Amazon Bedrock by using the AWS SDK for Python (Boto3), and stores them in your vector index by using the `PutVectors` API. Along with each vector, we attach key-value pairs as filterable metadata. Additionally, we use a non-filterable metadata key that's named *`source_text`* to preserve the original text from which each vector is derived. To maximize request throughput and optimize for speed and efficiency, we recommend that you insert and delete vectors in batches. For more information, see S3 Vectors best practices.

```
# Populate a vector index with embeddings from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Texts to convert to embeddings.
texts = [
    "Star Wars: A farm boy joins rebels to fight an evil empire in space",
    "Jurassic Park: Scientists create dinosaurs in a theme park that goes wrong",
    "Finding Nemo: A father fish searches the ocean to find his lost son"
]

# Generate vector embeddings.
embeddings = []
for text in texts:
    response = bedrock.invoke_model(
        modelId="amazon.titan-embed-text-v2:0",
        body=json.dumps({"inputText": text})
    )

    # Extract embedding from response.
    response_body = json.loads(response["body"].read())
    embeddings.append(response_body["embedding"])

# Write embeddings into vector index with metadata.
```

```
s3vectors.put_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    vectors=[
        {
            "key": "Star Wars",
            "data": {"float32": embeddings[0]},
            "metadata": {"source_text": texts[0], "genre":"scifi"}
        },
        {
            "key": "Jurassic Park",
            "data": {"float32": embeddings[1]},
            "metadata": {"source_text": texts[1], "genre":"scifi"}
        },
        {
            "key": "Finding Nemo",
            "data": {"float32": embeddings[2]},
            "metadata": {"source_text": texts[2], "genre":"family"}
        }
    ]
)
```

Step 4. Query vectors in a vector index with the SDK for Python (Boto3)

After you store your vectors embeddings in the vector index, you can perform a similarity search by using the QueryVectors API operation.

You must first generate your query vector embeddings by using the same embedding model that's used during insertion in Step 3: Insert vectors into a vector index with the SDK for Python (Boto3). In this tutorial, use the Titan Text Embeddings V2 model from Amazon Bedrock through the SDK for Python (Boto3).

You can perform a similarity search to return the closest matching vectors. In a similarity search, you can optionally filter by using metadata keys to narrow results based on specific criteria while maintaining semantic relevance.

```
# Query a vector index with an embedding from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
```

```
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Query text to convert to an embedding.
input_text = "adventures in space"

# Generate the vector embedding.
response = bedrock.invoke_model(
    modelId="amazon.titan-embed-text-v2:0",
    body=json.dumps({"inputText": input_text})
)

# Extract embedding from response.
model_response = json.loads(response["body"].read())
embedding = model_response["embedding"]

# Query vector index.
response = s3vectors.query_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))

# Query vector index with a metadata filter.
response = s3vectors.query_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    filter={"genre": "scifi"},
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))
```

(Optional) Automate vector embedding creation with the S3 Vectors Embed CLI

Amazon S3 Vectors Embed CLI is a standalone command line tool that simplifies the process of working with vector embeddings in S3 Vectors. With single commands, you can create vector embeddings for your data by using Amazon Bedrock, and store and query them in your S3 vector index. The tool supports the following commands:

- `s3vectors-embed put`: Generate vector embeddings of text, file content, or S3 objects, and store them as vectors in an S3 vector index.
- `s3vectors-embed query`: Embed a query input and search for similar vectors in an S3 vector index.

For more information about the commands and usage, see the Amazon S3 Vectors Embed CLI GitHub repository.

(Optional) Integrate S3 Vectors with Amazon Bedrock Knowledge Bases

Amazon Bedrock Knowledge Bases integrates with S3 Vectors for cost effective and long-term storage of vector datasets.

Prerequisites

Follow the prerequisites to ensure you have necessary permissions for creating an Amazon Bedrock knowledge base.

- Appropriate IAM permissions for both S3 Vectors and Amazon Bedrock services. For more information about IAM permissions for S3 Vectors, see Identity and Access management in S3 Vectors.
- Your source documents prepared for ingestion into the knowledge base.
- An understanding of your embedding model requirements.

Create an Amazon Bedrock knowledge base with S3 Vectors in the console

Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow. When you create a knowledge base with S3 Vectors, Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your

vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data.

To create an Amazon Bedrock knowledge base with S3 Vectors in the console

1. Sign in to the AWS Management Console using an IAM role with Amazon Bedrock permissions, and open the Amazon Bedrock console at https://console.aws.amazon.com/bedrock/.
2. In the left navigation pane, choose **Knowledge Bases**.
3. In the **Knowledge Bases** section, choose **Create**. In the dropdown list, choose **Knowledge Base with vector store**.
4. Keep the **Knowledge Base name**, **Knowledge Base description**, and **IAM permissions** at their default values in this tutorial.
5. For **Choose a data source type**, choose the data source to connect your knowledge base to. In this tutorial, choose **Amazon S3**.
6. (Optionally) Provide any **Tags** or **Application logs**.
7. Choose **Next**.
8. On the **Configure data source** page, keep the **Data source name**, **Data source location**, **Parsing strategy**, and **Chunking strategy** at the default settings in this tutorial.
9. In the **S3 URI**, enter the S3 general purpose bucket that contains your source files, or choose **Browse S3** and choose the S3 general purpose bucket.
10. For encrypted S3 data, select **Add customer-managed KMS key for S3 data** and specify your customer-managed KMS key.
11. Choose **Next** to proceed to the next step that specifies the **Embeddings model** and **Vector store** options.
12. In the **Embeddings model** section, choose **Select model** and choose an embedding model compatible for use with S3 Vectors. You must use floating-point embeddings. Binary type isn't supported.
13. (Optional) Expand the **Additional configurations** section to see the following configuration options (not all models support all configurations):

    - **Embeddings type** – Whether to convert the data to floating-point (float32) vector embeddings (more precise, but more costly) or binary vector embeddings (less precise, but less costly). To integrate with S3 Vectors, you must choose **Floating-point vector embeddings**.
    - **Vector dimensions** – Choose the embedding models recommended dimension size.

14. In the **Vector store** section, choose the recommended method **Quick create a new vector store** for automatic setup of a new vector bucket, or choose **Use an existing vector store** to use an existing vector bucket if available. For information about using an existing vector store flow, see Prerequisites for using a vector store you created for a knowledge base in the *Amazon Bedrock User Guide*.
15. For **Additional configurations** – By default, your vector bucket uses server-side encryption with Amazon S3 managed keys (SSE-S3). You can choose to use your own KMS key for server-side encryption with AWS Key Management Service keys (SSE-KMS) for enhanced control over encryption settings.
16. Choose **Next** to review the Knowledge Base details and then choose **Create Knowledge Base**.

> **Note**
>
> The time that it takes to create a knowledge base depends on your specific configurations. When the creation of a knowledge base completes, the status of the knowledge base changes to state it is either ready or available. Once your knowledge base is ready and available, sync your data source for the first time or whenever you want to keep your content up to date. To sync your data source, choose your knowledge base in the console and choose **Sync** within the data source overview section.

(Optional) Integrate S3 Vectors with Amazon OpenSearch

Amazon OpenSearch Service is a fully managed service that simplifies the deployment, scaling, and operation of OpenSearch in the AWS Cloud. There are two integrations between S3 Vectors and OpenSearch. One is to export vector data from S3 Vectors to OpenSearch Serverless for high-performance search capabilities. The other uses S3 Vectors as a cost-effective storage engine within OpenSearch while maintaining access to OpenSearch functionality.

For more information, see Using S3 Vectors with OpenSearch Service.

Vector buckets

Vector buckets are a type of Amazon S3 bucket designed specifically for storing and querying vector data. Vector buckets use dedicated APIs to manage vector data efficiently and reduce costs of upload, storing, and querying vector embeddings. Vector buckets provide the foundation for

organizing your vector data into indexes, enabling you to perform similarity searches across large datasets while benefiting from the availability, durability, scalability, and cost-effectiveness of Amazon S3.

Vector buckets are optimized for long-term vector storage with sub-second search times. You can perform similarity queries on your vector data and optionally attach metadata to filter queries based on specific conditions such as dates, categories, or user preferences.

Each vector bucket has a unique Amazon Resource Name (ARN) and resource policy attached to it. The ARNs of vector buckets follow the following format:

```
arn:aws:s3vectors:Region:OwnerAccountID:bucket/bucket-name
```

Within a vector bucket, you create vector indexes to store and query your data. Each vector bucket exists within a specific AWS Region and you can create multiple vector indexes inside a vector bucket. Vector buckets support security and access control mechanisms, including IAM identity-based policies and bucket policies. You can use bucket policies to grant or restrict access to specific indexes within your vector bucket.

Key characteristics of vector buckets:

- Purpose-built for vector storage and similarity search operations.
- Strongly consistent writes ensure that the vector data is immediately accessible.
- Automatic optimization of vector data for best price-performance as datasets scale.

For more information about vector index limits per bucket and other limitations, see Limitations and restrictions.

Topics

- Vector bucket naming rules
- Creating a vector bucket
- Listing vector buckets
- Viewing vector bucket attributes
- Deleting an empty vector bucket
- Managing vector bucket policies
- Using tags with S3 vector buckets

Vector bucket naming rules

Vector bucket names must follow specific naming conventions to ensure uniqueness within an AWS Region. Amazon S3 enforces the following bucket naming requirements, and you can't create a vector bucket if these rules aren't followed. Additionally, there are best practices that, while not enforced, help prevent conflicts when working with vector buckets programmatically or through the console.

Vector bucket naming requirements

When creating vector buckets, you must follow these requirements:

- Vector bucket names must be unique in the same AWS account for each AWS Region.
- Vector bucket names must be between 3 and 63 characters long.
- Vector bucket names can consist only of lowercase letters (a-z), numbers (0-9), and hyphens (-).
- Vector bucket names must begin and end with a letter or number.

Best practices for naming

We recommend following these best practices when naming your vector buckets:

- Use descriptive names that reflect the purpose of your vector data (for example, product-recommendations, document-embeddings).
- Avoid using sensitive information in bucket names as they may appear in logs and URLs.
- Keep names concise but meaningful for easier management and identification.

These naming conventions ensure that your vector buckets can be reliably accessed through the AWS Management Console, Amazon S3 REST API, the AWS CLI, and AWS SDKs.

Creating a vector bucket

You can create a vector bucket using the S3 console or the AWS CLI. All data stored in vector buckets are always encrypted at rest. By default, vector buckets use SSE-S3 to encrypt vector data. You can choose to configure buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) instead. The bucket encryption settings can’t be changed after a vector bucket is created, so it's important to choose the appropriate encryption method based on

your security requirements and compliance needs. For more information about security in vector buckets, see Data protection and encryption in S3 Vectors.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. Choose **Create vector bucket**.
4. For **Vector bucket name**, enter a name for your bucket.

   The bucket name must follow the naming rules:

   - Bucket name must be between 3 and 63 characters long.
   - Bucket name can only include lowercase letters, numbers, and hyphens.
   - Bucket name must be unique within your AWS account for an AWS Region.

   For more information about vector bucket naming rules, see Vector bucket naming rules.

   > **Important**
   >
   > You can't change the vector bucket name after you create the bucket.

5. For **Encryption**, choose one of the following options:

   - **Don't specify encryption type** – Amazon S3 automatically applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for new vectors. Choose this option for the simplest setup with no additional configuration.
   - **Specify encryption type** – Choose a specific encryption method:
     - **Server-side encryption with Amazon S3 managed keys (SSE-S3)** – Explicitly choose to use SSE-S3. Amazon S3 encrypts your vector data as it writes it to storage and decrypts it when you access it. AWS manages all encryption keys automatically.
     - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** – Uses customer managed keys (CMKs) in AWS KMS, giving you more control over your encryption keys, key rotation, and access policies.

       If you select SSE-KMS, you have additional options:

- **Choose from your AWS KMS keys** – Select an existing customer managed key from your account.
- **Enter AWS KMS key ARN** – Specify the full ARN of a KMS key (required format).
- **Create a KMS key** – Opens the AWS KMS console to create a new customer managed key.

KMS key requirements:

- The KMS key must be in the same Region as the vector bucket.
- You must specify the full KMS key ARN (key IDs and aliases aren't supported).
- You must grant the S3 Vectors service principal (`indexing.s3vectors.amazonaws.com`) the `kms:Decrypt` permission to use the key. For more information about an example AWS KMS key policy, see Data protection and encryption in S3 Vectors.

For detailed information about encryption options and KMS key setup, see Using SSE-KMS encryption.

> **Important**
>
> Encryption settings can't be changed after the vector bucket is created. Choose carefully based on your long-term security and compliance requirements.

6. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see Using tags with S3 vector buckets.
7. Choose **Create vector bucket**.

After creation, you'll see a confirmation message. The new vector bucket appears in your vector buckets list and is ready for creating vector indexes within the bucket.

Using the AWS CLI

You can create a vector bucket with SSE-S3 encryption using the following command. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3vectors create-vector-bucket \
   --vector-bucket-name "amzn-s3-demo-vector-bucket"
```

To create a vector bucket with SSE-KMS encryption using a customer managed KMS key:

```
aws s3vectors create-vector-bucket \
   --vector-bucket-name "amzn-s3-demo-vector-bucket" \
   --encryption-configuration '{"sseType": "aws:kms", "kmsKeyArn": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"}'
```

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Create a vector bucket
s3vectors.create_vector_bucket(vectorBucketName="media-embeddings")
```

Listing vector buckets

You can view all your vector buckets using the Amazon S3 console, AWS CLI, or AWS SDKs. The listing operations support prefix-based filtering to help you find specific buckets when you have many vector buckets in your account. For more information about `ListVectorBuckets`, prefix limits, and response limits, see ListVectorBuckets in the *Amazon S3 API Reference*.

Prefix search capability

Prefix search allows you to list buckets that start with a specific prefix, making it easier to organize and find related vector buckets. This is particularly useful when you use naming conventions that group related buckets together:

- **Environment-based**: `production-vectors-`, `staging-vectors-`, `dev-vectors-`
- **Use case-based**: `ml-model-vectors-`, `document-search-`, `image-similarity-`
- **Team-based**: `data-science-vectors-`, `ml-platform-vectors-`

Using the S3 console

To list vector buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.

   The console displays a list of all your vector buckets with the following information:

   - **Name** – The unique name of the vector bucket
   - **Creation date** – When the bucket was created
   - **Amazon Resource Name (ARN)** – The full ARN for programmatic access

To filter the list:

- To find a bucket based on the start of the bucket name, enter a vector bucket name or prefix in the search box above the bucket list.
- Use prefixes to find groups of related buckets (for example, type "prod-" to find all production buckets)

  The list updates in real-time as you type

Using the AWS CLI

```
aws s3vectors list-vector-buckets
```

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vector buckets
response = s3vectors.list_vector_buckets()
buckets = response["vectorBuckets"]
```

```
print(buckets)
```

Viewing vector bucket attributes

You can view detailed information about a vector bucket, including its properties, encryption settings and creation details using the Amazon S3 REST API, AWS SDKs, S3 Console, or the AWS Command Line Interface (AWS CLI). For more information about `GetVectorBucket`, see GetVectorBucket in the *Amazon S3 API Reference*.

Using the S3 console

1. Sign in to the console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. The console displays a list of all your vector buckets. Find a bucket based on the start of the bucket name, enter a vector bucket name or prefix in the search box above the bucket list. Once you locate your vector bucket, you can view detailed information about it, including its encryption settings, tags, default index mode for new vector indexes, and creation details in the **Properties** tab.

Using the AWS CLI

```
aws s3vectors get-vector-bucket --vector-bucket-name "amzn-s3-demo-vector-bucket"
```

Deleting an empty vector bucket

You can delete a vector bucket when you no longer need it. To delete a vector bucket, you must first delete all the vector indexes within the bucket. When you delete a vector index, all vector data within it is deleted. Use the Amazon S3 REST API, AWS SDKs, S3 Console, or the AWS Command Line Interface (AWS CLI) to delete a vector bucket.

Before you can delete a vector bucket, you must:

- Delete all vector indexes in the bucket.
- Ensure no operations are in progress on the bucket or its indexes.

Important

- Bucket deletion is permanent and can't be undone.
- All data and configuration associated with the bucket is permanently lost.
- The bucket name becomes available for reuse after deletion.
- Any applications or scripts referencing the bucket will receive errors after deletion.

Using the S3 console

1. Sign in to the console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. The console displays a list of all your vector buckets. Find a bucket based on the start of the bucket name, enter a vector bucket name or prefix in the search box above the bucket list. Once you locate and choose your vector bucket, select the **Delete** option.
4. To confirm this deletion, type **`delete`** and then select **Delete vector bucket**.

Using the AWS CLI

First, check that no vector indexes exist in the bucket. For more information about how to verify the bucket is empty, see Listing vector indexes.

If indexes exist, you must delete all vectors from each index and then delete the indexes. For more information about how to verify the bucket is empty, see Listing vectors, Deleting vectors from a vector index, and Deleting a vector index.

To delete the empty vector bucket, use the following example command and replace the *`user input placeholders`* with your own information.

```
aws s3vectors delete-vector-bucket \
  --vector-bucket-name "amzn-s3-demo-vector-bucket"
```

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Delete a vector bucket
response = s3vectors.delete_vector_bucket(vectorBucketName="media-embeddings")
```

Managing vector bucket policies

Vector bucket policies are resource-based policies that you attach directly to vector buckets to control access to the bucket and its contents. You can add, view, edit, delete vector bucket policies by using the Amazon S3 REST API, AWS SDKs, S3 Console, or the AWS Command Line Interface (AWS CLI). Bucket policies for vector buckets can grant permissions to principals from other AWS accounts, making them useful for cross-account access scenarios.

Policy management operations

- PutVectorBucketPolicy – Add or update a bucket policy.
- GetVectorBucketPolicy – Retrieve the current bucket policy.
- DeleteVectorBucketPolicy – Remove the bucket policy.

Adding a vector bucket policy

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Vector buckets** and select the vector bucket name that you want to add a policy to.
4. Choose the **Permissions** tab.
5. Under **Vector bucket policy**, choose **Edit**.
6. In the policy editor, enter your policy JSON.

7. (Optional) Choose **Policy examples** to see sample policies that you can adapt to your needs.
8. After entering your policy, choose **Save changes**.

Using the AWS CLI

To add or update a bucket policy, use the following example command and replace the *user input placeholders* with your own information.

```
aws s3vectors put-vector-bucket-policy \
  --vector-bucket-name "amzn-s3-demo-vector-bucket" \
  --policy '{"Version": "2012-10-17",       "Statement":[{"Effect":"Allow","Principal":
{"AWS":"arn:aws:iam::111122223333:root"},"Action":"s3vectors:*","Resource":"arn:aws:s3vectors:a
region:111122223333:bucket/amzn-s3-demo-vector-bucket"}]}'
```

Viewing a vector bucket policy

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Amazon S3**.
3. Choose **Vector buckets** and select the vector bucket name that you want to view the policy for.
4. Choose the **Permissions** tab.

Using the AWS CLI

To retrieve a bucket policy, use the following example command and replace the *user input placeholders* with your own information.

```
aws s3vectors get-vector-bucket-policy \
  --vector-bucket-name "amzn-s3-demo-vector-bucket"
```

Deleting a vector bucket policy

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Amazon S3**.

3. Choose **Vector buckets** and select the vector bucket name that you want to delete the policy for.
4. Choose the **Permissions** tab.
5. Under the **Vector bucket policy**, choose **Delete**.

Using the AWS CLI

To delete a bucket policy, use the following example command and replace the *`user input placeholders`* with your own information.

```
aws s3vectors delete-vector-bucket-policy \
  --vector-bucket-name "amzn-s3-demo-vector-bucket"
```

For detailed information about creating and managing bucket policies, including policy examples and best practices, see S3 Vectors resource-based policy examples.

Using tags with S3 vector buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector buckets. You can tag S3 vector buckets when you create them or manage tags on existing vector buckets. For general information about tags, see Tagging for cost allocation or attribute-based access control (ABAC).

> **Note**
>
> There is no additional charge for using tags on vector buckets beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

Common ways to use tags with vector buckets

Use tags on your S3 vector buckets for:

- **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 vector buckets based on their tags. For more information, see Using tags for attribute-based access control (ABAC).

ABAC for S3 vector buckets

Amazon S3 vector buckets support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 vector bucket policies. For enterprises, ABAC inAmazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 vector buckets based on the vector bucket's tags by using the following global condition keys:

`aws:ResourceTag/key-name`

Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `Dept` with the value `Marketing`. For more information, see Controlling access to AWS resources.

`aws:RequestTag/key-name`

Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `Dept` and that it has the value `Accounting`. For more information, see Controlling access during AWS requests. You can use this condition key to restrict which tag key-value pairs can be passed during the `TagResource` and `CreateVectorBucket` API operations.

`aws:TagKeys`

Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see Controlling access based on tag keys. You can create an S3 vector bucket with tags. To allow tagging during the `CreateVectorBucket` API operation, you must create a policy that includes both the `s3vectors:TagResource` and `s3vectors:CreateVectorBucket` actions. You can then use the `aws:TagKeys` condition key to enforce using specific tags in the `CreateVectorBucket` request.

`s3vectors:VectorBucketTag/tag-key`

Use this condition key to grant permissions to specific data in vector buckets using tags. This condition key acts on the tags assigned to the vector bucket for all S3 Vectors actions. Even when you create a index with tags, this condition key acts on the tags applied to the vector bucket that contains that index. For example, you could require that access to a bucket is allowed only if the bucket has the attached tag key `Dept` with the value `Marketing`. When

accessing indexes, this condition references tags associated with the vector bucket containing that index, while the `aws:ResourceTag/tag-key` will reference the tags of the index itself.

Example ABAC policies for vector buckets

See the following example ABAC policies for Amazon S3 vector buckets.

1.1 - IAM policy to create or modify vector buckets with specific tags

In this IAM policy, users or roles with this policy can only create S3 vector buckets if they tag the vector bucket with the tag key `project` and tag value `Trinity` in the vector bucket creation request. They can also add or modify tags on existing S3 vector buckets as long as the `TagResource` request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the vector buckets or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateVectorBucketWithTags",
      "Effect": "Allow",
      "Action": [
        "s3vectors:CreateVectorBucket",
        "s3vectors:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": [
            "Trinity"
          ]
        }
      }
    }
  ]
}
```

1.2 - Vector bucket policy to restrict operations on the vector bucket using tags

In this vector bucket policy, IAM principals (users and roles) can perform operations using the `PutVectorBucketPolicy` action on the vector bucket only if the value of the vector bucket's `project` tag matches the value of the principal's `project` tag.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowObjectOperations",
      "Effect": "Allow",
      "Principal": {
        "AWS": "111122223333"
      },
      "Action": "s3vectors:PutVectorBucketPolicy",
      "Resource": "arn:aws:s3vectors:us-west-2:111122223333:bucket/amzn-s3-demo-vector-
bucket",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        }
      }
    }
  ]
}
```

1.3 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a vector bucket only if the value of the vector bucket's `project` tag matches the value of the principal's `project` tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these vector buckets. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your vector buckets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceTaggingRulesOnModification",
      "Effect": "Allow",
      "Action": [
        "s3vectors:TagResource"
      ],
      "Resource": "arn:aws:s3vectors:us-west-2:111122223333:bucket/*",
      "Condition": {
        "StringEquals": {
```

```
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "project",
            "environment",
            "owner",
            "cost-center"
          ]
        }
      }
    }
  ]
}
```

1.4 - Using the `s3vectors:VectorBucketTag` condition key

In this IAM policy, the condition statement allows access to the vector bucket's and vector index's operations only if the vector bucket has the tag key `Environment` and tag value `Production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToTaggedBucket",
      "Effect": "Allow",
      "Action": "*",
      "Resource": "arn:aws:s3vectors:us-west-2:111122223333:bucket/*",
      "Condition": {
        "StringEquals": {
          "s3vectors:VectorBucketTag/Environment": "Production"
        }
      }
    }
  ]
}
```

Managing tags for vector buckets

You can add or manage tags for S3 vector buckets using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or using the S3 APIs: TagResource, UntagResource, and ListTagsForResource. For more information, see:

Creating vector buckets with tags

You can tag Amazon S3 vector buckets when you create them. There is no additional charge for using tags on vector buckets beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging vector buckets, see Using tags with S3 vector buckets.

Permissions

To create a vector bucket with tags, you must have the following permissions:

- `s3vectors:CreateVectorBucket`
- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a vector bucket with tags, you can do the following:

- Verify that you have the required Permissions to create the vector bucket and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your vector buckets only with specific tag keys and values. For more information, see Using tags for attribute-based access control (ABAC).

Steps

You can create a vector bucket with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a vector bucket with tags using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **vector buckets**.
3. Choose **create vector bucket** to create a new vector bucket.
4. Create a vector bucket as you normally would; see Creating a vector bucket.

5. On the **Create vector bucket** page, **Tags** is an option when creating a new vector bucket.
6. Enter a name for the vector bucket.
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new vector bucket, choose **Create vector bucket**.

Using the REST API

For information about the Amazon S3 REST API support for creating a vector bucket with tags, see the following section in the *Amazon S3 Vectors API Reference*:

CreateVectorBucket

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a vector bucket with tags by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

When you create a vector bucket you must provide configuration details and use the following naming convention: `example-vector-bucket`

```
aws s3vector create-vector-bucket --vector-bucket-name acc-bucket \
  --tags Department=Accounting,Stage=Prod
```

Adding a tag to a vector bucket

You can add tags to Amazon S3 vector buckets and modify these tags. There is no additional charge for using tags on vector buckets beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging vector buckets, see Using tags with S3 vector buckets.

Permissions

To add a tag to a vector bucket, you must have the following permission:

- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a vector bucket, you can do the following:

- Verify that you have the required Permissions to add a tag to a vector bucket.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to vector buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWSSDKs.

Using the S3 console

To add tags to a vector bucket using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **vector buckets**.
3. Choose the vector bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a vector bucket, see the following section in the *Amazon S3 Vectors API Reference*:

TagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a vector bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

```
aws s3vectors tag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket \
--tags Stage=Prod,CostCenter=Marketing
```

Viewing vector bucket tags

You can view or list tags applied to Amazon S3 vector buckets. For more information about tagging vector buckets, see Using tags with S3 vector buckets.

Permissions

To view tags applied to a vector bucket, you must have the following permission:

- `s3vectors:ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a vector bucket, you can do the following:

- Verify that you have the required Permissions to view or list the tags of the vector bucket.

Steps

You can view tags applied to vector buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a vector bucket using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **vector buckets**.
3. Choose the vector bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the vector bucket.
6. The **Tags** section shows the User-defined tags by default. You can select the AWS-generated tags tab to view tags applied to your vector bucket by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a vector bucket, see the following section in the Amazon Simple Vectors API Reference:

ListTagsforResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a vector bucket. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3vectors list-tags-for-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket
```

Deleting a tag from a vector bucket

You can remove tags from S3 vector buckets. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector buckets. For more information about tagging vector buckets, see Using tags with S3 vector buckets.

> **Note**
>
> If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the vector bucket.

Permissions

To delete a tag from a vector bucket, you must have the following permission:

- `s3vectors:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a vector bucket, you can do the following:

- Verify that you have the required Permissions to delete a tag from a vector bucket.

Steps

You can delete tags from vector buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a vector bucket using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **vector buckets**.
3. Choose the vector bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a vector bucket, see the following section in the *Amazon S3 Vectors API Reference*:

UntagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a vector bucket by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3vectors untag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket \
--tag-keys CostCenter Department
```

Vector indexes

> **Note**
>
> Choose your vector index configuration parameters carefully. After you create a vector index, you can't update the vector index name, dimension, distance metric, or non-filterable metadata keys. To change any of these values, you must create a new vector index.

Vector indexes are resources within vector buckets that store and organize vector data for efficient similarity search operations. When you create a vector index, you specify the distance metric (`Cosine` or `Euclidean`), the number of dimensions that a vector should have, and optionally a list of metadata fields that you want to exclude from filtering during similarity queries.

For more information about vector index limits per bucket, vector limits per index, and dimension limits per vector, see Limitations and restrictions.

Each vector index has a unique Amazon Resource Name (ARN). The ARNs of vector indexes follow the following format:

```
arn:aws:s3vectors:region:account-id:bucket/bucket-name/index/index-name
```

Vector index naming requirements

- Vector index names must be unique within the vector bucket.
- Vector index names must be between 3 and 63 characters long.
- Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.).

- Vector index names must begin and end with a letter or number.

Dimension requirements

A dimension is the number of values in a vector. All vectors added to the index must have exactly this number of values.

- A dimension must be an integer between 1 and 4096.
- A larger dimension requires more storage space.

Distance metric options

Distance metric specifies how similarity between vectors is calculated. When creating vector embeddings, choose your embedding model's recommended distance metric for more accurate results.

- **Cosine** – Measures the cosine of the angle between vectors. Best for normalized vectors and when direction matters more than magnitude.
- **Euclidean** – Measures the straight-line distance between vectors. Best when both direction and magnitude are important.

Non-filterable metadata keys

Metadata keys allow you to attach additional information to your vectors as key-value pairs during storage and retrieval. By default, all metadata is filterable, so you can use it to filter query results. However, you can designate specific metadata keys as non-filterable when you want to store information with vectors without using it for filtering.

Unlike default metadata keys, these keys can't be used as query filters. Non-filterable metadata keys can be retrieved but can't be searched, queried, or filtered. You can only access it after finding the index.

Non-filterable metadata keys allow you to enrich vectors with additional context that you want to retrieve with search results but don't need for filtering. A common example of a non-filterable metadata key is when you embed text into vectors and want to include the original text itself as non-filterable metadata. This allows you to return the source text alongside vector search results without increasing your filterable metadata size limits. Other examples include storing creation

timestamps, source URLs, or descriptive information purely for reference. Non-filterable metadata keys can be accessed when retrieving vectors but, unlike default metadata keys, these keys can't be used as query filters.

Requirements for non-filterable metadata keys are as follows.

- Non-filterable metadata keys must be unique within the vector index.
- Non-filterable metadata keys must be 1 to 63 characters long.
- Non-filterable metadata keys can't be modified after the vector index is created.
- S3 Vectors support up to 10 non-filterable metadata keys per index.

For more information about non-filterable metadata keys, see Non-filterable metadata.

Index mode

Each vector index has an index mode, which determines the query capabilities the index supports. The modes are `ENHANCED` and `CLASSIC`. We recommend `ENHANCED` for almost all workloads, because it gives you higher recall on filtered queries and additional filter operators. For what each mode supports, see Metadata filtering.

A new vector index inherits the default index mode of the vector bucket that contains it. A vector bucket created on or after September 30, 2026 has a default index mode of `ENHANCED`, and indexes in it cannot use `CLASSIC`. A vector bucket created before that date has a default index mode of `CLASSIC`, so that indexes you already had are unchanged and indexes you create in it later behave consistently with them.

You can read an index's mode with GetIndex and change it with UpdateIndexMode. You can read a bucket's default with GetVectorBucket and change it with PutVectorBucketDefaultIndexMode, which applies to indexes you create afterward. To move an existing index, see Changing a vector index's mode.

Topics

- Creating a vector index in a vector bucket
- Changing a vector index's mode
- Listing vector indexes
- Deleting a vector index
- Using tags with S3 vector indexes

Creating a vector index in a vector bucket

> **Note**
>
> Choose your vector index configuration parameters carefully. After you create a vector index, you can't update the vector index name, dimension, distance metric, or non-filterable metadata keys. To change any of these values, you must create a new vector index.

A vector index is a resource within a vector bucket that stores and organizes vector data for efficient similarity search. When you create a vector index, you define the characteristics that all vectors in that index must share, such as the dimension, the distance metric used for similarity calculations, and optionally non-filterable metadata keys. You can also optionally configure dedicated encryption settings and tags for the vector index at the time of index creation. For more information about vector index naming requirements, dimension requirements, distance metric options, and non-filterable metadata keys, see Limitations and restrictions. For more information about setting encryption configuration for vector indexes, see Data protection and encryption in S3 Vectors. For more information about setting tags, see Using tags with S3 vector buckets.

Vector indexes must be created within an existing vector bucket and require specific configuration parameters that can't be modified after creation.

Using the S3 console

To create a vector index

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket where you want to create a vector index.
4. Choose **Create vector index**.
5. For **Vector index name**, enter a name for your vector index.

   Vector index names must be unique within the vector bucket. Index name must be between 3 and 63 characters. Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.). For more information about the vector index naming requirements, see Limitations and restrictions.
6. For **Dimension**, enter the number of values in each vector.

> **Note**
>
> - The value for **Dimension** determines how many numerical values each vector will contain.
> - All vectors added to this index must have exactly this number of values.
> - Dimension must be between 1 and 4096.
> - A larger dimension requires more storage space.
> - Choose based on your embedding model's output dimensions.

For more information about the dimension requirements, see Limitations and restrictions.

7. For **Distance metric**, choose one of the following options:
   - **Cosine** – Measures the cosine of the angle between vectors. Best for normalized vectors and when direction matters more than magnitude
   - **Euclidean** – Measures the straight-line distance between vectors. Best when both direction and magnitude are important.
8. (Optional) Under **Non-filterable metadata**, configure metadata keys that will be stored but not used for filtering:

   To add non-filterable metadata keys:

   a. Choose **Add key**.

   b. Enter a key name (1-63 characters and unique within this vector index).

   c. Repeat to add additional keys (maximum 10 keys).

   > **Note**
   >
   > You can attach filterable metadata as key-value pairs to each vector when you insert vector data after you create a vector index. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata keys that are specified as non-filterable during vector index creation are excluded from filtering. For more information about metadata size limits per vector, including both total and filterable metadata constraints, see Limitations and restrictions.

9. Review your configuration carefully.

> **Note**
>
> These settings can't be changed after creation.

10. Under **Encryption**, choose **Specify encryption type**. You have the option to **Use bucket settings for encryption** or override the encryption settings for the vector index. If you override the bucket-level settings, you have the option to specify encryption type for the vector index as **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or the **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. For more information about setting encryption configuration for vector indexes, see Data protection and encryption in S3 Vectors.
11. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see Using tags with S3 vector buckets.
12. Choose **Create vector index**.

Using the AWS CLI

To create a vector index in a vector bucket, use the following example commands and replace the `user input placeholders` with your own information.

Example 1: Creating a vector index with non-filterable metadata keys

```
aws s3vectors create-index \
  --vector-bucket-name "amzn-s3-demo-vector-bucket" \
  --index-name "idx" \
  --data-type "float32" \
  --dimension 1 \
  --distance-metric "cosine" \
  --metadata-configuration '{"nonFilterableMetadataKeys":["nonFilterableKey1"]}'
```

Example 2: Creating a vector index without non-filterable metadata keys

```
aws s3vectors create-index \
  --vector-bucket-name "amzn-s3-demo-vector-bucket" \
```

```
  --index-name "idx2" \
  --data-type "float32" \
  --dimension 4096 \
  --distance-metric "euclidean"
```

In addition, all metadata (both filterable and non-filterable) is retrieved the same way by using the `GetVectors`, `ListVectors`, or `QueryVectors` API operations. The following CLI command shows how to retrieve vectors with metadata (including non-filterable metadata).

Example request:

```
aws s3vectors get-vectors \
  --vector-bucket-name "amzn-s3-demo-vector-bucket" \
  --index-name "idx" \
  --keys '["vec1", "vec3"]' \
  --return-data \
  --return-metadata \
```

Example response:

```
{
    "vectors": [
        {
            "key": "vec1",
            "data": {
                "float32": [
                    0.10000000149011612,
                    0.20000000298023224,
                    0.30000001192092896,
                    0.4000000059604645,
                    0.5
                ]
            },
            "metadata": {
                "category": "test",
                "text": "First vector"
            }
        },
        {
            "key": "vec3",
            "data": {
```

```
                "float32": [
                    0.6000000238418579,
                    0.699999988079071,
                    0.800000011920929,
                    0.8999999761581421,
                    1.0
                ]
            },
            "metadata": {
                "text": "Third vector",
                "category": "test"
            }
        }
    ]
}
```

The response will include all metadata associated with the vector, regardless of whether it was specified as filterable or non-filterable during index creation.

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Create a vector index "movies" in the vector bucket "media-embeddings" without non-
filterable metadata keys
s3vectors.create_index(
    vectorBucketName="media-embeddings",
    indexName="movies",
    dimension=3,
    distanceMetric="cosine",
    dataType = "float32"
)

#Create a vector index "movies" in the vector bucket "media-embeddings" with non-
filterable metadata keys
s3vectors.create_index(
    vectorBucketName="media-embeddings",
```

```
    indexName="movies",
    dimension=3,
    distanceMetric="cosine",
    dataType = "float32",
    metadataConfiguration= {"nonFilterableMetadataKeys":
 ["nonFilterableMetadataKey1"]}
)
```

Changing a vector index's mode

A vector index whose index mode is ENHANCED applies your metadata filter before the vector search, ensuring high recall even when filters match a small fraction of vectors, and it supports the `$startsWith` filter operator. Indexes in vector buckets created before September 30, 2026 use CLASSIC by default, including indexes you create in those buckets later. We recommend moving these indexes to ENHANCED.

Changing an index to ENHANCED takes effect in place, with no re-ingestion, no changes to your queries or your application, and no additional charge. To change an index's mode, call UpdateIndexMode. To see an index's current mode, call GetIndex or view the index's detail page in the Amazon S3 console.

To change an index's mode (console)

1. Sign in to the console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. Choose the vector bucket that contains the index, then choose the index.
4. Choose **Enable enhanced index mode**.
5. Review the information in the confirmation dialog, select the acknowledgement, and then choose **Enable**.

```
aws s3vectors update-index-mode --vector-bucket-name "amzn-s3-demo-vector-bucket" --
index-name "idx" --index-mode "ENHANCED"
```

Before you change an index, confirm that your queries use 100 or fewer filter constraints. On an ENHANCED index, a query that exceeds the limit returns a validation error. For how constraints are

counted, and for how to consolidate or split a query that exceeds the limit, see Filter constraints per query. For how a filter affects query latency, see Query performance with filters.

Topics

- Test an index before you change it
- Set the index mode for new indexes in a vector bucket
- Turn off the enhanced index mode

Test an index before you change it

On a `CLASSIC` index, you can set the `queryMode` parameter to `ENHANCED` on a QueryVectors request to run that query with pre-filtering while the index stays as it is. You can also set `queryMode` to `ENHANCED` on an index whose index mode is already `ENHANCED`, where it has no additional effect.

If a query uses `$startsWith` under `queryMode=ENHANCED` and you later remove `queryMode`, the request returns a validation error, because `$startsWith` requires `ENHANCED` query behavior. Update the index mode to use `$startsWith` without setting `queryMode` on every request.

Set the index mode for new indexes in a vector bucket

Each vector bucket has a default index mode, inherited by new vector indexes. Setting the default applies to indexes you create afterward, and does not change any index that already exists in the bucket. To read a bucket's default, call GetVectorBucket, or view the bucket's **Properties** tab in the Amazon S3 console.

To move a vector bucket and its indexes to `ENHANCED`, complete the following steps.

1. Set the bucket's default index mode to `ENHANCED` with PutVectorBucketDefaultIndexMode, so that vector indexes you create afterward use `ENHANCED`.
2. List the vector indexes in the bucket with ListIndexes, and call GetIndex on each one to find those whose index mode is `CLASSIC`.
3. Call UpdateIndexMode with `indexMode` set to `ENHANCED` on each of those indexes.

```
aws s3vectors put-vector-bucket-default-index-mode --vector-bucket-name "amzn-s3-demo-vector-bucket" --default-index-mode "ENHANCED"
```

Turn off the enhanced index mode

Changing an index to ENHANCED is reversible if your vector bucket was created before September 30, 2026. You can change the index back to CLASSIC with the AWS CLI, the AWS SDKs, or the Amazon S3 REST API. You cannot do this from the Amazon S3 console.

```
aws s3vectors update-index-mode --vector-bucket-name "amzn-s3-demo-vector-bucket" --
index-name "idx" --index-mode "CLASSIC"
```

On a CLASSIC index, a query with a selective filter can return fewer than top K results, and $startsWith is available only when the request sets queryMode to ENHANCED. For which indexes accept CLASSIC, see UpdateIndexMode in the *Amazon S3 API Reference*.

Listing vector indexes

You can view all vector indexes within a vector bucket. The listing operation supports prefix-based filtering to help you find specific indexes when you have many indexes in a bucket. For more information about ListIndexes, prefix limits, and response limits, see ListIndexes in the Amazon Simple Storage Service API Reference.

Prefix search capability

Prefix search allows you to list indexes that start with a specific prefix, making it easier to organize and find related vector indexes. This is particularly useful when you use naming conventions that group related indexes together:

- **By data type:** text-embeddings-, image-features-, audio-vectors-
- **By model:** model1-embeddings-, model2-vectors-, custom-model-
- **By use case:** search-index-, recommendation-, similarity-
- **By environment:** prod-vectors-, staging-vectors-, dev-vectors-

Using the S3 console

To list vector indexes

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket containing the indexes you want to view.
4. The console displays a comprehensive list of all vector indexes in the bucket, including:

   - **Name** – The name for each index.
   - **Create date** – When the index was created.
   - **Amazon Resource Name (ARN)** – Full ARN for each index.

To filter the list

1. Enter an index name or prefix in the search box above the index list. Use prefixes to find groups of related indexes.
2. The list updates in real-time as you type.

Using the AWS CLI

Use the following example commands and replace the *`user input placeholders`* with your own information.

To list indexes with a specific prefix in a vector bucket

Example request:

```
aws s3vectors list-indexes \
  --vector-bucket-name "amzn-s3-demo-bucket" \
  --prefix "idx" \
  --max-results 1
```

Example response:

```
{
    "nextToken":
 "lObb29ZkzxMGtBXs97Rkbs26xdtKemu4brsnq2jX8DCocADkILv5cRphemXS3PXXFnQBihQBmESgEeKaGA",
    "indexes": [
        {
```

```
            "vectorBucketName": "amzn-s3-demo-bucket",
            "indexName": "idx",
            "indexArn": "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-
vector-bucket/index/idx",
            "creationTime": "2025-06-12T15:50:23+00:00"
        }
    ]
}
```

To list indexes with pagination

Example request:

```
aws s3vectors list-indexes \
  --vector-bucket-name "amzn-s3-demo-bucket" \
  --prefix "idx" \
  --next-token
 "l0bb29ZkzxMGtBXs97Rkbs26xdtKemu4brsnq2jX8DCocADkILv5cRphemXS3PXXFnQBihQBmESgEeKaGA"
```

Example response:

```
{
    "indexes": [
        {
            "vectorBucketName": "amzn-s3-demo-bucket",
            "indexName": "idx2",
            "indexArn": "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-
vector-bucket/index/idx2",
            "creationTime": "2025-06-12T15:45:37+00:00"
        }
    ]
}
```

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")
```

```
#List vector indexes in your vector bucket
response = s3vectors.list_indexes(vectorBucketName="media-embeddings")
indexes = response["indexes"]
print(indexes)
```

Deleting a vector index

You can delete a vector index when you no longer need it. This operation permanently removes the index and all vectors that are stored within it.

> **Important**
>
> When you delete a vector index, you need to know the following:
>
> - You can delete vector indexes even when the indexes contain vectors.
> - All vectors stored in the index are permanently deleted
> - All metadata associated with those vectors is permanently lost
> - The operation can't be undone or reversed
> - Any ongoing operations on the index will fail immediately
> - Applications querying the index will receive errors
> - The index name becomes available for reuse within the bucket

Using the AWS CLI

Before you delete a vector index, verify the vector index. For more information about how to check the index details, see GetIndex in the *Amazon S3 API Reference*. For more information about how to list vectors inside the index to see what will be deleted, see Listing vector indexes.

To delete a vector index, use the following example commands. Replace the *`user input placeholders`* with your own information.

```
aws s3vectors delete-index --vector-bucket-name "amzn-s3-demo-vector-bucket" \
         --index-name "idx2"
```

For more information about how to verify whether the index is deleted, see Listing vector indexes.

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Delete a vector index
response = s3vectors.delete_index(
    vectorBucketName="media-embeddings",
    indexName="movies")
```

Using tags with S3 vector indexes

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector indexes. You can tag S3 vector indexes when you create them or manage tags on existing vector indexes. For general information about tags, see Tagging for cost allocation or attribute-based access control (ABAC).

> **Note**
>
> There is no additional charge for using tags on vector indexes beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

Common ways to use tags with vector indexes

Use tags on your S3 vector indexes for:

- **Cost allocation** – Track storage costs by vector index tag in AWS Billing and Cost Management. For more information, see Using tags for cost allocation.
- **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 vector indexes based on their tags. For more information, see Using tags for attribute-based access control (ABAC).

> **Note**
>
> You can use the same tags for both cost allocation and access control.

ABAC for S3 vector indexes

Amazon S3 vector indexes support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 vector index policies. For enterprises, ABAC inAmazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 vector indexes based on the vector index's tags by using the following global condition keys:

`aws:ResourceTag/key-name`

Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `Dept` with the value `Marketing`. For more information, see Controlling access to AWS resources.

`aws:RequestTag/key-name`

Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `Dept` and that it has the value `Accounting`. For more information, see Controlling access during AWS requests. You can use this condition key to restrict which tag key-value pairs can be passed during the `TagResource` and `CreateIndex` API operations.

`aws:TagKeys`

Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see Controlling access based on tag keys. You can create an S3 vector index with tags. To allow tagging during the `CreateVectorBucket` API operation, you must create a policy that includes both the `s3vectors:TagResource` and `s3vectors:CreateVectorBucket` actions. You can then use the `aws:TagKeys` condition key to enforce using specific tags in the `CreateVectorBucket` request.

Example ABAC policies for vector indexes

See the following example ABAC policies for Amazon S3 vector indexes.

1.1 - IAM policy to create or modify vector indexes with specific tags

In this IAM policy, users or roles with this policy can only create S3 vector indexes if they tag the vector index with the tag key `project` and tag value `Trinity` in the vector index creation request. They can also add or modify tags on existing S3 vector indexes as long as the `TagResource` request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the vector indexes or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateVectorIndexWithTags",
      "Effect": "Allow",
      "Action": [
        "s3vectors:CreateIndex",
        "s3vectors:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": [
            "Trinity"
          ]
        }
      }
    }
  ]
}
```

1.2 - IAM policy to modify tags on existing resources maintaining tagging governance

In this IAM policy, IAM principals (users or roles) can modify tags on a vector index only if the value of the vector index's `project` tag matches the value of the principal's `project` tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these vector indexes. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your vector indexes.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceTaggingRulesOnModification",
      "Effect": "Allow",
      "Action": [
        "s3vectors:TagResource"
      ],
      "Resource": "arn:aws:s3vectors:us-west-2:111122223333:bucket/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "project",
            "environment",
            "owner",
            "cost-center"
          ]
        }
      }
    }
  ]
}
```

Managing tags for vector indexes

You can add or manage tags for S3 vector indexes using the Amazon S3 Console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or using the S3 APIs: TagResource, UntagResource, and ListTagsForResource. For more information, see:

Topics

- Creating vector indexes with tags
- Adding a tag to a vector index
- Viewing vector index tags
- Deleting a tag from a vector index

Creating vector indexes with tags

You can tag Amazon S3 vector indexes when you create them. There is no additional charge for using tags on vector indexes beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging vector indexes, see Using tags with S3 vector indexes.

Permissions

To create a vector index with tags, you must have the following permissions:

- `s3vectors:CreateIndex`
- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create a vector index with tags, you can do the following:

- Verify that you have the required Permissions to create the vector index and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your vector indexes only with specific tag keys and values. For more information, see Using tags for attribute-based access control (ABAC).

Steps

You can create a vector index with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a vector index with tags using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **vector indexes**.
3. Choose **create vector index** to create a new vector index.
4. Create a vector index as you normally would; see Creating a vector index in a vector bucket.

5. On the **Create vector index** page, **Tags** is an option when creating a new vector index.
6. Enter a name for the vector index.
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new vector index, choose **Create vector index**.

Using the REST API

For information about the Amazon S3 REST API support for creating a vector index with tags, see the following section in the *Amazon S3 Vectors API Reference*:

CreateIndex

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a vector index with tags by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

When you create a vector index you must provide configuration details and use the following naming convention: `example-vector-index`

```
aws s3vectors create-index --vector-bucket-name acc-bucket --data-type "float32" \
 --index-name accounts-index --dimension 1024 --distance-metric euclidean \
 --tags Department=Accounting,Stage=Prod
```

Adding a tag to a vector index

You can add tags to Amazon S3 vector indexes and modify these tags. There is no additional charge for using tags on vector indexes beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging vector indexes, see Using tags with S3 vector indexes.

Permissions

To add a tag to a vector index, you must have the following permission:

- `s3vectors:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a vector index, you can do the following:

- Verify that you have the required Permissions to add a tag to a vector index.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to vector indexes by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWSSDKs.

Using the S3 console

To add tags to a vector index using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **vector indexes**.
3. Choose the vector index name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a vector index, see the following section in the *Amazon S3 Vectors API Reference*:

TagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a vector index by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3vectors tag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket/
index/accounts-index \
--tags Stage=Prod,CostCenter=Marketing
```

Viewing vector index tags

You can view or list tags applied to Amazon S3 vector indexes. For more information about tagging vector indexes, see Using tags with S3 vector indexes.

Permissions

To view tags applied to a vector index, you must have the following permission:

- `s3vectors:ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a vector index, you can do the following:

- Verify that you have the required Permissions to view or list the tags of the vector index.

Steps

You can view tags applied to vector indexes by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a vector index using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **vector indexes**.
3. Choose the vector index name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the vector index.
6. The **Tags** section shows the User-defined tags by default. You can select the AWS-generated tags tab to view tags applied to your vector index by AWS services.

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a vector index, see the following section in the Amazon Simple Vectors API Reference:

ListTagsforResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a vector index. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3vectors list-tags-for-resource \
  --resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket/
index/accounts-index
```

Deleting a tag from a vector index

You can remove tags from S3 vector indexes. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 vector indexes. For more information about tagging vector indexes, see Using tags with S3 vector indexes.

> **Note**
>
> If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the vector index.

Permissions

To delete a tag from a vector index, you must have the following permission:

- `s3vectors:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a vector index, you can do the following:

- Verify that you have the required Permissions to delete a tag from a vector index.

Steps

You can delete tags from vector indexes by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a vector index using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **vector indexes**.
3. Choose the vector index name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a vector index, see the following section in the *Amazon S3 Vectors API Reference*:

UntagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a vector index by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

```
aws s3vectors untag-resource \
--resource-arn arn:aws:s3vectors:us-east-1:012345678900:bucket/acc-bucket/
index/accounts-index \
--tag-keys CostCenter Department
```

Vectors

Each vector consists of a key, which uniquely identifies each vector in a vector index. Additionally, you can attach metadata (for example, year, author, genre, location) as key value pairs to each vector.

Vector data operations include inserting, listing, querying, and deleting vectors. To generate new vector embeddings of your unstructured data, you can use the InvokeModel API operation from Amazon Bedrock to specify the model ID of the embedding model that you want to use. Additionally, the open-source Amazon S3 Vectors Embed CLI tool provides a simplified way to generate embeddings and perform semantic searches from the command line. For more information about this open source tool that automates both vector embedding generation with Amazon Bedrock foundation models and semantic search operations within your S3 vector indexes, see Creating vector embeddings and performing semantic searches with `s3vectors-embed-cli`.

Vector concepts

Vector keys: Each vector is identified by a unique vector key within the index. Vector keys can be up to 1,024 characters long and must be unique within the vector index. Keys are case-sensitive and can contain any UTF-8 characters.

Vector dimension: A dimension is the number of values in a vector. Larger dimensions require more storage space. All vectors in an index must have the same number of dimensions, which is specified when you create the index. A dimension must be an integer between 1 and 4096.

Metadata: You can attach metadata to vectors as key-value pairs to provide additional context and enable filtering during queries. Metadata includes both filterable and non-filterable metadata keys. Filterable metadata is used for query filtering. Non-filterable metadata keys are specified during

a vector index creation and provides additional context but can't be used for filtering. Metadata supports string, number, and boolean types. For more information about filterable and non-filterable metadata, see Metadata filtering. For more information about metadata limits, including size limits per vector and maximum metadata keys per vector, see Limitations and restrictions.

- Deleting vectors from a vector index
- Metadata filtering

Inserting vectors into a vector index

You can add vectors to a vector index with the PutVectors API operation. Each vector consists of a key, which uniquely identifies each vector in a vector index. If you put a vector with a key that already exists in the index, it will overwrite the existing vector completely, which makes the previous vector no longer searchable. To maximize write throughput and optimize for costs, it's recommended that you insert vectors in large batches, up to the maximum batch size for `PutVectors`. However, for workloads that need to use smaller batches - such as when live, incoming vector data must become immediately searchable - you can achieve higher write throughput by using a higher number of concurrent `PutVectors` requests, up to the maximum allowed requests per second limit. For more information about the maximum batch size for `PutVectors`, which is the limit of vectors per `PutVectors` API call, and the maximum requests and vectors per second limit, see Limitations and restrictions. Additionally, you can attach metadata (for example, year, author, genre, location) as key-value pairs to each vector. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata keys that are specified as non-filterable during vector index creation are excluded from filtering. S3 vector indexes support string, number, boolean, and list types of metadata. For more information about the total metadata size limit per vector and the filterable metadata size limit per vector, see Limitations and restrictions. If the metadata size exceeds these limits, the `PutVectors` API operation will return a `400 Bad Request` error.

Before adding vector data to your vector index with the `PutVectors` API operation, you need to convert your raw data into vector embeddings, which are numerical representations of your content as arrays of floating-point numbers. The vector embeddings capture the semantic meaning

of your content, enabling similarity searches once they're stored in your vector index through the `PutVectors` operation. You can generate vector embeddings using various methods depending on your data type and use case. These methods include using machine learning frameworks, specialized embedding libraries, or AWS services such as Amazon Bedrock. For example, if you're using Amazon Bedrock, you can generate embeddings with the InvokeModel API operation and your preferred embedding model.

Additionally, Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow where Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data.

Furthermore, the open-source Amazon S3 Vectors Embed CLI tool provides a simplified way to generate embeddings and perform semantic searches from the command line. For more information about this open source tool that automates both vector embedding generation with Amazon Bedrock foundation models and semantic search operations within your S3 vector indexes, see Creating vector embeddings and performing semantic searches with `s3vectors-embed-cli`.

Note

When inserting vector data into your vector index, you must provide the vector data as `float32` (32-bit floating point) values. If you pass higher-precision values to an AWS SDK, S3 Vectors converts the values to 32-bit floating point before storing them, and GetVectors, ListVectors, and QueryVectors operations return the `float32` values. Different AWS SDKs may have different default numeric types, so ensure your vectors are properly formatted as `float32` values regardless of which SDK you're using. For example, in Python, use `numpy.float32` or explicitly cast your values.

Using the AWS SDKs

SDK for Python (Boto3)

```
# Populate a vector index with embeddings from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
```

```
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Texts to convert to embeddings.
texts = [
    "Star Wars: A farm boy joins rebels to fight an evil empire in space",
    "Jurassic Park: Scientists create dinosaurs in a theme park that goes wrong",
    "Finding Nemo: A father fish searches the ocean to find his lost son"
]

# Generate vector embeddings.
embeddings = []
for text in texts:
    response = bedrock.invoke_model(
        modelId="amazon.titan-embed-text-v2:0",
        body=json.dumps({"inputText": text})
    )

    # Extract embedding from response.
    response_body = json.loads(response["body"].read())
    embeddings.append(response_body["embedding"])

# Write embeddings into vector index with metadata.
s3vectors.put_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    vectors=[
        {
            "key": "Star Wars",
            "data": {"float32": embeddings[0]},
            "metadata": {"source_text": texts[0], "genre":"scifi"}
        },
        {
            "key": "Jurassic Park",
            "data": {"float32": embeddings[1]},
            "metadata": {"source_text": texts[1], "genre":"scifi"}
        },
        {
            "key": "Finding Nemo",
            "data": {"float32": embeddings[2]},
            "metadata": {"source_text": texts[2], "genre":"family"}
        }
    ]
```

```
)
```

Listing vectors

You can list vectors in a vector index with the ListVectors API operation. For more information about the maximum number of vectors that can be returned per page, see Limitations and restrictions. The response includes a pagination token when results are truncated. For more information about the response elements of `ListVectors`, see ListVectors in the *Amazon S3 API Reference*. You can also use `ListVectors` to export vector data from a specified vector index. `ListVectors` is strongly consistent. After a WRITE operation, you can immediately list vectors with all changes reflected.

Using the AWS CLI

To list vectors, use the following example commands. Replace the *`user input placeholders`* with your own information.

The `segment-count` and `segment-index` parameters allow you to partition your listing operations across multiple parallel requests. When you specify a `segment-count` value (such as 2), you divide the index into that many segments. The `segment-index` parameter (starting from 0) determines which segment to list. This approach helps improve performance when listing large vector indexes by enabling parallel processing. For more information about `segment-count` and `segment-index`, see ListVectors in the *Amazon S3 API Reference*.

To list all vectors in an index

Example request:

```
aws s3vectors list-vectors \
  --vector-bucket-name "amzn-s3-demo-vector-bucket" \
  --index-name "idx" \
  --segment-count 2 \
  --segment-index 0 \
  --return-data \
  --return-metadata
```

Example response:

```
{
    "vectors": [
```

```
        {
            "key": "vec3",
            "data": {
                "float32": [0.4000000059604645]
            },
            "metadata": {
                "nonFilterableKey": "val4",
                "filterableKey": "val2"
            }
        }
    ]
}
```

To list vectors with pagination

Example request:

```
aws s3vectors list-vectors \
  --vector-bucket-name "amzn-s3-demo-vector-bucket" \
  --index-name "idx" \
  --segment-count 2 \
  --segment-index 0 \
  --return-data \
  --return-metadata \
  --next-token
 "zWfh7e57H2jBfBtRRmC7OfMwl209G9dg3j2qM6kM4t0rps6ClYzJykgMOil9eGqU5nhf_gTq53IfoUdTnsg"
```

Example response:

```
{
    "vectors": [
        {
            "key": "vec1",
            "data": {
                "float32": [0.5]
            },
            "metadata": {
                "nonFilterableKey": "val2",
                "filterableKey": "val1"
            }
        }
    ]
}
```

Using the AWS SDKs

SDK for Python (Boto3)

Example: List vectors in a vector index

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vectors in your vector index

response = s3vectors.list_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    maxResults = 600,
    returnData = True,
    returnMetadata = True
)

vectors = response["vectors"]

print(vectors)
```

Example: List all vectors in a vector index in parallel

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#List vectors in the 1st half of vectors in the index.
response = s3vectors.list_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    segmentCount=2,
    segmentIndex=1,
    maxResults = 600,
    returnData = True,
    returnMetadata = True
)
```

```
vectors = response["vectors"]

#List vectors starting from the 2nd half of vectors in the index.
# This can be ran in parallel with the first `list_vectors` call.
response = s3vectors.list_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    segmentCount=2,
    segmentIndex=1,
    maxResults = 600,
    returnData = True,
    returnMetadata = True
)

vectors = response["vectors"]

print(vectors)
```

Querying vectors

You can run a similarity query with the QueryVectors API operation, where you specify the query vector, the number of relevant results to return (the top K nearest neighbors), and the index ARN. Additionally, you can use metadata filters in a query, to search only the vectors that match the filter. If you make a request to filter on a non-filterable metadata field, the request will return a `400 Bad Request` error. On `CLASSIC` indexes, you can set the optional `queryMode` parameter to run a single query with `ENHANCED` behavior without changing the index. If you don't specify `queryMode`, the query uses the index's own index mode. For more information about metadata filtering, see Metadata filtering.

In the response, the vector keys are returned by default. You can optionally include the distance and metadata in the response. When `topK` exceeds the page size, results are returned across multiple pages. The response includes a `nextToken` that you use to retrieve the next page. Continue making `QueryVectors` requests with the same `queryVector`, `topK`, `filter`, and `queryMode` parameters, passing the `nextToken` from each response, until `nextToken` is no longer present. Alternatively, you can use the built-in paginators in the AWS SDKs to automatically iterate through all pages without manually handling `nextToken`. Pagination tokens remain valid for several minutes after the query is executed. If a pagination token expires, re-issue the original query to start a new session. Writes to the vector index between page retrievals will not

be reflected in that query session. For specific limits on `topK` and page size, see Limitations and restrictions.

When generating the query vector, you should use the same vector embedding model that was used to generate the initial vectors that are stored in the vector index. For example, if you use the Amazon Titan Text Embeddings V2 model in Amazon Bedrock to generate vector embeddings of your documents, use the same embedding model to convert a question to a query vector. Additionally, Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow where Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data. For more information about how to query vectors from an Amazon Bedrock knowledge base in the console, see (Optional) Integrate S3 Vectors with Amazon Bedrock Knowledge Bases.

Furthermore, the open-source Amazon S3 Vectors Embed CLI tool provides a simplified way to perform semantic searches from the command line. This open source tool streamlines the query process by handling both the vector embedding generation with Amazon Bedrock foundation models and executing semantic search operations against your S3 vector indexes. For more information about using this tool for querying your vector data, see Creating vector embeddings and performing semantic searches with `s3vectors-embed-cli`.

S3 Vectors delivers sub-second response times for cold queries, leveraging Amazon S3 elastic throughput to efficiently search across billions of vectors. This makes it highly cost-effective for workloads with infrequent queries. For warm queries, S3 Vectors can deliver response times as low as 100ms, benefiting workloads with repeated or frequent query patterns. When query results are returned across multiple pages, subsequent pages can be accessed immediately. On a filtered query, response time also varies with the work your filter does; see Query performance with filters.

For performing similarity queries for your vector embeddings, several factors can affect average recall performance, including the vector embedding model, the size of the vector dataset (the number of vectors and dimensions), and the distribution of queries. S3 Vectors delivers 90%+ average recall for most datasets. Average recall measures the quality of query results. A 90% average recall means that the response contains 90% of the actual closest vectors (ground truth) that are stored in the vector index relative to the query vector. On a filtered query, recall also depends on how selective your filter is and on the vector index's index mode. An index whose mode is `ENHANCED` applies your filter before the search and only searches vectors that match it, ensuring high recall even when few vectors match. If your filtered queries return fewer results than you

expect, check the index's mode with GetIndex, and see Changing a vector index's mode. However, because actual performance may vary depending on your specific use cases, we recommend conducting your own tests with representative data and queries to validate that S3 Vectors meet your recall requirements.

Using the AWS SDKs

SDK for Python (Boto3)

```
# Query a vector index with an embedding from Amazon Titan Text Embeddings V2.
import boto3
import json

# Create Bedrock Runtime and S3 Vectors clients in the AWS Region of your choice.
bedrock = boto3.client("bedrock-runtime", region_name="us-west-2")
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

# Query text to convert to an embedding.
input_text = "adventures in space"

# Generate the vector embedding.
response = bedrock.invoke_model(
    modelId="amazon.titan-embed-text-v2:0",
    body=json.dumps({"inputText": input_text})
)

# Extract embedding from response.
model_response = json.loads(response["body"].read())
embedding = model_response["embedding"]

# Query vector index.
response = s3vectors.query_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))

# Query vector index with a metadata filter.
response = s3vectors.query_vectors(
```

```
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=3,
    filter={"genre": "scifi"},
    returnDistance=True,
    returnMetadata=True
)
print(json.dumps(response["vectors"], indent=2))

# Paginated query with manual nextToken handling.
query_params = dict(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=500,
    returnDistance=True,
    returnMetadata=True,
)
response = s3vectors.query_vectors(**query_params)
for vector in response["vectors"]:
    print(vector)
while response.get("nextToken") is not None:
    response = s3vectors.query_vectors(**query_params,
 nextToken=response["nextToken"])
    for vector in response["vectors"]:
        print(vector)

# Use the built-in paginator to automatically iterate through all pages.
paginator = s3vectors.get_paginator("query_vectors")

for page in paginator.paginate(
    vectorBucketName="media-embeddings",
    indexName="movies",
    queryVector={"float32": embedding},
    topK=500,
    returnDistance=True,
    returnMetadata=True,
):
    for vector in page["vectors"]:
        print(vector)
```

Deleting vectors from a vector index

You can delete specific vectors from a vector index by specifying their vector keys using the DeleteVectors API. This operation is useful for removing outdated or incorrect data while preserving the rest of your vector data.

Using the AWS CLI

To delete vectors, use the following example commands. Replace the *user input placeholders* with your own information.

```
aws s3vectors delete-vectors \
 --vector-bucket-name "amzn-s3-demo-vector-bucket" \
 --index-name "idx" \
 --keys '["vec2","vec3"]'
```

Using the AWS SDKs

SDK for Python (Boto3)

```
import boto3

# Create a S3 Vectors client in the AWS Region of your choice.
s3vectors = boto3.client("s3vectors", region_name="us-west-2")

#Delete vectors in a vector index
response = s3vectors.delete_vectors(
    vectorBucketName="media-embeddings",
    indexName="movies",
    keys=["Star Wars", "Finding Nemo"])
```

Metadata filtering

Metadata filtering allows you to filter query results based on specific attributes attached to your vectors. You can use metadata filters with query operations to find vectors that match both similarity criteria and specific metadata conditions.

S3 Vectors supports two types of metadata: filterable metadata and non-filterable metadata. The key difference is that filterable metadata can be used in query filters but has stricter size

limitations, while non-filterable metadata can't be used in filters but can store larger amounts of data within its size limits. For more information about metadata limits, including size limits per vector and maximum metadata keys per vector, see Limitations and restrictions.

S3 Vectors evaluates your metadata filter before it runs vector search, a technique known as pre-filtering. S3 Vectors first identifies the vectors that match your filter, then only searches those vectors for the most similar ones, ensuring high recall even when filters match a small fraction of vectors. For example, if you search for similar movie embeddings and you filter by genre='mystery', S3 Vectors first identifies the vectors where the genre metadata is 'mystery', then only searches those for the closest matches to your query vector.

Pre-filtering applies to vector indexes whose index mode is `ENHANCED`. Vector buckets created on or after September 30, 2026 create `ENHANCED` indexes. In a vector bucket created before that date, indexes have the index mode `CLASSIC`.

S3 Vectors performs vector search and filter evaluation in tandem on a vector index whose index mode is `CLASSIC`. S3 Vectors searches through candidate vectors in the index to find the top K similar vectors while simultaneously validating if each candidate vector matches your metadata filter conditions. On a `CLASSIC` index, queries with filters may return fewer than top K results when the vector index contains very few matching results.

To move an existing index to `ENHANCED`, see Changing a vector index's mode.

Topics

- Filterable metadata
- Filter constraints per query
- Examples of valid filterable metadata
- Non-filterable metadata
- Query performance with filters

Filterable metadata

Filterable metadata allows you to filter query results based on specific metadata values. By default, all metadata fields are filterable in a similarity query unless explicitly specified as non-filterable during vector index creation. S3 Vectors supports string, number, boolean, and list types of metadata with a size limit per vector. The metadata type is ideal for attributes that you want to filter on, such as categories, timestamps, or status values.

If the metadata size exceeds the supported limits, the PutVectors API operation will return a `400 Bad Request` error. For more information about the filterable metadata size limit per vector, see Limitations and restrictions.

The following operations can be used with filterable metadata.

Operator	Valid Input Types	Description
`$eq`	String, Number, Boolean	Exact match comparison for single values. When comparing with an array metadata value, returns true if the input value matches any element in the array. For example, `{"category": {"$eq": "documentary"}}` would match a vector with metadata `"category": ["documentary", "romance"]` .
`$ne`	String, Number, Boolean	Not equal comparison
`$gt`	Number	Greater than comparison
`$gte`	Number	Greater than or equal comparison
`$lt`	Number	Less than comparison
`$lte`	Number	Less than or equal comparison
`$startsWith`	String	Prefix match. Matches values that begin with the specified string.
`$in`	Non-empty array of primitives	Match any value in array

Operator	Valid Input Types	Description
`$nin`	Non-empty array of primitives	Match none of the values in array
`$exists`	Boolean	Check if field exists
`$and`	Non-empty array of filters	Logical AND of multiple conditions
`$or`	Non-empty array of filters	Logical OR of multiple conditions

`$startsWith` requires `ENHANCED` query behavior. It is available on a vector index whose index mode is `ENHANCED`, and on a `CLASSIC` index when the request sets `queryMode` to `ENHANCED`.

Filter constraints per query

On a vector index whose index mode is `ENHANCED`, a single query filter can use up to 100 filter constraints. Each value the filter evaluates counts as one constraint: `{"category": "electronics"}` is one, `{"region": {"$in": ["us-east-1", "us-west-2", "eu-west-1"]}}` is three, and `{"$and": [{"category": "electronics"}, {"price": {"$lte": 500}}]}` is two. This limit only applies to `ENHANCED` indexes.

Typical filtered queries are well within 100 constraints. For guidance on writing filters that stay within the limit, see S3 Vectors best practices.

Examples of valid filterable metadata

Simple equality

```
{"genre": "documentary"}
```

This filter matches vectors where the genre metadata key equals "documentary". When you don't specify an operator, S3 Vectors automatically uses the $eq operator.

Explicit equality

```
// Example: Exact match
```

```
{"genre": {"$eq": "documentary"}}
```

```
// Example: Not equal to
{"genre": {"$ne": "drama"}}
```

Numeric comparison

```
{"year": {"$gt": 2019}}
```

```
{"year": {"$gte": 2020}}
```

```
{"year": {"$lt": 2020}}
```

```
{"year": {"$lte": 2020}}
```

Prefix match

```
{"s3_path": {"$startsWith": "/marketing/"}}
```

This filter matches vectors whose s3_path metadata begins with "/marketing/". Useful for hierarchical paths and URL prefixes.

Array operations

```
{"genre": {"$in": ["comedy", "documentary"]}}
```

```
{"genre": {"$nin": ["comedy", "documentary"]}}
```

Existence check

```
{"genre": {"$exists": true}}
```

The `$exists` filter matches vectors that have a "genre" metadata key, regardless of the value that's stored for that metadata key.

Logical operations

```
{"$and": [{"genre": {"$eq": "drama"}}, {"year": {"$gte": 2020}}]}
```

```
{"$or": [{"genre": {"$eq": "drama"}}, {"year": {"$gte": 2020}}]}
```

Price range (Multiple conditions on the same field)

```
{"price": {"$gte": 10, "$lte": 50}}
```

For more information about how to query vectors with metadata filtering, see Metadata filtering.

Non-filterable metadata

Non-filterable metadata can't be used in query filters but can store larger amounts of contextual data than filterable metadata. It's ideal for storing large text chunks, detailed descriptions, or other contextual information that doesn't need to be searchable but can be returned with query results. For example, you might store full document text, image descriptions, or detailed product specifications as non-filterable metadata.

Non-filterable metadata keys must be explicitly configured during vector index creation. Once a metadata key is designated as non-filterable during index creation, it can't be changed to filterable later. You can configure multiple metadata keys as non-filterable per vector index, with each metadata key name limited to 63 characters. For more information about the maximum number of non-filterable metadata keys that's allowed per vector index, see Limitations and restrictions.

While you can't filter on non-filterable metadata, you can retrieve it alongside query results using the `return-metadata` parameter. You can use non-filterable metadata for some use cases as follows.

- Use it to provide context for your application without parsing separate data sources.
- Store larger text chunks that would exceed the filterable metadata size limits.
- Include it in vector exports by using the ListVectors API operation.

For more information about configuring non-filterable metadata, see Creating a vector index in a vector bucket.

Query performance with filters

Because an ENHANCED index evaluates your filter before it searches, the work a filtered query does depends on the filter you send. Three things increase that work, and with it the query's latency: a

larger vector index, a filter that matches a larger share of the vectors in the index, and a filter with more constraints.

Because actual performance varies with your dataset size, dimensions, and filters, we recommend testing with representative data and queries. For guidance on writing filters, see S3 Vectors best practices.

Limitations and restrictions

Amazon S3 Vectors has certain limitations and restrictions that you should be aware of when planning your vector storage and search applications.

- Vector buckets per AWS Region in an account: 10,000
- Vector indexes per vector bucket: 10,000
- Vectors per vector index: Up to 2 billion
- Dimension value per vector: 1 to 4,096
- Total metadata per vector: Up to 40 KB (filterable + non-filterable)
- Total metadata keys per vector: Up to 50
- Filterable metadata per vector: Up to 2 KB
- Non-filterable metadata keys per vector index: Up to 10
- Combined PutVectors and DeleteVectors requests per second per vector index: Up to 1,000
- Combined vectors inserted and deleted per second per vector index: Up to 2,500
- Request payload size: Up to 20 MiB
- Vectors per PutVectors API call: Up to 500
- Vectors per DeleteVectors API call: Up to 500
- Vectors per GetVectors API call: Up to 100
- Top-K results per QueryVectors request: Up to 10,000
- Filter constraints per QueryVectors request on an `ENHANCED` index: Up to 100
- Results per page in a QueryVectors response: Up to 100
- Vectors listed per page in a ListVectors response: Up to 1,000
- Vector buckets listed per page in a ListVectorBuckets response: Up to 500.
- Vector indexes listed per page in a ListIndexes response: Up to 500.
- Segment count for parallel listing in a ListVectors API call: Up to 16

S3 Vectors best practices

Amazon S3 Vectors delivers purpose-built, cost-optimized vector storage for use by AI-enabled applications and semantic search of your content stored in Amazon S3. Designed to provide S3 level elasticity and durability for storing vector datasets with sub-second query performance for cold queries and as low as 100 milliseconds for warm queries, S3 Vectors is ideal for applications that need to build and grow vector indexes. With S3 Vectors you can use a dedicated set of API operations to store, access, and perform similarity queries on vector data without provisioning any infrastructure. For more information, see Working with S3 Vectors and vector buckets.

To ensure the maximum benefit from S3 Vectors, we recommend that you perform the following best practices.

Inserting and deleting vectors

Your application can achieve up to one thousand PutVectors or DeleteVectors requests per second per vector index, or can insert or delete up to two thousand five hundred vectors per second per vector index — whichever limit is reached first. If you exceed the request rates, you might receive a `429 TooManyRequestsException` error.

To optimize costs, we recommend inserting and deleting vectors in large batches, up to the maximum batch size of 500 vectors per API request. If your workload requires smaller batches, you can send concurrent requests up to the 1,000 requests per second limit. To reach maximum throughput of 2,500 vectors per second, you can send 5 batches per second with 500 vectors each, or 1,000 batches per second with an average of 2.5 vectors each.

Accessing and querying vectors in an S3 vector index

Your application can achieve hundreds of QueryVectors, GetVectors, or ListVectors requests per second per S3 vector index. If you exceed the request rates, you might receive a `429 TooManyRequestsException` error. We recommend you use a retry mechanism and configure your application to send fewer requests.

Scaling across vector indexes

To improve query performance per vector index, consider configuring your application to divide vectors across multiple vector indexes when possible. For example, if you have multi-tenant workloads and your application queries each tenant independently, consider storing each tenant's vectors in a separate vector index. For more information, see Vector indexes.

Implementing multi-tenancy with separate vector indexes

You can achieve multi-tenancy by organizing your vector data using a single vector index for each tenant. You can use IAM and bucket policies to restrict each tenant's access to only their designated vector index. This approach helps maintain data isolation and simplifies management by removing the need to create separate buckets for each tenant. For more information, see Identity and Access management in S3 Vectors.

Configuring non-filterable metadata fields for vector indexes

When creating a vector index, configure metadata fields that don't require filtering as non-filterable metadata keys. For example, store text chunks for vector embeddings as non-filterable metadata fields when you need them only for reference. For more information, see Non-filterable metadata.

Choosing an index mode

Use the `ENHANCED` index mode for workloads that filter on metadata. It applies your filter before the vector search, ensuring high recall even when filters match a small fraction of vectors, and it supports the `$startsWith` operator. Use `CLASSIC` only if your queries can neither be simplified to 100 or fewer filter constraints nor split across smaller queries; for both techniques, see Writing filters for lower latency. To run a single query with `ENHANCED` behavior without changing an index, set `queryMode` to `ENHANCED` on a `QueryVectors` request.

Writing filters for lower latency

A filtered query's latency grows with the work its filter does: with the size of the vector index, with the share of the index your filter matches, and with the number of constraints the filter evaluates. To keep filtered queries fast, prefer selective filters and use the fewest constraints that express what you need.

When a query would otherwise filter on a long list of values, attach a single metadata key that captures the group those values belong to, and filter on that one key instead. Filtering on a list uses one constraint per value; the following uses 3 constraints:

```
{"documentId": {"$in": ["doc-001", "doc-002", "doc-003"]}}
```

A user who can access 300 documents would need a 300-value list, which uses 300 constraints. Instead, attach a `caseId` to each vector when you write it, and filter on that single key, which uses one constraint:

```
{"caseId": "case-4471"}
```

If a query cannot be simplified this way, you can split its filter across smaller queries, run them in parallel, and merge the results by distance. Set `returnDistance` to `true` on each query so that every result includes its distance to merge on. For queries that must match a large share of your index, you can also divide the vectors across multiple vector indexes so that each query filters less data.

Creating vector embeddings and performing semantic searches with `s3vectors-embed-cli`

Amazon S3 Vectors provides a standalone open-source tool called Amazon S3 Vectors Embed CLI (`s3vectors-embed-cli`) that simplifies working with vector data by combining embedding generation with vector operations in single commands. This CLI tool helps you get started with S3 Vectors quickly by automating vector embedding generation with Amazon Bedrock foundation models and semantic search operations within your vector indexes.

The S3 Vectors Embed CLI provides two main commands for integrating Amazon Bedrock embedding models with S3 Vectors operations:

- `s3vectors-embed put`: Generate and insert vector embeddings into an vector index. Specifically, convert text and images into vector embeddings through Amazon Bedrock models and automatically store them in your vector index.
- `s3vectors-embed query`: Generate vector embeddings from your query input through Amazon Bedrock models and query vectors in your vector index.

The Amazon S3 Vectors Embed CLI is available in the Amazon Web Services - Labs GitHub repository. For detailed installation instructions, command parameters, examples, and best practices, see the Amazon S3 Vectors Embed CLI GitHub repository.

For the lower-level S3 Vectors API operations that provide more control and customization, see Amazon S3 Vectors in the *Amazon Simple Storage Service API Reference*.

Using S3 Vectors with other AWS services

S3 Vectors integrates with other AWS services to enhance your vector processing capabilities and provide comprehensive solutions for AI and machine learning workloads. These integrations allow you to leverage the cost-effective storage of S3 Vectors alongside the specialized capabilities of other AWS services.

Available integrations

S3 Vectors provides native integrations with the following AWS services:

- Amazon OpenSearch Service - You can export a snapshot of a vector index to Amazon OpenSearch Service for high queries per second (QPS) and low latency vector search. Additionally, Amazon OpenSearch Service adds Amazon S3 Vectors as a new low-cost engine for customers who want to optimize cost while continuing to use Amazon OpenSearch Service API operations for advanced search functionality including hybrid search, aggregations, advanced filtering, faceted search, and more.
- Amazon Bedrock Knowledge Bases - Use S3 Vectors as your vector store for Retrieval Augmented Generation (RAG) applications, reducing storage costs while maintaining query performance for knowledge base operations. You can access this integration through the Amazon Bedrock console or Amazon SageMaker AI Unified Studio.

Integration benefits

These integrations provide several key advantages:

- **Cost optimization**: Store large vector datasets cost-effectively in S3 Vectors while using specialized services for specific workloads, such as using Amazon OpenSearch for advanced search functionality.
- **Performance flexibility**: Choose the right integration for your performance requirements: S3 Vectors for lower throughput storage and sporadic querying, and other services for high-throughput, low-latency operations.
- **Workflow integration**: Seamlessly incorporate vector operations into existing AWS based AI and ML pipelines.
- **Simplified management**: Reduce operational complexity by using managed integrations rather than building custom solutions.

Topics

- Using S3 Vectors with OpenSearch Service
- Using S3 Vectors with Amazon Bedrock Knowledge Bases

Using S3 Vectors with OpenSearch Service

Amazon S3 Vectors integrates with OpenSearch to provide flexible vector storage and search capabilities. This integration allows you to optimize costs by storing vectors in S3 Vectors while leveraging the advanced search features of OpenSearch.

There are two integrations between S3 Vectors and OpenSearch. One is to export vector data from S3 Vectors to OpenSearch Serverless for high-performance search capabilities. The other uses S3 Vectors as a cost-effective storage engine within OpenSearch while maintaining access to OpenSearch functionality.

Export to OpenSearch Serverless

You can export vector indexes from S3 Vectors to OpenSearch Serverless collections for high-performance search operations, hybrid search, aggregations, advanced filtering, and faceted search. When you export, the data is copied to OpenSearch Serverless while remaining in S3 Vectors, which means you'll be paying for both services during this time.

When to use this integration

Consider exporting to OpenSearch Serverless from S3 Vectors when you need the following:

- **Hybrid search capabilities** that combine vector similarity with keyword search.
- **High query throughput** for demanding workloads.
- **Low-latency responses** for real-time applications that require millisecond response times.
- **Advanced analytics** that include aggregations, faceted search, and complex filtering.

Prerequisites

Before using S3 Vectors with OpenSearch, ensure you have the following:

- An existing S3 vector bucket with vector indexes containing your data.
- Appropriate IAM permissions for both S3 Vectors and OpenSearch Service.

- An understanding of your performance requirements to choose the appropriate integration method.

Getting started

Using the AWS Management Console

To export vector data to OpenSearch

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket containing the vector data that you want to export.
4. For **Vector indexes**, choose the radio button next to the vector index that you want to export.
5. Choose **Advanced search export**, then choose **Export to OpenSearch**.

> **Important**
>
> - **Point-in-time export**: The export captures data up to the initiation of the export. If you make updates to your vector data during the ingestion to OpenSearch, not all updates will be reflected in OpenSearch.
> - **One-time operation**: This is a one-time export and will not stay in sync with your S3 Vectors data. You must manually re-export to capture any subsequent changes.

Then, to configure and manage the integration of S3 Vectors with Amazon OpenSearch Service, you'll work primarily through the OpenSearch console.

To view exports to OpenSearch

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket containing the vector data that you want to export.

4. For **Vector indexes**, choose **Advanced search export**, then choose **View exports to OpenSearch**.

Then, you'll view exports to OpenSearch through the OpenSearch console.

For more information about creating and managing OpenSearch Serverless collections, see Creating and managing Amazon OpenSearch Service Serverless collections in the *Amazon OpenSearch Service Developer Guide*.

OpenSearch with S3 Vectors engine

You can use S3 Vectors as the underlying storage engine for Amazon OpenSearch Managed clusters, providing cost-optimized vector storage while maintaining OpenSearch functionality.

When to use this integration

Consider using OpenSearch with the S3 Vectors engine when you need the following:

- **Hybrid search capabilities** that combine vector similarity with keyword search.
- **Lower query throughput** that may have less frequent or sporadic usage patterns.
- **Higher latency tolerance** for applications that can accept longer response times in exchange for cost savings.
- **Advanced analytics** that include aggregations, faceted search, and complex filtering.
- **Existing OpenSearch workflows** that you want to extend with cost-effective vector storage.

Prerequisites

Before using OpenSearch with S3 Vectors engine, ensure you have:

- An existing OpenSearch managed domain. For more information, see Creating and managing Amazon OpenSearch Service domains in the *Amazon OpenSearch Service Developer Guide*.
- An understanding of your performance requirements to choose the appropriate integration method.

Getting Started

To use OpenSearch with S3 Vectors engine, set your engine to `S3_Vectors` during index creation in OpenSearch. For more information about the template that you use when creating an index

in OpenSearch Service, including where to specify the engine type, see Methods and engines. For more information about the integration between OpenSearch and S3 Vectors engine, see Advanced search capabilities with an S3 Vectors engine in the *Amazon OpenSearch Service Developer Guide*.

Using S3 Vectors with Amazon Bedrock Knowledge Bases

S3 Vectors integrates with Amazon Bedrock Knowledge Bases and Amazon SageMaker AI Unified Studio to simplify and reduce the cost of vector storage for retrieval augmented generation (RAG) applications.

For more information about high-level CLI commands that integrate Amazon Bedrock embedding models with S3 Vectors operations, see Creating vector embeddings and performing semantic searches with `s3vectors-embed-cli`.

Topics

- Integration overview
- When to use this integration
- Supported embedding models
- Prerequisites and permissions
- Creating a knowledge base with S3 Vectors
- Managing and querying your knowledge base
- Limitations

Integration overview

When creating a knowledge base in Amazon Bedrock, you can select S3 Vectors as your vector store. This integration provides the following:

- **Cost savings** for RAG applications with large vector datasets.
- **Seamless integration** with the fully managed RAG workflow of Amazon Bedrock.
- **Automatic vector management** handled by the Amazon Bedrock service.
- **Sub-second cold query latency and as low as 100 millisecond warm query latency** for knowledge base retrieval operations.

Amazon Bedrock Knowledge Bases provides a fully managed end-to-end RAG workflow. When you create a knowledge base with S3 Vectors, Amazon Bedrock automatically fetches data from your S3 data source, converts content into text blocks, generates embeddings, and stores them in your vector index. You can then query the knowledge base and generate responses based on chunks retrieved from your source data.

When to use this integration

Consider using S3 Vectors with Amazon Bedrock Knowledge Bases when you need the following:

- **Cost-effective vector storage** for large datasets where sub-second query latency meets your application requirements.
- **Text and image-based document retrieval** for use cases like searching through manuals, policies, and visual content.
- **RAG applications** that prioritize storage cost optimization over ultra-low latency responses.
- **Managed vector operations** without needing to learn S3 Vectors API operations directly - you can continue using familiar Amazon Bedrock interfaces.
- **Long-term vector storage** with the durability and scalability of Amazon S3

This integration is ideal for organizations building RAG applications that need to search through and extract insights from written content and images, where the cost benefits of S3 Vectors align with acceptable query performance requirements.

Supported embedding models

Refer to supported models for vector embeddings in the *Amazon Bedrock User Guide*.

Prerequisites and permissions

Before creating a knowledge base with S3 Vectors, ensure you have the following:

- Appropriate IAM permissions for both S3 Vectors and Amazon Bedrock services. For more information about IAM permissions for S3 Vectors, see the section called “Identity and Access management in S3 Vectors”. For more information about IAM permissions for your Amazon Bedrock Knowledge Bases service role to access S3 Vectors, see Permissions to access your vector store in Amazon S3 Vectors in the *Amazon Bedrock User Guide*.
- Your source documents prepared for ingestion into the knowledge base.
- An understanding of your embedding model requirements.

When setting up security configurations, you can choose an IAM role that provides Amazon Bedrock permission to access required AWS services. You can let Amazon Bedrock create the service role or use your own custom role. If you use a custom role, configure a vector bucket policy that restricts access to the vector bucket and vector index to the custom role.

For detailed information about required permissions and IAM roles, see Create a service role for Amazon Bedrock Knowledge Bases in the *Amazon Bedrock User Guide*. The service role must also have permissions for S3 Vectors and AWS KMS API operations.

Creating a knowledge base with S3 Vectors

You can create a knowledge base that uses S3 Vectors through two methods.

Method one: Using the Amazon Bedrock console

When creating a knowledge base in the Amazon Bedrock console, you can choose "S3 vector bucket" as your vector store option. You have two setup options:

- **Quick create a new vector store** - Amazon Bedrock creates an S3 vector bucket and vector index and configures them with the required settings for you. By default, the vector bucket is encrypted using server-side encryption with Amazon S3 managed keys (SSE-S3). You can optionally encrypt the bucket using AWS KMS. For more information about **Quick create a new vector store** in the console, see Create a knowledge base by connecting to a data source in Amazon Bedrock Knowledge Bases in the *Amazon Bedrock User Guide*.
- **Choose a vector store you have created** - Choose an existing S3 vector bucket and vector index from your account that you've previously created. For more information about creating an S3 vector bucket and vector index in the Amazon Bedrock Knowledge Bases console, see the S3 Vectors tab in Prerequisites for using a vector store you created for a knowledge base in the *Amazon Bedrock User Guide*.

For detailed step-by-step instructions, see Create a knowledge base by connecting to a data source in Amazon Bedrock Knowledge Bases in the *Amazon Bedrock User Guide*.

Method two: Using Amazon SageMaker Unified Studio

You can also create and manage knowledge bases with S3 Vectors through Amazon Bedrock in Amazon SageMaker AI Unified Studio. This provides a unified development environment for building and testing AI applications that use knowledge bases.

Amazon Bedrock in SageMaker AI Unified Studio is designed for users who need integrated notebook capabilities and work across multiple AWS ML and analytics services. You can quickly create an S3 vector bucket and configure it as the vector store for your knowledge bases when you build generative AI applications.

For information about using S3 Vectors with Amazon Bedrock in SageMaker AI Unified Studio, see Add a data source to your Amazon Bedrock app in the *SageMaker AI Unified Studio User Guide*.

Managing and querying your knowledge base

Data synchronization and management

Amazon Bedrock Knowledge Bases offers ingestion job operations to keep your data source and vector embeddings synchronized. When you sync your data source, Amazon Bedrock scans each document and verifies whether it has been indexed into the vector store. You can also directly index documents into the vector store using the IngestKnowledgeBaseDocuments operation. Best practice is to create a separate vector store for each knowledge base to ensure data synchronization.

When you delete a knowledge base or data source resource, Amazon Bedrock offers two data deletion policies: `Delete` (default) and `Retain`. If you choose the `Delete` policy, vectors in the vector index and vector bucket are automatically deleted.

Querying and retrieval

After your knowledge base is set up, you can do the following:

- **Retrieve chunks** from your source data using the Retrieve API operation.
- **Generate responses** based on retrieved chunks using the RetrieveAndGenerate API operation.
- **Test queries** directly in the Amazon Bedrock console.

Responses are returned with citations to the original source data.

Limitations

When using S3 Vectors with Amazon Bedrock Knowledge Bases, you should know the following limitations:

- **Semantic search only**: S3 Vectors supports semantic search but not hybrid search capabilities.

- **S3 Vectors size limits**: Each vector has a total metadata size limit and a size limit for filterable metadata, which may limit custom metadata and filtering options. When using S3 Vectors as your vector store with Amazon Bedrock Knowledge Bases, you can attach up to 1KB of custom metadata and 35 metadata keys per vector.
- **Chunking strategy constraints**: When using very high token counts with hierarchical chunking in Amazon Bedrock Knowledge Bases, you can exceed the maximum metadata size limits as parent-child chunk relationships and hierarchical context are stored as non-filterable metadata in S3 Vectors. For more information about metadata size limits per vector, see Limitations and restrictions.
- **Floating-point vectors only**: Binary vector embeddings aren't supported.

For comprehensive guidance on working with Amazon Bedrock Knowledge Bases, see Retrieve data and generate AI responses with Amazon Bedrock Knowledge Bases in the *Amazon Bedrock User Guide*.

AWS Regions, endpoints, and quotas for S3 Vectors

The following sections include the supported AWS Regions and service quotas for Amazon S3 Vectors.

S3 Vectors AWS Regions and endpoints

Amazon S3 Vectors is currently available in the following AWS Regions. To connect programmatically to an AWS service, you use an endpoint. For more information about AWS service endpoints, see AWS service endpoints in the AWS General Reference. For more Amazon S3 endpoint information, see Amazon S3 endpoints and quotas in the AWS General Reference.

S3 Vectors endpoints are dual-stack endpoints that support requests over IPv6 and IPv4.

S3 Vectors supports private connectivity with AWS PrivateLink interface endpoints. For more information, see VPC endpoints for S3 Vectors.

S3 Vectors AWS Regions and endpoints

Regio Name	Region	Endpoint	Protocol	Signature Version(s) Support
Africa (Cape Town)	af-south-1	s3vectors.af-south-1.api.aws	HTTPS	4
Asia Pacific (Hong Kong)	ap-east-1	s3vectors.ap-east-1.api.aws	HTTPS	4
Asia Pacific (Hyder d)	ap-south-2	s3vectors.ap-south-2.api.aws	HTTPS	4
Asia Pacific (Jakar	ap-southeast-3	s3vectors.ap-southeast-3.api.aws	HTTPS	4

S3 Vectors service quotas

Quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. The limits are the service quotas for S3 Vectors resources.

For detailed limits that apply to S3 Vectors, see Limitations and restrictions.

Unless otherwise noted, each quota is per AWS Region. You can request increases for some quotas, and other quotas can't be increased. For more information about requesting a quota increase, see Requesting a quota increase in the *Service Quotas User Guide*. For more Amazon S3 quota information, see Amazon S3 endpoints and quotas in the *AWS General Reference*.

Security in S3 Vectors

Amazon S3 Vectors offers highly durable vector storage. Data written to S3 Vectors is stored on S3, which is designed for 99.999999999% (11 nines) of data durability.

S3 Vectors implements a security approach that includes encryption at rest and secure data transmission. Whether you're storing millions of vectors for machine learning applications or building semantic search systems, S3 Vectors provides the security controls necessary to meet your organization's compliance and data protection requirements.

Topics

- Identity and Access management in S3 Vectors
- Data protection and encryption in S3 Vectors
- VPC endpoints for S3 Vectors

Identity and Access management in S3 Vectors

Access management in S3 Vectors follows AWS security best practices, providing multiple layers of control to ensure that only authorized users and applications can access your vector data. The service integrates with IAM and supports both identity-based and resource-based policies, giving you flexibility in how you structure and manage permissions across your organization.

Authenticating and authorizing requests

S3 Vectors uses AWS standard authentication and authorization mechanisms to secure access to vector buckets and their contents. Every request to S3 Vectors must be authenticated using valid AWS credentials, and the service evaluates permissions based on the combination of identity-based policies, resource-based policies, and any applicable service control policies.

The authentication process begins when a client makes a request to S3 Vectors using AWS credentials (access keys, temporary credentials from AWS STS, or IAM roles). The service validates these credentials and then evaluates the permissions associated with the authenticated identity against the requested action and target resource. This evaluation process considers multiple policy types and applies the principle of least privilege to determine whether the request should be allowed or denied.

Authorization in S3 Vectors operates at multiple levels of granularity. You can control access at the vector bucket level, individual vector index level, or even specific operations within an index. This hierarchical permission model allows you to implement sophisticated access control schemes that align with your organizational structure and data governance requirements.

Resource types defined for vector buckets

S3 Vectors defines specific resource types that can be referenced in IAM policies and resource-based policies. Understanding these resource types is essential for creating effective access control policies that provide the right level of access to the right users and applications.

The following table describes the resource types available in S3 Vectors.

Resource types available in S3 Vectors

Resource type	ARN format	Description
VectorBucket	arn:aws:s3vectors:*region*:*123456789012* :bucket/*bucket-name*	Represents a vector bucket and is used for bucket-level operations such as creating,

Resource type	ARN format	Description
		deleting, or configuring the bucket
Index	arn:aws:s3vectors:*region*:*123456789012* :bucket/*bucket-name* /index/*index-name*	Represents a vector index within a bucket and is used for index-specific operations such as querying vectors or managing index contents

Policy actions for vector buckets

S3 Vectors provides a comprehensive set of policy actions that correspond to the various operations you can perform on vector buckets and indexes. These actions are designed to provide fine-grained control over who can perform specific operations, allowing you to implement the principle of least privilege effectively.

The following table lists all available policy actions for S3 Vectors resources.

Policy actions for S3 Vectors resources

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Account	ListVectorBuckets	s3vectors:ListVectorBuckets	Grants permission to list all vector buckets in the account and region	List	
VectorBucket	CreateVectorBucket	s3vectors:CreateVectorBucket	Grants permission to create a new vector bucket with	Write	s3vectors:sseType, s3vectors:kmsKeyArn

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
			specified configuration		
VectorBucket	GetVectorBucket	s3vectors:GetVectorBucket	Grants permission to retrieve vector bucket attributes and configuration	Read	
VectorBucket	PutVectorBucketDefaultIndexMode	s3vectors:PutVectorBucketDefaultIndexMode	Grants permission to set the default index mode for vector indexes created in a vector bucket	Write	
VectorBucket	DeleteVectorBucket	s3vectors:DeleteVectorBucket	Grants permission to delete an empty vector bucket	Write	
VectorBucket	ListIndexes	s3vectors:ListIndexes	Grants permission to list all indexes within a vector bucket	List	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
VectorBucket	PutVectorBucketPolicy	s3vectors:PutVectorBucketPolicy	Grants permission to apply or update a resource-based policy on a vector bucket	Permissions management	
VectorBucket	GetVectorBucketPolicy	s3vectors:GetVectorBucketPolicy	Grants permission to retrieve the resource-based policy attached to a vector bucket	Read	
VectorBucket	DeleteVectorBucketPolicy	s3vectors:DeleteVectorBucketPolicy	Grants permission to remove the resource-based policy from a vector bucket	Permissions management	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	CreateIndex	s3vectors:CreateIndex	Grants permission to create a new vector index with specified dimensions and metadata configuration	Write	
Index	GetIndex	s3vectors:GetIndex	Grants permission to retrieve vector index attributes and configuration	Read	
Index	UpdateIndexMode	s3vectors:UpdateIndexMode	Grants permission to change the index mode of a vector index	Write	
Index	DeleteIndex	s3vectors:DeleteIndex	Grants permission to delete a vector index and all its contents	Write	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	QueryVectors	(Required) s3vectors:QueryVectors	Grants permission to perform similarity queries against vectors in an index. **With `s3vectors:QueryVectors` only**, you can retrieve vector keys of approximate nearest neighbors and their computed distances from the query vector. This permission is sufficient only when you don't set any metadata filters and don't request	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
			metadata (by keeping the `returnMetadata` parameter set to false or not specified).		

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
		(Conditionally required): s3vectors:GetVectors	Required if you set metadata filters, set `returnMetadata` to true in your request. **With both `s3vectors:QueryVectors` and `s3vectors:GetVectors`**, you can filter results by using metadata criteria and retrieve vector keys along with their associated data, metadata, and computed distances from the query vector.	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	PutVectors	s3vectors:PutVectors	Grants permission to add or update vectors in an index	Write	
Index	GetVectors	s3vectors:GetVectors	Grants permission to retrieve specific vectors and their metadata by vector key	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	ListVectors	(Required) s3vectors:ListVectors	Grants permission to list vector keys in an index. **With `s3vectors:ListVectors` only**, you can list vector keys when both `returnData` and `returnMetadata` parameters are false or not specified.	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
		(Conditionally required): s3vectors:GetVectors	Required if you set either `returnData` or `returnMetadata` parameter to true in your request. **With both `s3vectors:ListVectors` and `s3vectors:GetVectors`**, you can retrieve vector keys along with their associated data and metadata by setting `returnData` and `returnMetadata` to true.	Read	

Resource type	API operations	Policy actions	Description of policy actions	Access level	Condition keys
Index	DeleteVectors	s3vectors:DeleteVectors	Grants permission to delete specific vectors from an index	Write	

These actions can be combined in various ways to create policies that match your specific access requirements. For example, you might create a read-only policy that includes `s3vectors:GetVectorBucket`, `s3vectors:ListIndexes`, `s3vectors:QueryVectors`, and `s3vectors:GetVectors` actions, or a policy that includes query and vector retrieval permissions but excludes administrative actions like creating or deleting indexes.

Condition keys for vector buckets

Condition keys for vector buckets

	Condition keys	Description	Type
1	s3vectors:sseType	Filters access by server-side encryption type **Valid values:** `AES256 | aws:kms`	String
2	s3vectors:kmsKeyArn	Filters access by the AWS AWS KMS key ARN for the key used to encrypt a vector bucket	ARN

S3 Vectors identity-based policy examples

IAM identity-based policies are JSON documents that you attach to IAM users, groups, or roles to define what actions they can perform on S3 Vectors resources. These policies are evaluated in the context of the identity making the request and provide a centralized way to manage permissions across your AWS environment. Identity-based policies provide a clear audit trail of who has what permissions and can be easily modified as your access requirements evolve.

When designing identity-based policies for S3 Vectors, consider the different types of users and applications that will interact with your vector data. Common patterns include data scientists who need to query vectors, data engineers who need to load and manage vector data, administrators who need full control over bucket configuration, and applications that need specific read or write access to particular vector indexes.

Example policies

Administrative access policy

This policy provides full administrative access to S3 Vectors resources, suitable for platform administrators or DevOps teams:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAdministrativeAccess",
            "Effect": "Allow",
            "Action": [
                "s3vectors:CreateVectorBucket",
                "s3vectors:PutVectorBucketPolicy",
                "s3vectors:DeleteVectorBucket",
                "s3vectors:DeleteVectorBucketPolicy",
                "s3vectors:GetVectorBucket",
                "s3vectors:GetVectorBucketPolicy",
                "s3vectors:ListVectorBuckets",
                "s3vectors:CreateIndex",
                "s3vectors:DeleteIndex",
                "s3vectors:GetIndex",
                "s3vectors:ListIndexes",
                "s3vectors:DeleteVectors",
                "s3vectors:GetVectors",
                "s3vectors:ListVectors",
```

```
                "s3vectors:PutVectors",
                "s3vectors:QueryVectors"
            ],
            "Resource": "*"
        }
    ]
}
```

Application-specific access policy

This policy is designed for applications that need to perform specific operations on designated vector indexes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowApplicationVectorAccess",
            "Effect": "Allow",
            "Action": [
                "s3vectors:QueryVectors",
                "s3vectors:GetVectors",
                "s3vectors:PutVectors",
                "s3vectors:ListVectors"
            ],
            "Resource": [
                "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-vector-bucket/index/product-recommendations",
                "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-vector-bucket/index/content-similarity"
            ]
        },
        {
            "Sid": "AllowGetIndex",
            "Effect": "Allow",
            "Action": "s3vectors:GetIndex",
            "Resource": "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-vector-bucket/index/*"
        },
        {
            "Sid": "AllowIndexInspection",
            "Effect": "Allow",
            "Action": "s3vectors:ListIndexes",
```

```
            "Resource": "arn:aws:s3vectors:aws-region:123456789012:bucket/amzn-s3-demo-
vector-bucket"
        }
    ]
}
```

S3 Vectors resource-based policy examples

Resource-based policies are attached to a resource. You can create resource-based policies for vector buckets. Resource-based policies for S3 Vectors use the standard AWS policy format in JSON that you attach directly to vector buckets to control access to the bucket and its contents.

Unlike identity-based policies that are attached to users, groups, or roles, resource-based policies are attached to the resource itself (the vector bucket) and can grant permissions to principals from other AWS accounts. This makes them ideal for scenarios where you need to share vector data across organizational boundaries or implement fine-grained access controls based on the specific resource being accessed.

Resource-based policies are evaluated in combination with identity-based policies, and the effective permissions are determined by the union of all applicable policies. This means that a principal needs permission from both the identity-based policy (attached to their user/role) and the resource-based policy (attached to the bucket) to perform an action, unless the resource-based policy explicitly grants the permission.

Example 1: Cross-account access policy

This policy demonstrates how to grant specific permissions to users from different AWS accounts:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CrossAccountBucketAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/Admin"
            },
            "Action": [
                "s3vectors:CreateIndex",
                "s3vectors:ListIndexes",
                "s3vectors:QueryVectors",
```

```
                "s3vectors:PutVectors",
                "s3vectors:DeleteIndex"
            ],
            "Resource": [
                "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket/*",
                "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket"
            ]
        }
    ]
}
```

Example 2: Deny vector index level actions

This policy demonstrates how to deny specific vector index level actions to an IAM role:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyIndexLevelActions",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/External-Role-Name"
            },
            "Action": [
                "s3vectors:QueryVectors",
                "s3vectors:PutVectors",
                "s3vectors:DeleteIndex",
                "s3vectors:GetVectors",
                "s3vectors:GetIndex",
                "s3vectors:DeleteVectors",
                "s3vectors:CreateIndex",
                "s3vectors:ListVectors"
            ],
            "Resource": "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket/*"
        }
    ]
}
```

Example 3: Deny modification operations at both vector index and bucket levels

This policy demonstrates how to deny modification requests for both vector index and bucket-level actions by specifying multiple resources:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyModificationActionsAtBucketandIndexLevels",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/External-Role-Name"
            },
            "Action": [
                "s3vectors:CreateVectorBucket",
                "s3vectors:DeleteVectorBucket",
                "s3vectors:PutVectorBucketPolicy",
                "s3vectors:DeleteVectorBucketPolicy",
                "s3vectors:CreateIndex",
                "s3vectors:DeleteIndex",
                "s3vectors:PutVectors",
                "s3vectors:DeleteVectors"
            ],
            "Resource": [
                "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket/*",
                "arn:aws:s3vectors:aws-region:111122223333:bucket/amzn-s3-demo-vector-bucket"
            ]
        }
    ]
}
```

Data protection and encryption in S3 Vectors

Amazon S3 Vectors provides 99.999999999% (11 9s) of durability for your vector data, which ensures exceptional reliability for your vector storage needs. This durability is backed by the proven infrastructure of Amazon S3, which is designed to maintain data integrity and availability even in the face of hardware failures or other disruptions.

Data protection in S3 Vectors encompasses multiple layers of security controls designed to protect your vector data both at rest and in transit.

By default, all new vectors in Amazon S3 Vectors vector buckets use server-side encryption with Amazon S3 managed keys (SSE-S3). When you create a vector bucket with SSE-S3 encryption, all subsequent operations on the bucket automatically use encryption.

S3 Vectors also integrates with AWS Key Management Service (KMS) to provide flexible encryption key management options, allowing you to choose customer-managed keys for permission control and auditability.

When creating a vector index within a vector bucket, you can optionally override the vector bucket level encryption settings and provide an encryption configuration (SSE-S3 or KMS) at the vector index level. If no specific encryption is specified upon vector index creation, the index will inherit the encryption configuration from the vector bucket it belongs to.

Setting server-side encryption behavior for Amazon S3 vector buckets and indexes

Encryption configuration in S3 Vectors is a fundamental security setting to specify when you create a vector bucket. This design ensures that all vector data stored in the bucket is encrypted from the moment of creation. By default, the encryption configuration applies to all vectors, vector indexes, and metadata within the bucket, providing consistent protection across your entire vector dataset in a vector bucket. You can also optionally override the vector bucket level encryption settings and provide a dedicated encryption configuration (SSE-S3 or AWS KMS) at the vector index level.

> **Important**
>
> Encryption settings for a vector bucket can't be changed after the vector bucket is created. You must carefully consider your encryption requirements during the bucket creation process, including compliance requirements, key management preferences, and integration with existing security infrastructure.

When you set the SSE-S3 or SSE-KMS encryption type at the vector bucket level, by default it applies to all vector indexes and vectors within the bucket. The encryption configuration applies to not only the vector data itself but also all associated metadata.

You can also optionally override the vector bucket level encryption settings and provide a dedicated encryption configuration (SSE-S3 or KMS) at the vector index level. Encryption settings for a vector index can't be changed after the vector index is created.

Using SSE-S3 encryption

Server-side encryption with Amazon S3 managed keys (SSE-S3) provides a simple and effective encryption solution for vector buckets where AWS manages all aspects of the encryption process. This encryption method uses AES-256 encryption and is designed to provide strong security with minimal operational overhead, providing organizations with robust encryption without the complexity of the needs to manage encryption keys.

With SSE-S3, Amazon S3 handles the generation, rotation, and management of encryption keys automatically. SSE-S3 provides strong security with no additional configuration or ongoing management requirements. The encryption and decryption processes are handled automatically by the service, and there are no additional charges for using SSE-S3 encryption beyond the standard S3 Vectors pricing.

Using SSE-KMS encryption

Server-side encryption with AWS Key Management Service keys (SSE-KMS) provides enhanced control over encryption keys and enables detailed audit logging of key usage. This encryption method is ideal for organizations with strict compliance requirements, those that need to implement custom key rotation policies, or environments where detailed audit trails of data access are required.

SSE-KMS allows you to use customer managed keys (CMKs) for encrypting your vector data. Customer managed keys provide the highest level of control, allowing you to define key policies, enable or disable keys, and monitor key usage through AWS CloudTrail. This level of control makes SSE-KMS particularly suitable for regulated industries or organizations with specific data governance requirements.

When using SSE-KMS with customer managed keys, you have complete control over who can use the keys to encrypt and decrypt data. You can create detailed key policies that specify which users, roles, or services can access the keys.

Important considerations for SSE-KMS

- **KMS key format requirements:** S3 Vectors requires that you specify KMS keys using the full Amazon Resource Name (ARN) format. Key IDs or key aliases aren't supported.

- **Service principal permissions:** When you use customer managed keys with S3 Vectors, you must explicitly grant permissions to the S3 Vectors service principal to use your KMS key. This requirement ensures that the service can encrypt and decrypt your data on your behalf. The service principal that requires access is `indexing.s3vectors.amazonaws.com`.

Example: KMS key policy for S3 Vectors

To use a customer managed KMS key with S3 Vectors, you must update your key policy to include permissions for the S3 Vectors service principal. Here's a comprehensive key policy example.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3VectorsServicePrincipal",
            "Effect": "Allow",
            "Principal": {
                "Service": "indexing.s3vectors.amazonaws.com"
            },
            "Action": "kms:Decrypt",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3vectors:aws-region:123456789012:bucket/
*"
                },
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                },
                "ForAnyValue:StringEquals": {
                    "kms:EncryptionContextKeys": ["aws:s3vectors:arn",
 "aws:s3vectors:resource-id"]
                }
            }
        },
        {
            "Sid": "AllowApplicationAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::123456789012:role/VectorApplicationRole",
```

```
                    "arn:aws:iam::123456789012:user/DataScientist"
                ]
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "s3vectors.aws-region.amazonaws.com"
                },
                "ForAnyValue:StringEquals": {
                    "kms:EncryptionContextKeys": ["aws:s3vectors:arn",
 "aws:s3vectors:resource-id"]
                }
            }
        }
    ]
}
```

- **Required KMS permissions:**
  - S3 Vectors service principal permission:
    - `kms:Decrypt` – Required by the S3 Vectors service principal (`indexing.s3vectors.amazonaws.com`) on your customer managed key to maintain and optimize the index in background operations
  - IAM principal permissions:
    - `kms:Decrypt` – Required for all vector-level operations (PutVectors, GetVectors, QueryVectors, DeleteVectors, ListVectors)
    - `kms:GenerateDataKey` – Required to create a vector bucket by using the customer managed key
- **Cross-account access considerations:** When implementing cross-account access patterns with SSE-KMS, you must ensure that the KMS key policy allows access from the appropriate principals in other accounts. The key ARN format becomes particularly important in cross-account scenarios, as it provides an unambiguous reference to the key regardless of the account context from which it's being accessed.

Setting encryption in S3 Vectors

This topic explains how to set the encryption configuration for your S3 vector buckets and indexes.

Before you begin, make sure you have the following:

- Appropriate permissions to view bucket and index properties.

Using the S3 console

To configure encryption for a vector bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. Choose **Create vector bucket**.
4. For **Bucket name**, enter a name for your bucket.

   The bucket name must:

   - Be unique within your account for this AWS Region
   - Be between 3 and 63 characters long
   - Consist only of lowercase letters, numbers, and hyphens (-)
5. For **Encryption**, choose

   - **Specify encryption type** – Choose a specific encryption method:
     - **Server-side encryption with Amazon S3 managed keys (SSE-S3)** – With SSE-S3, Amazon S3 handles the generation, rotation, and management of encryption keys automatically.
     - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** – Similar to SSE-S3, but uses customer managed keys (CMKs) in AWS KMS, giving you more control over your keys. For more information about customer managed keys, see Customer managed keys in the *AWS Key Management Service Developer Guide*.

       If you select this option, under **AWS KMS key**, choose one of the following options:

       - **Choose from your AWS KMS keys** – Select an existing KMS key from the dropdown list
       - **Enter AWS KMS key ARN** – Enter the Amazon Resource Name (ARN) of a KMS key

- **Create a KMS key** – Create a new customer managed key in the AWS KMS console. For more information, see Creating symmetric customer managed keys in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> The following requirements apply to the KMS key:
>
> - AWS KMS key ID must not be empty
> - Your KMS key must be in the same Region where this bucket is being created
> - AWS KMS key ARN must start with "arn:aws:kms:"

> **Important**
>
> Encryption settings can't be changed after the vector bucket is created.

6. If you chose **Enter AWS KMS key ARN**, enter the ARN in the text field provided.
7. If you chose **Create a KMS key**, the console opens the AWS KMS console in a new tab. For instructions on creating a KMS key, see Creating symmetric customer managed keys in the *AWS Key Management Service Developer Guide*.
8. Choose **Create vector bucket**.

> **Important**
>
> When using KMS encryption, ensure that the IAM principals that need to access objects in the bucket have the necessary KMS permission (kms:Decrypt) for the selected KMS key.

To configure encryption for a vector index

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Vector buckets**.
3. In the list of vector buckets, choose the name of the bucket where you want to create a vector index.

4. Choose **Create vector index**.
5. For **Vector index name**, enter a name for your vector index.

   Vector index names must be unique within the vector bucket. Index name must be between 3 and 63 characters. Valid characters are lowercase letters (a-z), numbers (0-9), hyphens (-), and dots (.). For more information about the vector index naming requirements, see Vector bucket naming rules.
6. For **Dimension**, enter the number of values in each vector.

   > **Note**
   >
   > - The value for **Dimension** determines how many numerical values each vector will contain.
   > - All vectors added to this index must have exactly this number of values.
   > - Dimension must be between 1 and 4096.
   > - A larger dimension requires more storage space.
   > - Choose based on your embedding model's output dimensions.
   >
   > For more information about the dimension requirements, see Limitations and restrictions.
7. For **Distance metric**, choose one of the following options:

   - **Cosine** – Measures the cosine of the angle between vectors. Best for normalized vectors and when direction matters more than magnitude
   - **Euclidean** – Measures the straight-line distance between vectors. Best when both direction and magnitude are important.
8. (Optional) Under **Non-filterable metadata**, configure metadata keys that will be stored but not used for filtering:

   To add non-filterable metadata keys:

   a. Choose **Add key**.

   b. Enter a key name (1-63 characters and unique within this vector index).

   c. Repeat to add additional keys (maximum 10 keys).

> **Note**
>
> You can attach filterable metadata as key-value pairs to each vector when you insert vector data after you create a vector index. By default, all metadata keys that are attached to vectors are filterable and can be used as filters in a similarity query. Only metadata keys that are specified as non-filterable during vector index creation are excluded from filtering. For more information about metadata size limits per vector, including both total and filterable metadata constraints, see Limitations and restrictions.

9. For **Encryption**, choose **Specify encryption type** and then choose one of the following options:

   - **Use bucket settings for encryption** – Amazon S3 applies the vector bucket encryption settings to encrypt vector data in the vector index.
   - **Override bucket settings for encryption** – Specify a specific encryption type for the vector index:
     - **Server-side encryption with Amazon S3 managed keys (SSE-S3)** – With SSE-S3, Amazon S3 handles the generation, rotation, and management of encryption keys automatically.
     - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** – Similar to SSE-S3, but uses customer managed keys (CMKs) in AWS KMS, giving you more control over your keys. For more information about customer managed keys, see Customer managed keys in the *AWS Key Management Service Developer Guide*.

       If you select this option, under **AWS KMS key**, choose one of the following options:

       - **Choose from your AWS KMS keys** – Select an existing KMS key from the dropdown list
       - **Enter AWS KMS key ARN** – Enter the Amazon Resource Name (ARN) of a KMS key
       - **Create a KMS key** – Create a new customer managed key in the AWS KMS console. For more information, see Creating symmetric customer managed keys in the *AWS Key Management Service Developer Guide*.

       > **Note**
       >
       > The following requirements apply to the KMS key:
       >
       > - AWS KMS key ID must not be empty.

- Your KMS key must be in the same Region where this bucket is being created.
- AWS KMS key ARN must start with "arn:aws:kms:"

Important

- Encryption settings can't be changed after the vector index is created.
- If you chose **Enter AWS KMS key ARN**, enter the ARN in the text field provided.
- If you chose **Create a KMS key**, the console opens the AWS KMS console in a new tab. For instructions on creating a KMS key, see *Creating symmetric customer managed keys* in the *AWS Key Management Service Developer Guide*.

Important

When using KMS encryption, ensure that the IAM principals that need to access objects in the bucket have the necessary KMS permission (kms:Decrypt) for the selected KMS key.

10. Under **Tags (Optional)**, you can add tags as key-value pairs to help track and organize vector index costs using AWS Billing and Cost Management. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**. You can enter up to 50 tags for a vector index. For more information, see Using tags with S3 vector buckets.
11. Review your configuration carefully.

Note

These settings can't be changed after creation.

12. Choose **Create vector index**.

Using the AWS CLI

The following example shows how to create a vector bucket with the SSE-S3 encryption configuration by using the AWS CLI. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3vectors create-vector-bucket \
        --vector-bucket-name "amzn-s3-demo-vector-bucket" \
        --encryption-configuration '{"sseType": "AES256"}'
```

The following examples shows how to create a vector bucket that uses the SSE-KMS encryption configuration with a customer managed key. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-vector-bucket \
        --vector-bucket-name "amzn-s3-demo-vector-bucket" \
        --encryption-configuration '{"sseType": "aws:kms", "kmsKeyArn":
 "arn:aws:kms:us-east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"}'
```

The following example shows how to create a vector index with the SSE-S3 encryption configuration by using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-index \
        --vector-bucket-name "amzn-s3-demo-vector-bucket" \
        --index-name "amzn-s3-demo-vector-index" \
        --encryption-configuration '{"sseType": "AES256"}'
```

The following examples shows how to create a vector index that uses the SSE-KMS encryption configuration with a customer managed key. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-index \
        --vector-bucket-name "amzn-s3-demo-vector-bucket" \
        --index-name "amzn-s3-demo-vector-index" \
        --encryption-configuration '{"sseType": "aws:kms",
 "kmsKeyArn": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890abc"}'
```

The following examples shows will create a vector index using the encryption settings of the vector bucket. To use this example, replace the *user input placeholders* with your own information.

```
aws s3vectors create-index \
        --vector-bucket-name "amzn-s3-demo-vector-bucket" \
        --index-name "amzn-s3-demo-vector-index" \
```

Viewing encryption configuration in S3 Vectors

After creating your vector bucket, you can verify the encryption configuration using the console. Alternatively, you can use the GetVectorBucket and GetIndex API operations through the AWS REST API, AWS CLI, or AWS SDKs.

Using the AWS CLI

Use the `get-vector-bucket` command to retrieve detailed bucket information, including encryption configuration. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3vectors get-vector-bucket \
  --vector-bucket-name amzn-s3-demo-vector-bucket
```

Use the `get-index` command to retrieve detailed vector index information, including encryption configuration. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3vectors get-index \
  --vector-bucket-name amzn-s3-demo-vector-bucket
  --index-name amzn-s3-demo-vector-index
```

VPC endpoints for S3 Vectors

To access S3 Vectors from your virtual private cloud (VPC), Amazon S3 supports interface VPC endpoints by using AWS PrivateLink (PrivateLink). PrivateLink provides private connectivity between your VPC and S3 Vectors without requiring an internet gateway or NAT device. Interface endpoints are represented by one ore more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests to S3 Vectors over interface endpoints stay on the AWS network.

You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your VPC with your on-premises network, see the *AWS Direct Connect User Guide* and the *AWS Site-to-Site VPN User Guide*. For general information about interface endpoints, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

Benefits of using PrivateLink with S3 Vectors

Using PrivateLink with S3 Vectors provides several security and operational benefits:

- **Enhanced security**: Traffic between your VPC and S3 Vectors remains within the AWS network and doesn't traverse the internet.
- **Simplified network architecture**: Access S3 Vectors without configuring internet gateways, NAT devices, or VPN connections.
- **Granular access control**: Use VPC endpoint policies to control which vector buckets and vector indexes can be accessed through the endpoint.
- **Compliance support**: Meet regulatory requirements that mandate private network connectivity for sensitive data.

VPC endpoint DNS names and resolution

When you create a VPC endpoint, S3 Vectors generates two types of endpoint-specific DNS names: Regional and Zonal.

The Regional and Zonal DNS names of interface VPC endpoints for S3 Vectors are as follows:

- **Regional DNS name**: `vpce-`*`1a2b3c4d-5e6f`*`.s3vectors.`*`region`*`.vpce.amazonaws.com` - The regional VPC endpoint DNS name. Always resolve to private IP addresses.
- **Zonal DNS name**: `vpce-`*`1a2b3c4d-5e6f`*`-`*`availability_zone_code`*`.s3vectors.`*`region`*`.vpce.amazonaws.com` - Zone-specific VPC endpoint DNS names. Always resolve to private IP addresses.

You can also use the DNS name of the public endpoint `s3vectors.`*`region`*`.api.aws` as the private DNS name of the endpoint service if you have private DNS enabled for the VPC endpoint.

IP addressing for interface endpoints

S3 Vectors regional, zonal, and private DNS endpoints support IPv4, IPv6, and dualstack IP types for AWS PrivateLink. For more information, see IP address types and DNS record IP type for AWS services in the *AWS PrivateLink Guide*.

The following are some things you should know before trying to access S3 Vectors vector indexes and vector buckets over IPv6 in your VPC:

- The client you use to access vectors and your S3 Vectors client must both have dual-stack enabled.
- If your VPC security group doesn't have IPv6 set up, you'll need to configure a rule to allow IPv6 traffic. For more information, see Step 3: Update your security group rules in the *VPC User Guide* and Configure security group rules in the *VPC User Guide*.
- If your VPC doesn't have IPv6 CIDRs assigned, you will need to manually add an IPv6 CIDR block to your VPC. For more information, see Add IPv6 support for your VPC in the *AWS PrivateLink Guide*.
- If you use IP address filtering IAM policies, they must be updated to handle IPv6 addresses. For more information about managing access permissions with IAM, see Identity and Access management in S3 Vectors.

Creating a VPC interface endpoint for S3 Vectors

You can create a VPC interface endpoint for S3 Vectors using the VPC console, AWS CLI, AWS SDKs, or AWS API.

Using the S3 console

1. Open the VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Services**, search for `s3vectors` and select `com.amazonaws.region.s3vectors`.
6. For **VPC**, select the VPC where you want to create the endpoint.
7. (Optional) Under **Additional settings**, for **Enable DNS name**, choose whether to enable the private DNS feature. When enabled, requests that use the public service endpoint (`s3vectors.region.api.aws`), such as requests made through AWS SDKs, resolve to your VPC endpoint instead of the public endpoint.
8. For **Subnets**, select the subnets where you want to create the endpoint network interfaces.
9. For **IP address type**, choose the IP address type for the endpoint:
   - **IPv4**: Assign IPv4 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have IPv4 address ranges.

- **IPv6**: Assign IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets are IPv6 only subnets.
- **Dualstack**: Assign both IPv4 and IPv6 addresses to the endpoint network interfaces. This option is supported only if all selected subnets have both IPv4 and IPv6 address ranges.

10. For **Security groups**, select the security groups to associate with the endpoint network interfaces.
11. (Optional) For **Policy**, you can attach a VPC endpoint policy to control access to S3 Vectors through the endpoint. To allow all operations by all principals on all S3 Vectors resources over the interface endpoint, choose **Full access**. To restrict access, choose **Custom** and enter a policy. For more information, see Control access to VPC endpoints using endpoint policies in the AWS PrivateLink Guide. If you don't attach a policy, the default policy allows full access.
12. Choose **Create endpoint**.

Using the AWS CLI

To create a new VPC endpoint that returns both IPv4 and IPv6 for S3 Vectors, use the following example CLI command. For more information, see create-vpc-endpoint.

```
aws ec2 create-vpc-endpoint \
    --vpc-id vpc-12345678 \
    --service-name com.amazonaws.region.s3vectors \
    --vpc-endpoint-type Interface \
    --subnet-ids subnet-12345678 subnet-87654321 \
    --security-group-ids sg-12345678 \
    --ip-address-type dualstack \
    --private-dns-enabled
```

The `--private-dns-enabled` parameter enables the private DNS feature. When enabled, requests to `s3vectors.region.api.aws` will route through your VPC endpoint.

For more information about creating VPC endpoints, see Create a VPC endpoint in the *VPC User Guide*.

VPC endpoint policies for S3 Vectors

Similar to resource-based policies, you can attach an endpoint policy to your VPC endpoint to control access to vector indexes and vector buckets. For more information about the endpoint policies, see Control access to VPC endpoints using endpoint policies in the AWS PrivateLink Guide.

Example VPC endpoint policies

The following example VPC endpoint policy allows access to all S3 Vectors operations for all principals:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "*",
      "Action": [
        "s3vectors:*"
      ],
      "Resource": "*"
    }
  ]
}
```

The following example VPC endpoint policy restricts access to a specific vector bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "*",
      "Action": [
        "s3vectors:GetVectorBucket",
        "s3vectors:ListIndexes",
        "s3vectors:GetIndex",
        "s3vectors:QueryVectors",
        "s3vectors:GetVectors"
      ],
      "Resource": [
        "arn:aws:s3vectors:us-west-2:111122223333:bucket/amzn-s3-demo-vector-bucket",
        "arn:aws:s3vectors:us-west-2:111122223333:bucket/amzn-s3-demo-vector-bucket/*"
      ]
    }
  ]
}
```

The following example VPC endpoint policy allows access only during business hours using the `aws:CurrentTime` condition key:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "*",
      "Action": "s3vectors:*",
      "Resource": "*",
      "Condition": {
        "DateGreaterThan": {
          "aws:CurrentTime": "08:00Z"
        },
        "DateLessThan": {
          "aws:CurrentTime": "18:00Z"
        }
      }
    }
  ]
}
```

Configuring S3 Vectors clients for VPC endpoints

When using VPC endpoints with S3 Vectors, you can configure your S3 Vectors clients to use either the service DNS name or the VPC endpoint DNS name.

Using the AWS SDKs

SDK for Python (Boto3)

The following example shows how to configure the S3 Vectors client in SDK for Python (Boto3) to use a VPC endpoint:

```
import boto3

# Using service DNS name (requires private DNS feature enabled on VPC endpoint)
s3vectors_client = boto3.client(
    's3vectors',
    region_name='us-west-2',
    endpoint_url='https://s3vectors.us-west-2.api.aws'
)
```

```
# Using VPC endpoint DNS name
s3vectors_client = boto3.client(
    's3vectors',
    region_name='us-west-2',
    endpoint_url='https://vpce-12345678.s3vectors.us-west-2.vpce.amazonaws.com'
)
```

Troubleshooting VPC endpoints

If you're experiencing issues with your interface VPC endpoint, consider the following troubleshooting steps:

- **DNS resolution**: Verify that DNS queries for the endpoint resolve to private IP addresses within your VPC CIDR range when using private DNS.
- **Security groups**: Ensure that the security group associated with the VPC endpoint allows inbound HTTPS traffic (port 443) from your VPC resources.
- **Route tables**: Verify that your subnet route tables don't have conflicting routes that might redirect traffic away from the VPC endpoint.
- **VPC endpoint policy**: Check that your VPC endpoint policy allows the necessary S3 Vectors actions and resources.
- **Client configuration**: If the private DNS feature is disabled, configure your S3 Vectors client to use the VPC endpoint DNS name instead of the service DNS name.

Monitoring VPC endpoint usage

You can monitor your S3 Vectors VPC endpoint usage through CloudTrail NetworkActivity events logs.

For more information about S3 Vectors logging, see Logging with AWS CloudTrail for S3 Vectors.

Logging with AWS CloudTrail for S3 Vectors

Amazon S3 Vectors is integrated with AWS CloudTrail, a service that provides a record of actions that are taken by a user, role, or an AWS service. CloudTrail captures all API calls for S3 Vectors as events. Using the information that's collected by CloudTrail, you can determine the request that was made to S3 Vectors, the IP address from which the request was made, when it was made, and

additional details. When a supported event activity occurs in S3 Vectors, that activity is recorded in a CloudTrail event. You can use CloudTrail trail to log management events and data events for S3 Vectors.

To learn more about CloudTrail, see the CloudTrail User Guide.

S3 Vectors information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in S3 Vectors, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for S3 Vectors, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see Overview for Creating a Trail, Configuring Amazon SNS Notifications for CloudTrail, Receiving CloudTrail Log Files from Multiple Regions, and Receiving CloudTrail Log Files from Multiple Accounts in the *CloudTrail User Guide*.

All S3 Vectors API actions are logged by CloudTrail and are documented in the Amazon S3 Vectors API Reference. For example, calls to the CreateVectorBucket, CreateIndex, and QueryVectors actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element in the *CloudTrail User Guide*.

CloudTrail management events for S3 Vectors

Management events provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

For S3 Vectors, CloudTrail logs the following management events:

- CreateVectorBucket
- DeleteVectorBucket
- GetVectorBucket
- ListVectorBuckets
- PutVectorBucketPolicy
- GetVectorBucketPolicy
- DeleteVectorBucketPolicy
- CreateIndex
- DeleteIndex
- GetIndex
- ListIndexes

The `eventSource` for S3 Vectors management events and data events is `s3vectors.amazonaws.com`.

For more information about management events, see Logging management events in the *CloudTrail User Guide*.

CloudTrail data events for S3 Vectors

Data events provide information about the resource operations performed on or in a resource. These are also known as data plane operations. By default, CloudTrail doesn't log data events. However, you can configure trails to log data events for S3 Vectors resources.

When you configure your trail to log data events, you can specify the S3 Vectors resource type. S3 Vectors supports the following resource types for data events:

- `AWS::S3Vectors::VectorBucket` - Logs data events for all vector indexes in the specified vector buckets

- `AWS::S3Vectors::Index` - Logs data events for specific vector indexes

For S3 Vectors, CloudTrail logs the following data events:

Vector data operations:

- PutVectors - Logs when vectors are added to a vector index
- GetVectors - Logs when vectors are retrieved from a vector index
- DeleteVectors - Logs when vectors are deleted from a vector index
- ListVectors - Logs when vectors in a vector index are listed
- QueryVectors - Logs when similarity queries are performed on a vector index

The `eventSource` for S3 Vectors data events is `s3vectors.amazonaws.com`.

Enabling data event logging for S3 Vectors

You can enable data event logging for S3 Vectors resources when you create or update a CloudTrail trail. You can specify logging for all vector buckets and vector indexes in your account, or you can specify individual vector buckets or vector indexes. For detailed steps about creating a trail, see Creating a trail in the *CloudTrail User Guide*.

To enable data event logging for all S3 Vectors resources:

- When creating or updating a trail, choose **Data events**.
- For **Resource type**, choose `AWS::S3Vectors::VectorBucket`.
- For **Resource ARN**, enter `arn:aws:s3vectors:_:_:bucket/*` to log events for all vector buckets, or specify individual vector bucket ARNs (for example, `arn:aws:s3vectors:`*`us-east-1`*`:`*`123456789012`*`:bucket/`*`amzn-s3-demo-vector-bucket`*).

To enable data event logging for specific vector indexes:

- When creating or updating a trail, choose **Data events**.
- For **Resource type**, choose `AWS::S3Vectors::Index`.
- For **Resource ARN**, enter the ARN of the specific vector index, such as: `arn:aws:s3vectors:`*`us-east-1`*`:`*`123456789012`*`:bucket/`*`amzn-s3-demo-vector-bucket`*`/index/`*`my-index`*.

For more information about data events, see Logging data events in the *CloudTrail User Guide*.

        "clientProvidedHostHeader": "client-host"
    }
}
```

Understanding S3 Vectors log file entries

CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

S3 Vectors CloudTrail log entries contain the following key elements:

- **eventSource** - Always `s3vectors.amazonaws.com` for S3 Vectors events.
- **eventName** - The S3 Vectors API operation that was performed.
- **eventCategory** - Either `Management` for control plane operations or `Data` for data plane operations.
- **readOnly**: `true` for read operations (for examples, GetVectors, QueryVectors, ListVectors) and `false` for write operations (PutVectors, DeleteVectors).
- **resources** - The S3 Vectors resources involved in the operation, including vector buckets and vector indexes.
- **requestParameters** - The parameters that were sent with the request.

- **responseElements** - The response elements returned by the S3 Vectors service.

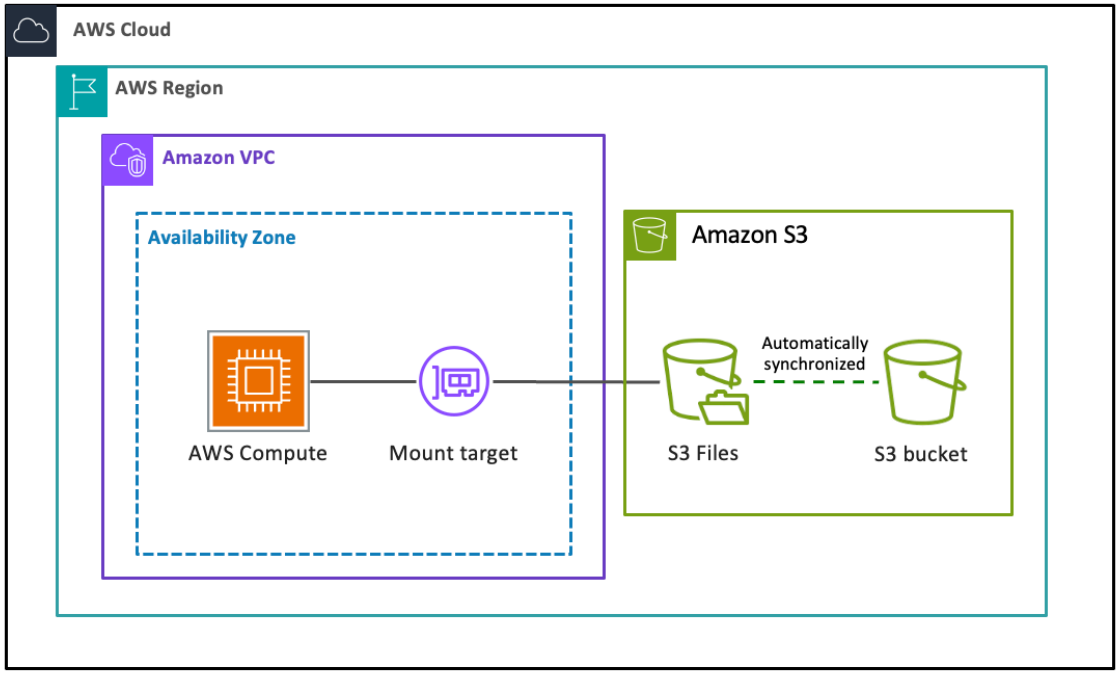
What is S3 Files?

S3 Files is a shared file system that connects any AWS compute resource directly with your data in Amazon S3. It provides fast, direct access to all of your S3 data as files with full file system semantics and low-latency performance, without your data ever leaving S3. Every file-based application, agent, and team can access and work with your S3 data as a file system using the tools they already depend on. Built using Amazon EFS, S3 Files gives you the performance and simplicity of a file system with the scalability, durability, and cost-effectiveness of S3. You can read, write,

and organize data using file and directory operations, while S3 Files manages the synchronization of changes between your bucket and file system.



How does S3 Files work?

When you create an S3 file system linked to your S3 bucket or to a prefix within it and mount it on a compute resource such as an EC2 instance or a Lambda function, S3 Files first presents a traversable view of your bucket's objects as files. As you navigate through directories and open files, associated metadata and contents are placed onto the file system's high-performance storage. When you read files, S3 Files loads file contents onto the high-performance storage on demand without duplicating your entire dataset. When you write data, your writes go to the high-performance storage and are synchronized back to your S3 bucket. S3 Files intelligently translates your file system operations into efficient S3 requests on your behalf. Many read operations bypass the file system entirely, with data served directly from S3.

You can configure the file size threshold for what gets loaded onto the high-performance storage (default <128 KiB), as latencies matter most for small files. S3 Files streams file reads directly from your S3 bucket in two cases: when the file's data is not stored in the file system's high-performance storage, and for large reads >= 1 MiB, even when the data also resides on the file system's high-performance storage. The S3 bucket is optimized for high throughput while the file system's high-performance storage layer is optimized for low-latency access. S3 Files asynchronously imports data for small files (< 128 KiB by default) to the file system's high-performance storage for low latency access on subsequent reads. Recently modified data that has not yet been synchronized to S3 is always served from the file system. For more information, see Customizing synchronization for S3 Files.

Data that has not been read within a configurable window (1 to 365 days, default 30) automatically expires from the high-performance storage. Your authoritative data always remains in S3, and background synchronization keeps the file system and bucket consistent in both directions. For more information, see Understanding how synchronization works.

Supported compute services to mount your S3 file systems are Amazon EC2, AWS Lambda, Amazon EKS, and Amazon ECS. For more information, see Mounting your S3 buckets on compute resources.

Are you a first-time user of S3 Files?

If you are a first-time user of S3 Files, create your first S3 file system using the S3 Console or the AWS CLI by following the Tutorial: Getting started with S3 Files.

Key concepts

The following terms are used throughout S3 Files documentation:

File system

A shared file system linked to your S3 bucket.

High-performance storage

The low-latency storage layer within your file system where actively used file data and metadata reside. S3 Files automatically manages this storage, copying data onto it when you access files and removing data that has not been read within a configurable expiration window. You pay a storage rate for data residing on the high-performance storage.

Synchronization

The process by which S3 Files keeps your active working dataset and your changes consistent between your file system and S3 bucket. Importing copies data from your S3 bucket onto the

file system. Exporting copies changes you make through the file system back to your S3 bucket. S3 Files performs synchronization automatically in both directions.

Mount target

A mount target provides network access to your file system within a single Availability Zone in your VPC. You need at least one mount target to access your file system from compute resources, and you can create a maximum of one mount target per Availability Zone.

Access point

Access points are application-specific entry points to a file system that simplify managing data access at scale for shared datasets. You can use access points to enforce user identities and permissions for all file system requests that are made through the access point. When you create a file system using the AWS Management Console, S3 Files automatically creates one access point for the file system.

Features

High performance without full data replication

S3 Files delivers low-latency file access by copying only your active working set onto the file system's high performance storage, not your entire dataset. Small, frequently accessed files are served from the high-performance storage at sub-millisecond to single-digit millisecond latencies. Large reads are streamed directly from S3 at up to terabytes per second of aggregate throughput. This means you get file system performance for interactive workloads and S3 throughput for streaming workloads, without paying to store or import data you are not using or doesn't benefit from low latency. For more information, see Performance specifications.

Intelligent read routing

S3 Files automatically routes read requests to the storage layer (S3 file system or S3 bucket) best suited for them, while maintaining full file system semantics including consistency, locking, and POSIX permissions. Small, random reads of actively used files are served from the high-performance storage for low latency. Large sequential reads and reads of data not on the file system are served directly from your S3 bucket for high throughput, with no file system data charge.

Automatic synchronization

S3 Files automatically keeps your file system and S3 bucket consistent in both directions. Changes you make through the file system are copied back to your S3 bucket, and changes

made directly to your S3 bucket are reflected in your file system's view. You can customize synchronization behavior, including what data is imported and how long it stays on the file system. For more information, see Understanding how synchronization works.

Scalable performance

S3 Files automatically scales throughput and IOPS to match your workload activity. You do not need to provision or manage performance capacity and you pay only for what you use.

Regional durability

Data written to the high performance storage layer has the same durability as Amazon S3. It stores data redundantly across multiple geographically separated Availability Zones within the same AWS Region, providing high durability and availability for your data.

Encryption

S3 Files encrypts all data in transit using TLS and all data at rest using AWS KMS keys. You can use AWS owned keys (default) or your own customer managed keys. For more information, see Encryption.

File system semantics

S3 Files supports the NFS version 4.2 and 4.1 protocols. It provides file-system-access semantics, such as read-after-write data consistency, file locking, and POSIX permissions.

How are you billed for S3 Files?

You pay a storage rate for the fraction of active data resident on the high-performance storage, and you pay file system access charges for reading from and writing to your file system's high performance storage. S3 Files streams file reads directly from your S3 bucket in two cases: when the file's data is not stored in the file system's high-performance storage, and for large reads >= 1 MiB, even when the data also resides on the file system's high-performance storage. The S3 bucket is optimized for high throughput while the file system's high-performance storage layer is optimized for low-latency access. S3 Files asynchronously imports data for small files (< 128 KiB by default) to the file system's high-performance storage for low latency access on subsequent reads. These reads incur only standard S3 GET request cost with no file system access charge. The file system access charges apply to synchronization operations: importing data onto the file system incurs write charges, and exporting changes back to S3 incurs read charges. For more information, see How S3 Files is metered. For current pricing, see the S3 Files pricing page.

Prerequisites for S3 Files

Before you begin using S3 Files, make sure that you have completed the following prerequisites.

AWS account and compute setup

- You have an AWS account.
- You have a compute resource and an S3 general purpose bucket in your desired AWS Region where you want to create your file system. For more information, see Creating a general purpose bucket.
- Your S3 bucket has versioning enabled. S3 Files requires S3 Versioning to synchronize changes between your file system and your S3 bucket. For more information, see Enabling versioning on buckets.
- Your S3 bucket must use one of the following encryption types: Server-side encryption with Amazon S3 managed keys (SSE-S3) or Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

S3 Files client

To use S3 Files with Amazon EC2, you must install the client `amazon-efs-utils`, a shared open-source collection of tools for Amazon EFS and Amazon S3 Files. To work with S3 Files, you need `amazon-efs-utils` version 3.0.0 or above. The client includes a mount helper program that simplifies mounting S3 file systems and enables Amazon CloudWatch metrics for monitoring your file system's mount status.

Step 1: Install the client

- Access the terminal for your Amazon EC2 instance through Secure Shell (SSH), and log in with the appropriate user name. For more information, see Connect to your EC2 instance in the *Amazon Elastic Compute Cloud User Guide*.
- For those using Amazon Linux, do the following to install efs-utils from Amazon's repositories:

```
sudo yum -y install amazon-efs-utils
```

- If you use other supported Linux distributions, you can do the following:

```
curl https://amazon-efs-utils.aws.com/efs-utils-installer.sh | sudo sh -s -- --
install
```

- For other Linux distributions, see On other Linux distributions in the amazon-efs-utils README on GitHub.

Step 2: Install botocore

The `amazon-efs-utils` client uses botocore to interact with other AWS services. For example, you need to install botocore to use Amazon CloudWatch to monitor your file system. For instructions on installing and upgrading botocore, see Installing botocore in the amazon-efs-utils README on GitHub.

Enabling FIPS mode for S3 Files

If you need to comply with Federal Information Processing Standards (FIPS), then you must enable FIPS mode in the client. Enabling the FIPS mode involves modifying the `s3files-utils.conf` file on the operating system.

Follow these steps to enable FIPS mode in the client for S3 Files:

1. Using your text editor of choice, open the `/etc/amazon/efs/s3files-utils.conf` file.
2. Find the line containing the following text:

```
fips_mode_enabled = false
```

3. Change the text to the following:

```
fips_mode_enabled = true
```

4. Save your changes.

IAM roles and policies

To use S3 Files, you must configure IAM roles and attached policies for two purposes:

- Accessing your bucket from the file system
- Attaching your file system to AWS compute resources

IAM role for accessing your bucket from the file system

When you create an S3 Files file system, you specify an IAM role that S3 Files assumes to read from and write to your S3 bucket. This role grants S3 Files permission to synchronize changes between your file system and your bucket, including Amazon EventBridge rules that trigger synchronization. You must also make sure that your S3 bucket policy does not deny access to your compute resources.

S3 Files requires S3 Versioning on your bucket. It uses version-specific API operations such as `s3:GetObjectVersion` and `s3:GetObjectVersionTagging` in addition to `s3:GetObject`. The following policy uses wildcards (for example, `s3:GetObject*` rather than `s3:GetObject`) to cover both versioned and non-versioned actions.

> **Note**
>
> When you create a file system using the AWS Management Console, S3 Files automatically creates this IAM role with the required permissions.

This IAM role requires the following:

- An inline policy as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3BucketPermissions",
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:ListBucketVersions"
            ],
            "Resource": "arn:aws:s3:::bucket",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": "accountId"
                }
            }
        },
        {
```

```
            "Sid": "S3ObjectPermissions",
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:DeleteObject*",
                "s3:GetObject*",
                "s3:List*",
                "s3:PutObject*"
            ],
            "Resource": "arn:aws:s3:::bucket/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": "accountId"
                }
            }
        },
        {
            "Sid": "UseKmsKeyWithS3Files",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey",
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncryptFrom",
                "kms:ReEncryptTo"
            ],
            "Condition": {
                "StringLike": {
                    "kms:ViaService": "s3.region.amazonaws.com",
                    "kms:EncryptionContext:aws:s3:arn": [
                        "arn:aws:s3:::bucket",
                        "arn:aws:s3:::bucket/*"
                    ]
                }
            },
            "Resource": "arn:aws:kms:region:accountId:*"
        },
        {
            "Sid": "EventBridgeManage",
            "Effect": "Allow",
            "Action": [
                "events:DeleteRule",
                "events:DisableRule",
                "events:EnableRule",
```

```
                "events:PutRule",
                "events:PutTargets",
                "events:RemoveTargets"
            ],
            "Condition": {
                "StringEquals": {
                    "events:ManagedBy": "elasticfilesystem.amazonaws.com"
                }
            },
            "Resource": [
                "arn:aws:events:*:*:rule/DO-NOT-DELETE-S3-Files*"
            ]
        },
        {
            "Sid": "EventBridgeRead",
            "Effect": "Allow",
            "Action": [
                "events:DescribeRule",
                "events:ListRuleNamesByTarget",
                "events:ListRules",
                "events:ListTargetsByRule"
            ],
            "Resource": [
                "arn:aws:events:*:*:rule/*"
            ]
        }
    ]
}
```

Replace the placeholder values with your own values.

#	Placeholder	Description	Example
1	*bucket*	The name of your S3 bucket	my-bucket
2	*region*	The AWS Region of your bucket	us-east-1
3	*accountId*	Your AWS account ID	123456789012

- A trust policy that allows S3 Files to assume the IAM role. Add the following trust policy to the IAM role to allow the S3 Files service to assume it. Replace *accountId* and *region* with your values.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3FilesAssumeRole",
            "Effect": "Allow",
            "Principal": {
                "Service": "elasticfilesystem.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "accountId"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3files:region:accountId:file-system/*"
                }
            }
        }
    ]
}
```

IAM role for attaching your file system to AWS compute resources

Your compute resources on which you mount an S3 file system must have an IAM role attached (for example, an EC2 instance profile) with policies that allow your compute resource to interact with your S3 file system and your source S3 bucket. You must also make sure that the bucket policies of your source bucket don't deny access from your compute resource.

Add the following two policies to the IAM role attached to your compute resource:

- **Permissions for the compute resource to connect to and interact with S3 file systems**

  The IAM role must include permissions for the mount helper to connect to and interact with S3 file systems. You can attach an AWS managed policy such as `AmazonS3FilesClientFullAccess` managed policy if you want to grant the compute resource full read and write access to your S3 file system or the `AmazonS3FilesClientReadOnlyAccess` for read-only access. You can also attach the `AmazonElasticFileSystemsUtils` managed policy if you want to enable Amazon CloudWatch monitoring. For more information and a complete list of available managed

policies for S3 Files, see AWS managed policies for Amazon S3 Files. You can also provide these permissions by adding individual IAM permissions such as `s3files:ClientMount` or `s3files:ClientWrite` (not required for read-only connections) to the IAM role of your compute resource.

- **An inline policy that grants the compute resource read access to S3 objects**

  Add the following inline policy to the IAM role. This policy lets the compute resource read objects directly from the linked S3 bucket in the same account. This improves read performance for large I/O operations. Replace *`bucket`* with your S3 bucket name, or with your bucket name and a prefix to scope access only to the objects that the compute resource needs.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3ObjectReadAccess",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": "arn:aws:s3:::bucket/*"
        },
        {
            "Sid": "S3BucketListAccess",
            "Effect": "Allow",
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::bucket"
        }
    ]
}
```

> **POSIX permissions don't apply to direct S3 access**
>
> This policy grants direct `s3:GetObject` access to the bucket. Reads made directly against Amazon S3 are governed by IAM and bucket policies, not by POSIX permissions. For more information, see the section called “POSIX permissions and direct S3 access”.

Security groups

Once your file system and mount targets are created, you must configure the right security groups to start using your file system. Security groups on both the compute resource and the mount target must allow the required traffic as shown in the table below:

Security group	Rule type	Protocol	Port	Source/destination
EC2 Instance	Outbound	TCP	2049	Mount target security group
Mount Target	Inbound	TCP	2049	EC2 instance security group

Tutorial: Getting started with S3 Files

In this tutorial, you create an S3 file system and mount it on an EC2 instance. You then test basic file operations. You can use either the S3 console or the AWS CLI to get started with S3 Files.

Getting started with S3 Files using the AWS Console

The S3 Files workflow on S3 Console consists of the following steps:

- Create your S3 file system.
- Mount the file system on your EC2 instance and run file system operations.

Prerequisites

Before getting started, make sure you have the following:

- You have completed the AWS account and compute setup.
- You are set up with Amazon EC2 and are familiar with launching EC2 instances. For more information, see Get started with Amazon EC2 in the *Amazon EC2 User Guide*. For this tutorial, use the default VPC for your EC2 instance.
- You have an IAM role for attaching your file system to AWS compute resources attached to your EC2 instance so that it can interact with your S3 file system and your S3 bucket.

Step 1: Create your S3 file system

- Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
- In the navigation bar, verify you are in the AWS Region where your EC2 instance and S3 bucket is.
- In the left navigation pane, choose **General purpose buckets**.
- Select the bucket for which you want to create a file system.
- Choose the **File systems** tab.
- Choose **Create file system**.
- Review and confirm your VPC. For this tutorial, use your default VPC.
- Choose **Create**.

When you create a file system using the AWS Management Console, S3 Files automatically creates one mount target in every Availability Zone in your default VPC and one access point for the file system. This can take a few minutes. Your file system will become available for the next step once all the resources are created.

Step 2: Mount the file system on your EC2 instance

- On the file system **Overview** page, choose **Attach** under **Attach to an EC2 instance**. This will open a new page to mount your file system on an EC2 instance.
- Select your desired EC2 instance from the dropdown **Available EC2 instances**.
- Enter a path on your EC2 instance where you want to mount the file system. For example, `/mnt/s3files/`.
- Make sure you have configured the right Security groups on your EC2 instance and the mount target to allow the required traffic to flow.
- Make sure you have the right IAM role with required permissions attached to your EC2 instance so that it can interact with your S3 file system and your S3 bucket. For more information, see IAM role for attaching your file system to AWS compute resources. For this tutorial, you can consider giving the client full access by adding the managed policy `AmazonS3FilesClientFullAccess` to EC2 instance's IAM role.
- Follow the attach instructions displayed on the page to open CloudShell, mount your file system, and run basic file system operations.

Getting started with S3 Files using the AWS CLI

The S3 Files workflow on AWS CLI consists of the following steps:

1. Create your file system.
2. Create mount targets for your file system.
3. Mount the file system on your EC2 instance using a mount target.
4. Test file operations such as listing a directory, writing text to a file, reading a file, and copying a file. Then verify that your changes reflect in your S3 bucket.

Prerequisites

Before getting started, make sure you have the following:

- You have installed and configured the AWS CLI. For more information, see Installing or updating to the latest version of the AWS CLI.
- You have completed all the prerequisites described in Prerequisites for S3 Files.
- You are set up with Amazon EC2 and are familiar with launching EC2 instances. You need an AWS account, a user with administrative access, a key pair, and a security group. For more information, see Get started with Amazon EC2 in the *Amazon EC2 User Guide*.

Step 1: Create your S3 file system

Connect to your EC2 instance. Run the `create-file-system` command to create a file system.

```
aws s3files create-file-system --region aws-region --bucket bucket-arn --role-arn iam-role
```

Replace the following with your desired values:

- *`aws-region`* : The AWS Region of your bucket. For example, `us-east-1`.
- *`bucket-arn`* : The ARN of your S3 bucket.
- *`iam-role`* : ARN of the IAM role that S3 Files assumes to read from and write to your S3 bucket. Make sure you have added the right permissions to this IAM role. For more information, see IAM role for accessing your bucket from the file system.

After successfully creating the file system, S3 Files returns the file system description as JSON. Note down the file system ID for the next step.

Step 2: Create mount targets

A mount target provides network access to your file system in your VPC within a single Availability Zone. You need a mount target to access your file system from compute resources. You can create a maximum of one mount target per Availability Zone. We recommend creating a mount target in every Availability Zone you operate in.

Run the following `create-mount-target` command to create a mount target for your file system. You must make sure the *`subnet-id`* is in the same VPC as your EC2 instance. You must create your mount target in the same Availability Zone as your EC2 instance.

```
aws s3files create-mount-target --region aws-region --file-system-id file-system-id --
subnet-id subnet-id
```

Here *`file-system-id`* is the file system ID that you received in the response of `create-file-system` command. Mount targets can take up to ~5 minutes to create.

Step 3: Mount the file system on your EC2 instance

Before mounting your file system, make sure you have configured the right Security groups on your compute resource and the mount target to allow the required traffic to flow. For more details on security groups, visit the VPC user guide.

Run the following commands to mount your file system:

- Create a directory `/mnt/s3files` that you will use as the file system mount point using the following command:

  ```
  sudo mkdir /mnt/s3files
  ```

- Mount the file system:

  ```
  sudo mount -t s3files file-system-id:/ /mnt/s3files
  ```

If you don't have your file system ID, you can find it by running the following:

```
aws s3files get-file-system --region aws-region --file-system-id file-system-id
```

Step 4: Test file operations

Test basic file operations on your mounted file system as follows:

- Change to the directory you mounted:

  ```
  cd /mnt/s3files
  ```

- You can list the contents of your directory to check that the contents of your source bucket or prefix got imported. Synchronization typically occurs within seconds, but may take longer, especially for the first file. If your bucket is empty, the command below will also return an empty result.

  ```
  ls
  ```

- You can also test other file operations:
  - Create a file:

    ```
    echo "Hello, S3 Files!" > test.txt
    ```

  - Read the file:

    ```
    cat test.txt
    ```

  - Create a directory:

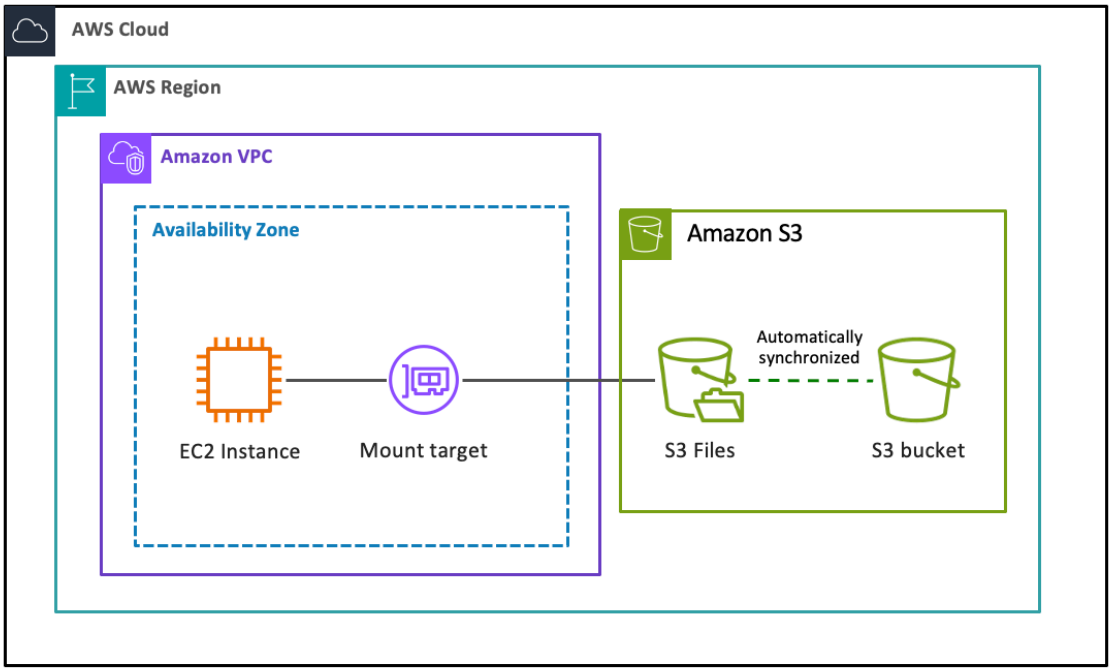
    ```
    mkdir test-directory
    ```

  - Copy the file to the directory:

    ```
    cp /mnt/s3files/test.txt /mnt/s3files/test-directory/
    ```

You can then go to your S3 bucket and check that the directory `test-directory` reflects in your bucket. Note that it may take ~1 minute to synchronize changes back to your S3 bucket.

Mounting your S3 buckets on compute resources



You can mount an S3 file system on compute resources to access your S3 data as files. Your compute resource must run in the same Amazon Virtual Private Cloud (Amazon VPC) as the S3 file system. All compute resources communicate with the file system through mount targets on NFS port 2049.

S3 Files supports the following compute environments:

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- AWS Lambda functions
- Amazon Elastic Kubernetes Service (Amazon EKS) clusters
- Amazon Elastic Container Service (Amazon ECS) clusters

Mounting S3 file systems on Amazon EC2

To mount S3 file systems on an EC2 instance, you must use the S3 Files mount helper. The mount helper helps you mount your S3 file systems on EC2 instances running the supported distributions. When mounting a file system, the mount helper defines a new network file system type, called `s3files`, which is fully compatible with the standard `mount` command in Linux. The mount helper also supports mounting an S3 file system at instance boot time automatically by using entries in the `/etc/fstab` configuration file on EC2 Linux instances. The mount helper is part of the open-source collection of tools that is installed when you install the S3 Files client (amazon-efs-utils).

Prerequisites to mount on EC2 instances

- Your EC2 instance runs one of the following supported Linux distributions. Windows and macOS are not supported.
  - Amazon Linux 2
  - Amazon Linux 2023
  - Red Hat Enterprise Linux (RHEL) 8
  - Red Hat Enterprise Linux (RHEL) 9
  - Ubuntu 20.04
  - Ubuntu 22.04
  - Ubuntu 24.04
  - openSUSE Leap
  - SUSE Linux Enterprise Server (SLES) 15
- You have an S3 file system with at least one mount target available.
- Your EC2 instance is in the same Availability Zone as the mount target that you will use to mount your file system.
- An IAM instance profile is attached to the EC2 instance with the required permissions for S3 Files. For details, see IAM role for attaching your file system to AWS compute resources.

- You have configured the required Security groups.
- You have installed the amazon-efs-utils package on the EC2 instance. For more information, see S3 Files client.

How does the mount helper work?

When you issue a mount command, the mount helper performs the following actions:

- Retrieves IAM credentials from the EC2 instance profile.
- Initializes the efs-proxy process to establish a TLS-encrypted connection to the mount target.
- Starts the amazon-efs-mount-watchdog supervisor process, which monitors the health of TLS mounts. This process is started automatically the first time an S3 file system is mounted.
- Mounts the file system at the specified mount point.

The mount helper uses TLS version 1.2 to communicate with your file system. Using TLS requires certificates, and these certificates are signed by a trusted Amazon Certificate Authority. For more information on how encryption works, see Security for S3 Files.

The mount helper uses the following mount options that are optimized for S3 Files:

Option	Value	Description
`nfsvers`	4.2	NFS protocol version.
`rsize`	1048576	Sets the maximum number of bytes of data that the NFS client can receive for each network READ request to 1048576 (1 MB), the largest available, to avoid diminished performance.
`wsize`	1048576	Sets the maximum number of bytes of data that the NFS client can send for each network WRITE request to 1048576 (1 MB), the largest available, to avoid diminished performance.
`hard`	—	Sets the recovery behavior of the NFS client after an NFS request times out, so that NFS requests are retried indefinitely until the server replies, to ensure data integrity.

Option	Value	Description
`timeo`	600	Sets the timeout value that the NFS client uses to wait for a response before it retries an NFS request to 600 deciseconds (60 seconds) to avoid diminished performance.
`retrans`	2	Sets the number of times the NFS client retries a request before it attempts further recovery action to 2.
`noresvport`	—	Tells the NFS client to use a new non-privileged TCP source port when a network connection is reestablished. Using `noresvport` helps ensure that your file system has uninterrupted availability after a reconnection or network recovery event.

In addition, the mount helper automatically uses `tls` and `iam` mount options when mounting an S3 file system as S3 Files requires these options to establish a connection. This is because S3 Files always mounts a file system using TLS encryption and IAM authentication and these cannot be disabled.

How to mount your S3 file system on an EC2 instance?

- Connect to your EC2 instance through Secure Shell (SSH) or EC2 Instance Connect on EC2 Console. For more information, see Connect to your EC2 instance.
- Create a directory `/mnt/s3files` that you will use as the file system mount point using the following command:

```
sudo mkdir /mnt/s3files
```

- Mount your S3 file system:

```
FS="{YOUR_FILE_SYSTEM_ID}"
sudo mount -t s3files $FS:/ /mnt/s3files
```

- Confirm the file system is mounted.

```
df -h /mnt/s3files
```

You should see a response similar to the following:

```
Filesystem      Size  Used Avail Use% Mounted on
{s3files-dns}    8.0E  129M  8.0E   1% {path/to/mount}
```

You can also verify file system mount and inspect mount options by listing the contents of the local mount point. If the mount is successful, this command shows the mount details, including your mount options, for the specific directory.

```
findmnt -T /mnt/s3files
```

For detailed information on mount commands, visit the GitHub documentation.

You can now read and write S3 objects as files on your local mount path using standard file system operations. If you have objects in your S3 bucket then you can view them as files using the following commands.

```
ls /mnt/s3files
```

You can monitor your file system storage, performance, client connections, and synchronization errors using CloudWatch metrics.

How to mount your S3 file system on an EC2 instance using access points

When you mount a file system using an access point, the mount command includes the `access-point-id` mount option.

```
sudo mount -t s3files -o accesspoint=access-point-id file-system-id /mnt/s3files
```

where:

- *`access-point-id`* is the ID of your access point.
- *`file-system-id`* is the ID of your S3 file system.

Automatically mounting S3 file systems when your EC2 instance starts

You can configure your EC2 instance to automatically mount an S3 file system when the instance starts or restarts by updating the `/etc/fstab` file. The `/etc/fstab` file contains information about file systems and is used by the operating system to determine which file systems to mount at boot time.

> **Warning**
>
> Use the `_netdev` option, used to identify network file systems, when mounting your file system automatically. If `_netdev` is missing, your EC2 instance might stop responding. This result is because network file systems need to be initialized after the compute instance starts its networking. For more information, see Automatic mounting fails and the instance is unresponsive.

You can use the mount helper to configure an Amazon EC2 instance to automatically mount an S3 file system when the instance starts:

- Update the EC2 `/etc/fstab` file with an entry for the S3 file system.
- Attach an S3 file system when you create a new EC2 instance using the EC2 launch instance wizard.

Updating the /etc/fstab file

Perform the following steps to update the `/etc/fstab` on an EC2 Linux instance so that the instance uses the mount helper to automatically remount an S3 file system when the instance restarts.

- Connect to your EC2 instance.
- Open the `/etc/fstab` file in an editor and add the following line to the file:

```
file-system-id:/ mount-directory s3files _netdev 0 0
```

Where:

- *`file-system-id`* is the ID of your S3 file system (for example, `fs-0123456789abcdef0`).

- *mount-directory* is the mount point directory on your EC2 instance (for example, /mnt/s3files).
- _netdev specifies that the file system is a network file system, ensuring the instance waits for network availability before attempting the mount.

- Save the file and close the editor.
- Test the fstab entry by mounting all file systems in fstab:

```
sudo mount -a
```

- Verify the file system is mounted:

```
findmnt -T mount-directory
```

Using the nofail option

We recommend adding the nofail option to your fstab entry in production environments. This option allows the instance to boot even if the file system fails to mount:

```
file-system-id:/ mount-directory s3files _netdev,nofail 0 0
```

Automatic mounting with an access point

To automatically mount using an S3 Files access point, include the accesspoint option:

```
file-system-id:/ mount-directory s3files _netdev,accesspoint=access-point-id 0 0
```

Automatic mounting with a subdirectory

To automatically mount a specific subdirectory of your file system, specify the path:

```
file-system-id:/path/to/directory mount-directory s3files _netdev 0 0
```

Using the EC2 launch instance wizard

- Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
- Choose **Launch Instance**.

- Follow this documentation to launch an EC2 instance using the launch instance wizard in the AWS console. Before choosing **Launch Instance**, configure your network and add your S3 file system as shown in following steps.
- Make sure you select a subnet in your **Network settings**.
- Select the default security group to make sure that your EC2 instance can access your S3 file system. You can't access your EC2 instance by Secure Shell (SSH) using this security group. For access by SSH, later you can edit the default security and add a rule to allow SSH or a new security group that allows SSH. You can use the following settings:
  - Type: SSH
  - Protocol: TCP
  - Port Range: 22
  - Source: Anywhere 0.0.0.0/0
- Under **Storage** section, choose **File systems** and choose **S3 Files**.
- Under the file system drop down, you will see your file systems in the Availability Zone based on the subnet you selected previously in your Network settings. Choose the S3 file system that you want to mount. If you don't have any file systems, choose create a new file system to create a new one.
- Enter a local mount path on your EC2 instance where you want to mount the file system (for example, `/mnt/s3files`).
- A command will be generated to mount the file system and add it to fstab. You can choose to add the command to User data or run it manually on your EC2 instance after it is launched. Your EC2 instance will then be configured to mount the S3 file system at launch and whenever it's rebooted.
- Choose **Launch Instance**.

Mounting S3 file systems from another VPC

When you use a VPC peering connection or transit gateway to connect VPCs, Amazon EC2 instances that are in one VPC can access S3 file systems in another VPC.

A transit gateway is a network transit hub that you can use to interconnect your VPCs and on-premises networks. For more information about using VPC transit gateways, see Getting Started with transit gateways in the *Amazon VPC Transit Gateways Guide*. A VPC peering connection is a networking connection between two VPCs. This type of connection enables you to route traffic between them using private Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6)

addresses. You can use VPC peering to connect VPCs within the same AWS Region or between AWS Regions. For more information on VPC peering, see What is VPC Peering? in the *Amazon VPC User Guide*.

When mounting a file system from a different VPC, you need to resolve the mount target manually. You should use the IP address of the mount targets in the corresponding Availability Zone as follows and replace the *mount-target-ip-address*, *file-system-id*, and *mount-directory* with your values.

```
sudo mount -t s3files -o mounttargetip=mount-target-ip-address file-system-id mount-directory
```

To ensure high availability of your file system, we recommend that you always use a mount target IP address that is in the same Availability Zone as your NFS client.

Alternatively, you can use Amazon Route 53 as your DNS service. In Route 53, you can resolve the mount target IP addresses from another VPC by creating a private hosted zone and resource record set. For more information on how to do so, see Working with private hosted zones in the *Amazon Route 53 Developer Guide*.

For more details on mounting from another VPC, visit the GitHub ReadMe.

Mounting S3 file systems from a different AWS Region

If you are mounting your S3 file system from another VPC that is in a different AWS Region than the file system, you will need to edit the `s3files-utils.conf` file. In `/etc/amazon/efs/s3files-utils.conf`, locate the following lines:

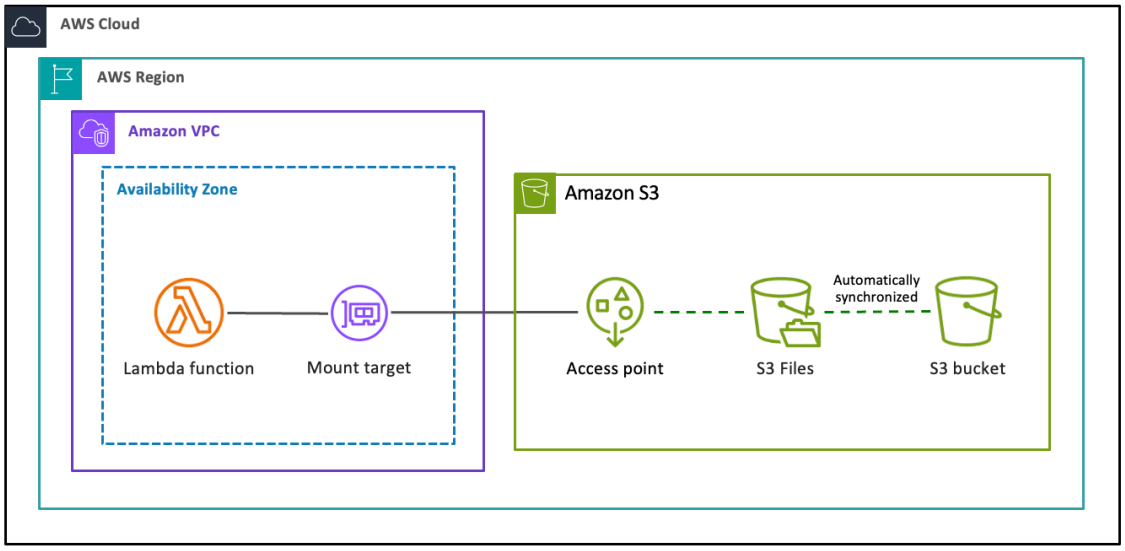
```
#region = us-east-1
```

Uncomment the line, and replace the value for the ID of the region in which the file system is located, if it is not in us-east-1.

Then, you need to specify the mount target IP in the mount command after changing the region in the config:

```
sudo mount -t s3files -o mounttargetip=mount-target-ip-address file-system-id mount-directory
```

Unmounting your S3 file system



To unmount an S3 file system connected to an EC2 instance running Linux, use the `umount` command as follows:

```
umount mount-directory
```

We recommend that you do not specify any other `umount` options. Avoid setting any other `umount` options that are different from the defaults. You can verify that your S3 file system has been unmounted by running the `findmnt` command. If the unmount was successful, the `findmnt` command on your mount directory will yield no output.

Mounting S3 file systems on AWS Lambda functions

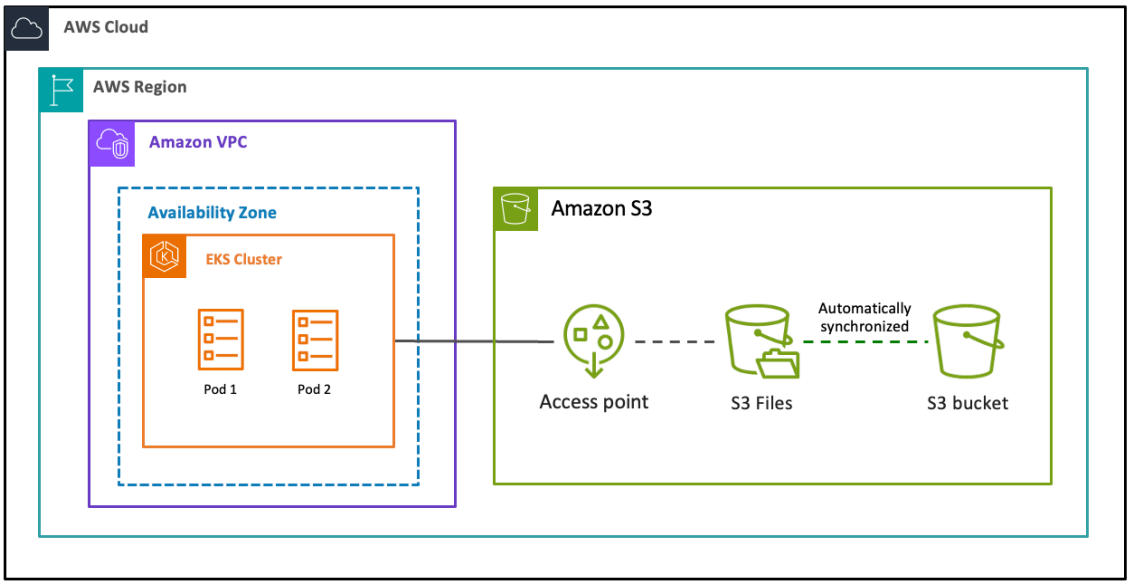
While AWS Lambda functions provide an ephemeral local storage available during execution, many serverless workloads, such as machine learning inference, data processing, and content management, require access to large reference datasets, shared files, or persistent storage. By attaching an S3 file system to your Lambda function, you can easily share data across function invocations, read large reference data files, and write function output to a persistent and shared store, all through a local mount path.

Prerequisites

Before you mount an S3 file system on a Lambda function, make sure that you have the following:

- **File system, mount targets, and access point** — The S3 file system, at least one mount target, and one access point must be available. If you create a file system using the AWS Management Console, S3 Files automatically creates one mount target in every Availability Zone in your default VPC and one access point (UID/GID 1000/1000 and `/Lambda` as the access point scope) for the file system.
- **Lambda function** — A Lambda function with an execution role that has access to mount the file system. See Execution role and user permissions in the *AWS Lambda User Guide*.
- **VPC** — The Lambda function must be in the same VPC as your mount target. The subnets you assign to your Lambda function must be in the Availability Zone that has a mount target.
- You have configured the required Security groups.

How to mount your S3 file system on a Lambda function



- On the S3 Console, choose **File systems** in the left navigation pane.
- Select the file system you want to mount on your Lambda function.
- In the **Overview** tab, choose **Attach** under **Attach to a Lambda function**.
- Select an available Lambda function from the drop down. The available list only shows functions within the same VPC and subnets where you have a mount target.
- Specify the local mount path.
- If you have more than one access points, select an access point.
- Choose **Attach**. Your file system will now be attached the next time you invoke your Lambda function.

For more details, see Configuring Amazon S3 Files access with AWS Lambda.

You can monitor your file system storage, performance, client connections, and synchronization errors using Amazon CloudWatch.

Mounting S3 file systems on Amazon EKS

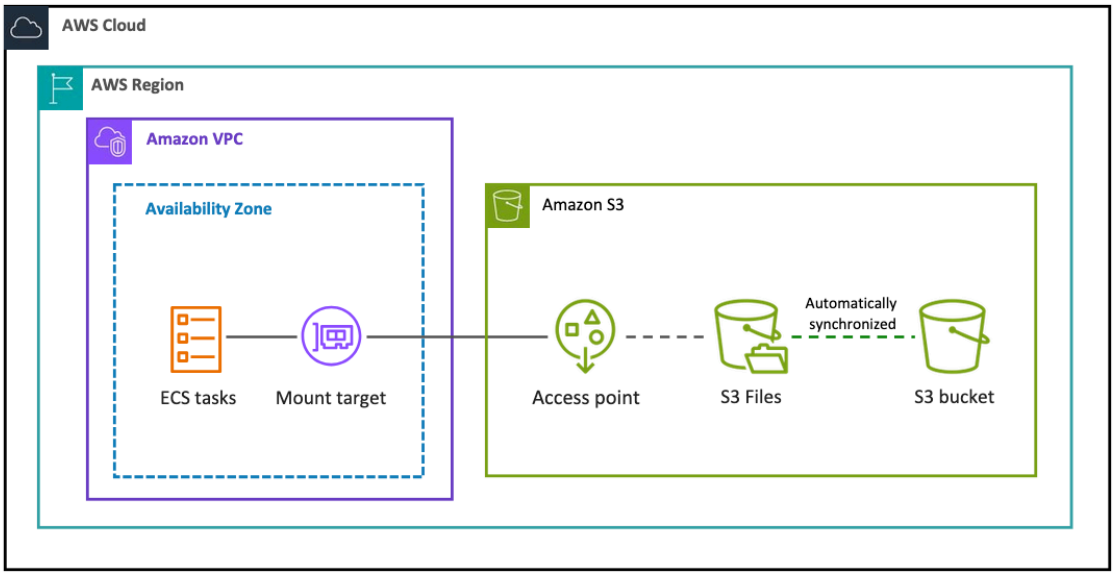
You can attach an S3 file system to an Amazon EKS cluster by using the Amazon EFS Container Storage Interface (CSI) driver. The driver supports both dynamic and static provisioning. To set this up, install the efs-csi-driver, which is the CSI driver for both Amazon EFS and S3 Files.

Prerequisites

Before you mount an S3 file system on an EKS cluster, make sure that you have the following:

- You have an S3 file system that has at least one mount target available.
- You have configured the required Security groups.
- Your EKS cluster must be in the same VPC as your mount target.
- The Amazon EFS CSI driver needs AWS Identity and Access Management (IAM) permissions to connect to and interact with S3 file systems. For details, see IAM role for attaching your file system to AWS compute resources.
- AWS suggests using EKS Pod Identities. For more information, see Overview of setting up EKS Pod Identities.
- For information about IAM roles for service accounts and setting up an IAM OpenID Connect (OIDC) provider for your cluster, see Create an IAM OIDC provider for your cluster.
- The `kubectl` command line tool is installed on your device or AWS CloudShell. The version must be within one minor version of the Kubernetes version of your cluster. For example, if your cluster version is 1.29, you can use `kubectl` version 1.28, 1.29, or 1.30 with it. To install or upgrade `kubectl`, see Set up kubectl and eksctl.

How to mount your S3 file system on an EKS cluster



The Amazon EFS CSI driver requires IAM permissions to interact with your file system. Create an IAM role and attach the `AmazonS3FilesCSIDriverPolicy` managed policy to it. Then add the EFS CSI driver to your EKS cluster and specify the IAM role. You can use the AWS Management Console or the AWS API. For details, see Using S3 file system storage with Amazon EKS.

You can also use S3 file systems with AWS Batch on Amazon EKS. To attach an S3 file system volume to your AWS Batch job, use Amazon EKS pods with a persistent volume claim. For more details, see persistentVolumeClaim section of Register Job Definitions and EKS Persistent Volume Claim pages of the *AWS Batch API Reference Guide*.

You can monitor your file system storage, performance, client connections, and synchronization errors using Amazon CloudWatch.

Mounting S3 file systems on Amazon ECS

You can attach an S3 file system to an Amazon ECS task definition and then deploy the task to access your S3 data from your containers.

In Amazon ECS, S3 Files volume support is available for AWS Fargate and ECS Managed Instances at General Availability. S3 Files volumes are not supported on the Amazon EC2 launch type. If you configure an S3 Files volume in a task definition and attempt to run it on the EC2 launch type, the task will fail.

Prerequisites

Before you attach an S3 file system to an ECS task, make sure that you have the following:

- You have an S3 file system with at least one mount target in available state.
- The ECS task must be in the same VPC as the mount target.
- Add the permissions to your ECS task IAM role to access S3 file systems. For details, see IAM role for attaching your file system to AWS compute resources.
- You have configured the required Security groups.

How to mount your S3 file system on an ECS task

- On the S3 Console, choose **File systems** in the left navigation pane.
- Select the file system you want to mount.
- In the **Overview** tab, choose **Attach** under **Attach to an ECS task**.
- Select your desired ECS task definition from the drop down.
- Specify the local mount path.
- You can optionally specify an access point, a root directory, and a transit encryption port.
- Once the file system is attached in the task definition, you can start a task using this task definition in following ways:
  - You can deploy the task as a standalone, one-time run. For details, see Running an application as an Amazon ECS task in the *Amazon ECS Developer Guide*.
  - You can also deploy the task definition as a service. For details, see View service history using Amazon ECS service deployments in the *Amazon ECS Developer Guide*.

For details, see Using S3 file system storage with Amazon ECS.

You can monitor your file system storage, performance, client connections, and synchronization errors using Amazon CloudWatch.

Tutorial: Mount an S3 file system across accounts

You can access an S3 file system from compute resources in a different AWS account than the file system owner account. This is called cross-account access. With cross-account access, teams in different accounts can share the same file system without duplicating data.

Cross-account access requires the following:

- Network access on port 2049
- DNS that resolves the file system mount target
- S3 Files permissions that allow access from the remote account

In this tutorial, you configure cross-account access from an Amazon EC2 instance using the AWS Management Console. Account A owns the S3 file system, and Account B owns the EC2 instance that connects to it.

Prerequisites

Before you begin, make sure that you have the following:

- An S3 file system with mount targets in Account A. For more information, see Getting started with S3 Files.
- An EC2 instance running in Account B with amazon-efs-utils v3.0.0 or later.
- An IAM role for attaching your file system to AWS compute resources attached to your EC2 instance.
- A file system policy that grants Account B permissions for `s3files:ClientMount` and `s3files:ClientWrite`.
- Non-overlapping VPC CIDRs in Account A and Account B.
- Both accounts meet all S3 Files prerequisites. For more information, see S3 Files prerequisites.

Example values used in this tutorial

This tutorial uses the following example values. Replace them with your own values.

Item	Value
Account A (S3 Files account)	`111111111111`
Account B (EC2 instance account)	`222222222222`
S3 file system ID	`fs-0123456abcdef0189`
Region	`us-east-1`

Item	Value
S3 Files DNS name	*{az_id}*.fs-0123456abcdef0189.s3files.us-east-1.on.aws
EC2 instance role (Account B)	ec2-instance-role

Step 1: Record file system network details

In Account A, record the following network details from your file system.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose **General purpose buckets**, then choose the bucket linked to your S3 file system.
3. Choose the **File systems** tab, choose your file system, then choose the **Mount targets** tab.
4. Verify that mount targets exist in each Availability Zone you plan to connect from.
5. Record the following values for use in later steps:
   - VPC ID of the file system
   - AZ IDs (for example, `use1-az1`, `use1-az2`)
   - IPv4 address of each mount target (mapped to each AZ ID)
   - Security group ID of the mount targets

Step 2: Create a VPC peering connection

> ⚠ **CIDR ranges must not overlap**
>
> VPC peering requires that your CIDR ranges do not overlap. Verify this before proceeding.

1. In both accounts, verify that the VPC has the following DNS settings enabled. In the VPC console, choose your VPC, then choose **Edit VPC settings**:
   - **DNS resolution (enableDnsSupport):** Enabled
   - **DNS hostnames (enableDnsHostnames):** Enabled
2. In Account B, open the VPC console, choose **Peering Connections**, then choose **Create peering connection**. Enter the following values:

- **VPC ID (Requester):** VPC of the EC2 instance (Account B)
- **Account:** Another Account, then enter `111111111111`
- **Region:** `us-east-1`
- **VPC ID (Accepter):** VPC of the S3 file system (Account A)

3. In Account A, open the VPC console, choose **Peering Connections**, find the pending request, then choose **Actions**, **Accept request**. Verify that the status changes to **Active**.

Step 3: Add routes

In Account B (EC2 instance account):

1. Open the VPC console, choose **Route Tables**, and select the route table for the EC2 instance's subnet.
2. Choose **Edit routes**, then choose **Add route**:
   - **Destination:** CIDR of the S3 Files VPC in Account A
   - **Target:** Select **Peering Connection**, then select the peering connection you created in Step 2

In Account A (S3 Files account):

1. Open the VPC console, choose **Route Tables**, and select the route table for the S3 Files VPC.
2. Choose **Edit routes**, then choose **Add route**:
   - **Destination:** CIDR of the EC2 instance VPC in Account B
   - **Target:** Select **Peering Connection**, then select the peering connection you created in Step 2

Step 4: Configure security groups

The mount target security group in Account A must allow inbound NFS traffic from the EC2 instance in Account B. The EC2 instance security group in Account B must allow outbound NFS traffic to the mount target.

1. In the VPC console, choose **Security Groups**, then select the mount target security group you noted in Step 1.
2. Choose **Edit inbound rules** and add the following rule:
   - **Type:** NFS

- **Port:** 2049
- **Source:** Choose **Custom**, then enter the EC2 security group ID from Account B

3. Verify that the EC2 instance security group in Account B allows outbound TCP on port 2049.

Security Group	Rule Type	Protocol	Port	Source/Destination
EC2 instance (Account B)	Outbound	TCP	2049	Mount target security group (Account A)
Mount target (Account A)	Inbound	TCP	2049	EC2 instance security group (Account B)

Step 5: Add a file system policy

In Account A, add a file system policy that grants the Account B role permission to mount. S3 Files evaluates this policy on every mount request. The mount fails without it, regardless of network or DNS configuration.

1. Open the Amazon S3 console, choose your bucket, then choose the **File systems** tab.
2. Select your file system, then choose **Edit file system policy**.
3. Add a policy that grants the Account B role permission to mount. The following example policy grants `s3files:ClientMount` and `s3files:ClientWrite` to the EC2 instance role in Account B:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCrossAccountMount",
            "Effect": "Allow",
            "Principal": { "AWS": "arn:aws:iam::222222222222:role/ec2-instance-
role" },
            "Action": [
                "s3files:ClientMount",
                "s3files:ClientWrite"
            ],
```

```
            "Resource": "arn:aws:s3files:us-east-1:111111111111:file-system/
fs-0123456abcdef0189"
        }
    ]
}
```

Step 6: Create Route 53 hosted zones

In Account B, create private hosted zones so the EC2 instance can resolve the file system DNS names. S3 Files uses DNS names in the following format to route mount requests to the correct Availability Zone:

```
{az_id}.{fs_id}.s3files.{region}.on.aws
```

Create one private hosted zone for each AZ ID that has a mount target. For each AZ ID:

1. Open the Route 53 console, choose **Hosted Zones**, then choose **Create hosted zone**. Enter the following values:
   - **Domain name:** *{az_id}*`.fs-0123456abcdef0189.s3files.us-east-1.on.aws`
   - **Type:** Private hosted zone
   - **Region:** `us-east-1`
   - **VPC ID:** VPC of the EC2 instance in Account B
2. Choose **Create hosted zone**.
3. Choose **Create record** and enter the following values:
   - **Record name:** (leave blank)
   - **Record type:** A
   - **Value:** IPv4 address of the mount target for that AZ ID (from Step 1)
4. Choose **Create records**.
5. Repeat for all AZ IDs that you plan to connect from.

Example:

Hosted Zone Domain Name	A Record Value
use1-az1.fs-0123456abcdef0189.s3files.us-east-1.on.aws	Mount target IP for use1-az1
use1-az2.fs-0123456abcdef0189.s3files.us-east-1.on.aws	Mount target IP for use1-az2
use1-az4.fs-0123456abcdef0189.s3files.us-east-1.on.aws	Mount target IP for use1-az4

Step 7: Configure IAM permissions

Attach an IAM role to the EC2 instance in Account B. The role must include the following permissions to mount and access the file system:

- **The `AmazonS3FilesClientFullAccess` managed policy (or equivalent)** — This policy grants the EC2 instance permission to connect to and interact with S3 Files file systems.
- **An inline policy granting S3 object access to the cross-account bucket** — This policy grants the EC2 instance permission to read objects directly from the S3 bucket in Account A.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3ObjectReadAccess",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": "arn:aws:s3:::BUCKET_NAME_ACCOUNT_A/*"
        },
        {
            "Sid": "S3BucketListAccess",
            "Effect": "Allow",
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::BUCKET_NAME_ACCOUNT_A"
        }
```

```
    ]
}
```

Replace *BUCKET_NAME_ACCOUNT_A* with the name of the S3 bucket in Account A.

> **Note**
>
> For the complete list of required base policies for your compute resource, see IAM role for attaching your file system to AWS compute resources.

Step 8: Mount the file system

Connect to your EC2 instance in Account B and run the following commands.

1. Create a mount point:

```
sudo mkdir /mnt/s3files
```

2. Mount the file system:

```
sudo mount -t s3files fs-0123456abcdef0189 /mnt/s3files
```

3. Verify the mount:

```
df -h /mnt/s3files
ls /mnt/s3files
```

Troubleshooting

Use the following information to resolve common issues when mounting an S3 file system across accounts.

Mount fails with a DNS resolution error

Verify that both VPCs have `enableDnsSupport` and `enableDnsHostnames` enabled. Verify that the Route 53 private hosted zones are associated with the correct VPC in Account B and that A records point to the correct mount target IP addresses.

Mount hangs or times out

Verify that the VPC peering connection status is **Active**. Verify that route tables in both accounts have entries for the peer VPC CIDR pointing to the peering connection. Verify that the mount target security group allows inbound TCP on port 2049 from the EC2 instance security group.

Permission denied on file operations

Verify that the EC2 instance IAM role has both the `AmazonS3FilesClientFullAccess` managed policy and the inline S3 object access policy attached. Verify that the file system policy in Account A grants `s3files:ClientMount` and `s3files:ClientWrite` to the Account B role.

Creating and managing S3 Files resources

This page describes how to create, configure, and manage S3 Files resources. To manage your resources using the AWS CLI, see S3 Files API reference.

File systems

A shared file system linked to your S3 bucket. It stores a fraction of your actively used S3 data as files and directories so that your applications and users can benefit from low-latency performance. You can access your data using standard file system operations, including reading, writing, and locking files.

- Creating file systems
- Deleting file systems

Mount targets

A mount target provides network access to your file system within a single Availability Zone in your VPC. You need at least one mount target to access your file system from compute resources, and you can create a maximum of one mount target per Availability Zone. We recommend creating one mount target in each Availability Zone you operate in so that your compute resources always have a local network path to the file system, improving both availability and latency. When you create a file system using the AWS Management Console, S3 Files automatically creates one mount target in every Availability Zone in your default VPC.

- Creating mount targets
- Managing mount targets

- Deleting mount targets

File system policies

A file system policy is an optional IAM resource policy that you can create for your S3 file system to control NFS client access to the file system.

- Creating file system policies
- Deleting file system policies

Access points

Access points are application-specific entry points to a file system that simplify managing data access at scale for shared datasets. You can use access points to enforce user identities and permissions for all file system requests that are made through the access point. Additionally, access points can restrict clients to only access data within a specified root directory and its subdirectories. When you create a file system using the AWS Management Console, S3 Files automatically creates one access point for the file system.

A file system can have a maximum of 25,000 access points. For more information, see Unsupported features, limits, and quotas.

- Creating access points for an S3 file system
- Deleting access points for an S3 file system

Tags

Tags are key-value pairs that you define and associate with your S3 Files resources to help organize, identify, and manage them.

- Tagging S3 Files resources

CloudFormation template

You can also use CloudFormation templates to create and manage S3 Files resources. See Amazon Simple Storage Service Files (Amazon S3 Files) in the *AWS CloudFormation User Guide* for all available S3 Files resource types.

Topics

- Creating file systems
- Deleting file systems
- Creating mount targets

- Managing mount targets
- Deleting mount targets
- Creating file system policies
- Deleting file system policies
- Creating access points for an S3 file system
- Deleting access points for an S3 file system
- Tagging S3 Files resources

Creating file systems

You can create file systems by using the AWS Console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API for any existing or new S3 general purpose bucket. For information on creating a new bucket, see Creating a general purpose bucket.

Required IAM permissions for creating file systems

When you create an S3 file system, you must specify an IAM role that S3 Files assumes to read from and write to your S3 bucket. This role allows S3 Files to synchronize changes between your file system and your S3 bucket. When you create a file system using the AWS Console, S3 Files automatically creates this IAM role with the required permissions. If you are using the AWS CLI or S3 API, see IAM role for accessing your bucket from the file system.

For more information about managing permissions for API operations, see How S3 Files works with IAM.

Status of a file system

A file system can have one of the status values described in the following table that you can get using the `get-file-system` command.

File system state	Description
AVAILABLE	The file system is in a healthy state, and is reachable and available for use.
CREATING	S3 Files is in the process of creating the new file system.

File system state	Description
DELETING	S3 Files is deleting the file system in response to a user-initiated delete request.
DELETED	S3 Files has deleted the file system in response to a user-initiated delete request.
ERROR	The file system is in a failed state and is unrecoverable. To access the file system data, restore a backup of this file system to a new file system. Check the StatusMessage field for information about the error.
MISCONFIGURED	A permissions issue prevents S3 Files from synchronizing changes between the file system and its S3 bucket. For more information, see File system status is MISCONFIGURED.

Note

S3 Files returns an error when you attempt to create a file system scoped to a prefix with a large number of objects. This error alerts you that large recursive rename or move operations may impact file system performance and increase S3 request costs, as every file requires separate copy and delete requests to your S3 bucket. If you still want to create a file system scoped to that prefix, you can add the `--AcceptBucketWarning` parameter.

Using the S3 console

This section explains how to use the Amazon S3 console to create a file system for S3 Files.

- Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
- In the navigation bar, verify you are in your desired AWS Region.
- In the left navigation pane, choose **File systems**.
- Select **Create file system**.
- On the create page, choose the S3 bucket or prefix to create your file system from. You can enter the S3 URI directly (for example, `s3://bucket-name/prefix`) or choose **Browse S3** to navigate to and select your bucket or prefix.

- Select a VPC for your file system. S3 Files selects your default VPC automatically. This is the VPC where your compute resources connect to your file system. To use a different VPC, choose one from the dropdown.
- Select **Create** and wait for the status of your file system to become `Available`.

Default settings on AWS Management Console

S3 Files will create your file system with the following configuration:

- **Encryption** — S3 Files sets the encryption configuration from the source S3 bucket and applies it to data at rest in your file system.
- **IAM role** — S3 Files creates a new IAM role that it assumes to manage the data synchronization between your file system and bucket.
- **Mount targets** — S3 Files automatically creates one mount target in every Availability Zone in the VPC you choose.
- **Access point** — S3 Files creates one access point for the file system.

Using the AWS CLI

When you're using the AWS CLI, you create these resources in order. First, you create a file system. Then, you can create mount targets and any additional optional tags for the file system by using corresponding AWS CLI commands.

The following `create-file-system` example command shows how you can use the AWS CLI to create a file system for S3 Files.

```
aws s3files create-file-system --region aws-region --bucket s3-bucket-arn --client-
token idempotency-token --role-arn iam-role
```

Replace the following with your desired values:

- *`aws-region`* : The AWS Region of your bucket. For example, `us-east-1`.
- *`bucket-arn`* : The ARN of your S3 bucket.
- *`idempotency-token`* : An idempotency token. This is optional.
- *`iam-role`* : ARN of the IAM role that S3 Files assumes to read from and write to your S3 bucket. Make sure you have added the right permissions to this IAM role. For more information, see IAM role for accessing your bucket from the file system.

After successfully creating the file system, S3 Files returns the file system description as JSON.

Deleting file systems

When you delete a file system, the file system, its data, and its configuration are permanently removed. Make sure no applications are actively using the file system before deletion to avoid service disruption. Before deletion, you must delete all mount targets and access points associated with the file system first. For more information, see Deleting mount targets and Deleting access points for an S3 file system.

When you delete a file system, S3 Files checks whether all changes in your file system have been synchronized with your linked S3 bucket. If there are changes that have not yet been synchronized, S3 Files returns an error and the deletion does not proceed. This ensures that all your data is safely stored in your S3 bucket before the file system is deleted. If you want to proceed with deletion and accept that any unsynchronized changes will be lost, you can retry the delete request with the 'force delete' option. In the AWS CLI, add the `--ForceDelete` flag to your delete API call. On the AWS Console, choose **Force** button in the error message that appears when you delete a file system while unsynced changes are present.

Using the S3 console

This section explains how to use the Amazon S3 console to delete a file system for S3 Files.

- Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
- In the navigation bar, verify you are in the AWS Region of the file system that you want to delete.
- In the left navigation pane, choose **General purpose buckets**.
- Choose a general purpose bucket your file system is attached to.
- Select the **File systems** tab and select the file system you wish to delete.
- Choose **Delete**.
- In the confirmation window, type `confirm`.

Using the AWS CLI

The following `delete-file-system` example command shows how you can use the AWS CLI to delete a file system for S3 Files.

```
aws s3files delete-file-system --file-system-id file-system-id
```

Creating mount targets

You need a mount target to access your file system from compute resources and you can create a maximum of one mount target per Availability Zone. We recommend creating one mount target per Availability Zone you operate in. When you create a file system using the S3 console, S3 Files automatically creates one mount target in every Availability Zone in your default VPC.

You can create mount targets for the file system in one VPC at a time. If you want to modify the VPC for your mount targets, you need to first delete all the existing mount targets for the file system and then create a mount target in a new VPC. If the VPC has multiple subnets in an Availability Zone, you can create a mount target in only one of those subnets. All EC2 instances in the Availability Zone can share the single mount target.

Using the S3 console

This section explains how to use the Amazon S3 console to create a mount target for S3 Files.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, verify you are in the AWS Region of the file system for which you want to create a mount target.
3. In the left navigation pane, choose **General purpose buckets**.
4. Choose a general purpose bucket your file system is attached to.
5. Select the **File systems** tab and select your desired file system.
6. Select the **Mount targets** tab and select **Create mount targets**.
7. On the Create mount target page, your default VPC will automatically be selected. Choose the Availability Zone and Subnet ID. The VPC, Availability Zone, and Subnet ID cannot be edited after mount target creation.

> **Note**
>
> The IP address type must match the IP type of the subnet. Additionally, the IP address type overrides the IP addressing attribute of your subnet. For example, if the IP address type is IPv4-only and the IPv6 addressing attribute is enabled for your subnet, network interfaces created in the subnet receive an IPv4 address from the range of the subnet. For more information, see Modify the IP addressing attributes of your subnet.

8. If you know the IP address where you want to place the mount target, then enter it in the IP address box that matches the IP address type. If you don't specify a value, S3 Files selects an unused IP address from the specified subnet.
9. Choose your security groups to associate with the mount target. See Security groups in the prerequisites to understand the security group configurations required to start using your file system.
10. Choose **Create mount target**.

Using the AWS CLI

The following `create-mount-target` example command shows how you can use the AWS CLI to create a mount target for S3 Files.

```
aws s3files create-mount-target --region aws-region --file-system-id file-system-id --
subnet-id subnet-id
```

Mount targets can take up to ~5 minutes to create.

Managing mount targets

You can add or remove security groups associated with a mount target. Security groups define inbound and outbound access. When you change security groups associated with a mount target, make sure that you authorize necessary inbound and outbound access. Doing so enables your compute resource to communicate with the file system. See Security groups in the prerequisites to understand the security group configurations required to start using your file system.

Using the S3 console

This section explains how to use the Amazon S3 console to add or remove security groups for a mount target in S3 Files.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, verify you are in the desired AWS Region where your mount target exists.
3. In the left navigation pane, choose **General purpose buckets**.
4. Choose a general purpose bucket your file system is attached to.
5. Select the **File systems** tab and select your desired file system.

6. Select the **Mount targets** tab and select the mount target that you want to edit.
7. Choose **Edit**. You will see details of your mount target.
8. Add or remove security groups from the security group drop down.
9. Choose **Save**.

Using the AWS CLI

The following `update-mount-target` example command shows how you can use the AWS CLI to add or remove security groups for a mount target in S3 Files.

```
aws s3files update-mount-target --region aws-region --mount-target-id mount-target-id
 --security-groups security-group-ids-separated-by-space
```

Deleting mount targets

When you delete a mount target, it breaks any mounts of the file system. This might disrupt compute resources and applications using those mounts. To avoid disruption, stop applications and unmount the file system before you delete the mount target.

You can delete mount targets for a file system by using the AWS Management Console, AWS CLI, or programmatically by using the AWS SDKs.

Using the S3 console

Use the Amazon S3 console to delete a mount target for S3 Files.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, verify you are in the AWS Region of the mount target that you want to delete.
3. In the left navigation pane, choose **General purpose buckets**.
4. Choose a general purpose bucket your file system is attached to.
5. Select the **File systems** tab and select your desired file system.
6. Select the **Mount targets** tab and select the mount target you wish to delete.
7. Choose **Delete**.
8. In the confirmation window, type **`confirm`** and choose **Delete**.

Using the AWS CLI

The following `delete-mount-target` command deletes a mount target for S3 Files using the AWS CLI.

```
aws s3files delete-mount-target --region aws-region --mount-target-id mount-target-id
```

Creating file system policies

You can use file system policies to grant or deny permissions for NFS clients to perform operations such as mounting, writing, and root access on your file systems. A file system either has an empty (default) file system policy or exactly one explicit policy. You can update your file system policy at any time after file system creation using the AWS Management Console, AWS CLI, or AWS SDK.

You can update a file system policy by using the Amazon S3 console, the AWS CLI, programmatically with AWS SDKs, or the S3 Files API directly. These policy changes can take several minutes to take effect. S3 file system policies have a 20,000 character limit. For more information about using an S3 file system policy, supported actions, and supported condition keys, see How S3 Files works with IAM.

Using the S3 console

This section explains how to use the Amazon S3 console to create a file system policy for S3 Files.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, verify you are in the AWS Region where your file system exists.
3. In the left navigation pane, choose **File systems**.
4. Choose your desired file system.
5. Select the **Permissions** tab and select **Edit**.
6. You can use the Policy editor to add your own file system policy.
7. After you complete editing the policy, choose **Save**.

Deleting file system policies

You can delete a file system policy using the Amazon S3 console and the AWS CLI.

Using the S3 console

This section explains how to use the Amazon S3 console to delete a file system policy for S3 Files.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, verify you are in the AWS Region where your file system exists.
3. In the left navigation pane, choose **File systems**.
4. Choose your file system.
5. Select the **Permissions** tab and select **Delete**.
6. In the confirmation window, type **`confirm`** and choose **Delete**.

Using the AWS CLI

The following `delete-file-system-policy` example command shows how you can use the AWS CLI to delete a file system policy for S3 Files.

```
aws s3files delete-file-system-policy --file-system-id file-system-id
```

Creating access points for an S3 file system

Access points are application-specific entry points to a file system that simplify managing data access at scale for shared datasets. You can use access points to enforce user identities and permissions for all file system requests that are made through the access point. Additionally, access points can restrict clients to only access data within a specified root directory and its subdirectories. When you create a file system using the AWS Management Console, S3 Files automatically creates one access point for the file system.

A file system can have a maximum of 25,000 access points. For more information, see Unsupported features, limits, and quotas. You can create access points using the Amazon S3 console, AWS CLI, or AWS SDK.

Access points for an S3 file system cannot be edited after creation. If you want to make updates, you have to delete the existing access point and create a new one.

Using the S3 console

This section explains how to use the Amazon S3 console to create an access point for an S3 file system.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, verify you are in the AWS Region of the file system for which you want to create an access point.
3. In the left navigation pane, choose **File systems**.
4. Choose your desired file system.
5. Select the **Access points** tab and select **Create access point**.
6. On the Create page, enter a **Name** for the access point.
7. (Optional) Specify a root directory path for the access point. Clients using this access point will be limited to this directory and its subdirectories. By default, S3 Files assumes the root directory for the access point to be the root directory of the file system.
8. (Optional) In the **POSIX user** panel, you can specify the full POSIX identity to use to enforce user and group information for all file operations by clients that are using the access point.
   - **User ID** – Enter a numeric POSIX user ID for the user.
   - **Group ID** – Enter a numeric POSIX group ID for the user.
   - **Secondary group IDs** – Enter an optional comma-separated list of secondary group IDs.
9. (Optional) For **Root directory creation permissions**, you can specify the permissions to use when S3 Files creates the root directory path, if specified and the root directory doesn't already exist. If the root directory already exists, including a directory imported from the linked S3 bucket, S3 Files doesn't apply these permissions. To change the directory's owner or permissions, see Setting POSIX metadata on a directory.

   > **Note**
   >
   > If you don't specify any root directory ownership and permissions, and the root directory does not already exist, S3 Files will not create the root directory. Any attempts to mount the file system by using the access point will fail.

   - **Owner user ID** – Enter the numeric POSIX user ID to use as the root directory owner.
   - **Owner group ID** – Enter the numeric POSIX group ID to use as the root directory owner group.
   - **Permissions** – Enter the Unix mode of the directory. A common configuration is 755. Ensure that the execute bit is set for the access point user so that they are able to mount.
10. (Optional) Under **Tags**, you can choose to add tags to your access point.

11. Choose **Create access point**.

Using the AWS CLI

The following `create-access-point` example command shows how you can use the AWS CLI to create an access point for an S3 file system.

```
aws s3files create-access-point --file-system-id file-system-id --root-directory root-directory --posix-user posix-user
```

For example:

```
aws s3files create-access-point --file-system-id fs-abcdef0123456789a --client-token
 010102020-3 \
  --root-directory "Path=/s3files/mobileapp/
east,CreationInfo={OwnerUid=0,OwnerGid=11,Permissions=775}" \
  --posix-user "Uid=22,Gid=4" \
  --tags Key=Name,Value=east-users
```

> **Note**
>
> If multiple requests to create access points on the same file system are sent in quick succession, and the file system is nearing the access points limit, you may experience a throttling response for these requests. This is to ensure that the file system does not exceed the access point quota.

Deleting access points for an S3 file system

When deleting an access point, make sure no applications are actively using the access point before deletion to avoid service disruption. Once deleted, the access point and its configuration are permanently removed.

Using the S3 console

This section explains how to use the Amazon S3 console to delete an access point for S3 Files.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation bar, verify you are in the AWS Region of the file system which has the access point that you want to delete.
3. In the left navigation pane, choose **General purpose buckets**.
4. Choose a general purpose bucket your file system is attached to.
5. Select the **File systems** tab and select the file system you wish to use.
6. Select the **Access points** tab and select the access point you wish to delete.
7. Choose **Delete**.
8. In the confirmation window, type **`confirm`** and choose **Delete**.

Using the AWS CLI

The following `delete-access-point` example command shows how you can use the AWS CLI to delete an access point for S3 Files.

```
aws s3files delete-access-point --access-point-id access-point-id
```

Tagging S3 Files resources

To help you manage your S3 Files resources, you can assign your own metadata to each resource in the form of tags. With tags, you can categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This categorization is useful when you have many resources of the same type as you can quickly identify a specific resource based on the tags that you've assigned to it. You can tag S3 file system and access point resources that already exist in your account. This topic describes tags and shows you how to create them.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- The allowed characters are: letters, numbers, and spaces representable in UTF-8, and the following characters: `+ - = . _ : / @`.

- Tag keys and values are case-sensitive.
- The `aws:` prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the `aws:` prefix do not count against your tags per resource limit.

You can't update or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete file systems that you tagged with a tag key called `DeleteMe`, you must use the `DeleteFileSystem` action with the resource identifiers of the file system, such as the file system ID.

When you tag public or shared resources, the tags that you assign are available only to your AWS account. No other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

Using the S3 console

You can use the S3 Files console to manage tags on your resources.

- Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
- In the navigation bar, verify you are in your desired AWS Region.
- In the left navigation pane, choose **File systems**.
- You can specify tags for a resource when you create the resource, such as an S3 file system or an access point. Or, you can add, modify, or delete tags after creation by going to the properties of the resource.

Using the AWS CLI

If you're using the S3 Files API, the AWS CLI, or an AWS SDK, you can use the `TagResource` S3 Files API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created, such as when you create a file system.

The AWS CLI commands for managing tags, and the equivalent S3 Files API actions, are listed in the following table.

CLI command	Description	Equivalent API operation
`tag-resource`	Add new tags or update existing tags	`TagResource`
`list-tags-for-resource`	Retrieve existing tags	`ListTagsForResource`
`untag-resource`	Delete existing tags	`UntagResource`

Understanding how synchronization works

S3 Files keeps your file system and the linked S3 bucket synchronized automatically. The data you actively use is copied to the file system, so you can read and write files using standard Linux file operations at low latency. S3 Files requires S3 Versioning to be enabled on the linked S3 bucket. When you edit files on the file system, S3 Files copies your changes back to the S3 bucket as new versions of the corresponding objects, making sure the old versions are preserved. When other applications add, modify, or delete objects in your S3 bucket, S3 Files automatically reflects those changes in your file system. When a conflict occurs due to concurrent changes to the same data in both the file system and the S3 bucket, S3 Files treats the S3 bucket as the source of truth in case of conflicts.

To optimize storage costs, S3 Files removes data you have not used recently from the file system. Your data remains durably stored in the linked S3 bucket and is fetched back onto the file system the next time you access it.

S3 bucket is accessible through the file system

After you create an S3 file system, you can mount your S3 buckets on compute resources and start accessing your S3 bucket data right away. By default, when you first access a directory by listing its contents or opening a file within it, S3 Files imports the metadata for all files in that directory, along with the data for files smaller than the import size threshold (default 128 KiB) from the S3 bucket. The first access to a directory might have higher latency, but subsequent reads and writes are significantly faster. By importing metadata upfront, S3 Files enables you to browse directory contents, view file sizes, and check permissions at low latency.

For example, suppose your S3 bucket contains a prefix `data/images/` with 1,000 objects. The first time you run `ls /mnt/s3files/data/images/`, S3 Files imports metadata for all 1,000 files

and asynchronously copies data for files below the import size threshold onto the file system. This initial listing may take several seconds, but subsequent commands such as `ls -la`, `stat`, or `cat` on individual files in that directory return at low latency.

For files larger than the import size threshold, S3 Files imports only metadata, while data is not copied to the file system and is instead read directly from the S3 bucket when you access it. You can adjust this threshold to better match your workload. For example, you can increase it to import more data up front for workloads that repeatedly access the same files and benefit from low-latency reads. For workloads that stream data sequentially, a lower threshold can be more cost effective, as the latency benefit of importing data up front is less meaningful when data is read sequentially in large chunks rather than in small, random reads. For more information, see Customizing synchronization for S3 Files.

Changes in your file system automatically reflect in your S3 bucket

When you create, modify, or delete files in the file system, S3 Files automatically copies those changes to your S3 bucket. New files become new S3 objects, changes to existing files become new object versions, and deleted files become S3 delete markers.

POSIX permissions that you set on files and directories through the file system, such as owner (UID), group (GID), and permission bits, are stored as user-defined S3 object metadata on the corresponding S3 objects. When you change permissions using `chmod`, `chown`, or `chgrp`, S3 Files exports those changes to your S3 bucket along with any data changes. When S3 Files imports objects from your S3 bucket, it reads this metadata and applies the corresponding POSIX permissions on the file system. Objects that do not have POSIX permission metadata are assigned default permissions.

When a file is modified on the file system, S3 Files waits for a period of write inactivity (60 seconds) before exporting those changes back to your S3 bucket. Rapid successive writes to the same file are captured in a single S3 PUT request rather than generating multiple object versions for each individual change. This reduces both your S3 request costs and storage costs. You can use this 60-second inactivity window as an export trigger. For example, if your application appends data to a file every 30 seconds for a total of 5 minutes, S3 Files starts the export process at minute 6. If you make additional changes, the process repeats after each 60-second period of no write activity.

Changes in your S3 bucket automatically appear in your file system

S3 Files monitors changes in your S3 bucket using S3 Event Notifications. When another application working with the S3 API adds, modifies, or deletes objects in your S3 bucket, S3 Files

automatically reflects those changes in the file system for files whose data is currently stored in the file system's high performance storage. Files whose data has been expired from the file system are not updated until the next time you access them, at which point S3 Files retrieves the latest version from the S3 bucket.

Understanding the impact of rename and move operations

Amazon S3 uses a flat storage structure where objects are identified by their key names. While S3 Files lets you organize your data in directories, S3 has no native concept of directories. What appears as a directory in your file system is a common prefix shared by the keys of the objects within the S3 bucket. Additionally, S3 objects are immutable and do not support atomic renames. As a result, when you rename or move a file, S3 Files must write the data to a new object with the updated key and delete the original. When you rename or move a directory, S3 Files must repeat this process for every object that shares that prefix. Therefore, when you rename or move a directory containing tens of millions of files, your S3 request costs and the synchronization time increase significantly.

S3 Files returns an error when you attempt to create a file system scoped to a prefix with a large number of objects such that a rename can take up to 4 hours (approximately up to 12 million objects). This error alerts you that large recursive rename or move operations may impact file system performance, as every file requires separate write and delete requests to your S3 bucket. If you still want to create a file system scoped to that prefix, you can add the `--AcceptBucketWarning` parameter.

Since S3 Files renames objects individually on the S3 bucket, both directories will be visible on the S3 bucket until the rename is fully completed. Objects written after the directory was renamed but before that rename is fully synchronized will not be moved. To simplify data reorganization work, we recommend you do not create new objects through the S3 bucket while renaming a matching directory.

For example, if you run `mv /mnt/s3files/projects/alpha /mnt/s3files/projects/beta`, the rename completes instantly on the file system. On the S3 bucket, S3 Files begins copying and deleting each object to its new key within the S3 bucket (replacing the `projects/alpha/` prefix with `projects/beta/`) and deleting the original. During this process, the S3 bucket temporarily contains objects under both `projects/alpha/` and `projects/beta/`. Once all objects have been moved, only `projects/beta/` remains.

Unused data is expired from the file system to optimize storage

S3 Files optimizes storage costs by automatically removing file data that has not been read recently from the file system. Your data remains safely stored in your S3 bucket. S3 Files only removes the copy from the file system. File metadata, such as names, sizes, and permissions, is never removed from the file system so you can continue browsing your file system at low latency.

If a file in your file system has not been read for 30 days (configurable) and its changes have already been synchronized to the S3 bucket, S3 Files removes the file data from the file system. The next time you read that file, S3 Files retrieves the latest version of the corresponding object from the S3 bucket and copies it back onto the file system.

For example, suppose you process a dataset in `/mnt/s3files/data/batch-jan.parquet` in January and do not access it again. After 30 days, S3 Files removes the file data from the file system. The file still appears in directory listings with its correct size and permissions, but the data is no longer on the file system. When you read the file again in April, S3 Files retrieves it from the S3 bucket and copies it back onto the file system. The first read may have higher latency, but subsequent reads are fast.

S3 bucket is the source of truth in case of conflicts

A conflict occurs when the same file has been modified through the file system and the corresponding S3 object has also changed before S3 Files has synchronized the file system changes back to the S3 bucket. For example, you might edit a file through your mounted file system while another application uploads a new version of the corresponding object, or deletes it, directly in the linked S3 bucket.

S3 Files detects conflicts when it attempts to synchronize your file system changes back to the S3 bucket, or when it receives an S3 event notification indicating that the object has changed. Your S3 bucket serves as the long-term store for your data, so S3 Files considers the S3 bucket as the source of truth when a conflict occurs. This provides predictable consistency, ensuring that the version in your S3 bucket always takes precedence. In case of a conflict, S3 Files moves the conflicting file from its current location in your file system to a lost and found directory and imports the latest version from the linked S3 bucket into the file system.

For example, suppose you edit `/mnt/s3files/report.csv` through the file system. Before S3 Files synchronizes your changes back to the S3 bucket, another application uploads a new version of `report.csv` directly to the S3 bucket. When S3 Files detects the conflict, it moves your

version of `report.csv` to the lost and found directory and replaces it with the version from the S3 bucket.

The lost and found directory is located in your file system's root directory under the name `.s3files-lost+found-`*`file-system-id`*. If you mount your file system through an access point that specifies a root directory, the lost and found directory is not visible from that mount because it is located above the access point's root directory. To access the lost and found directory, mount the file system without an access point or use an access point without a root directory restriction so that you can access the full file system's scope via the access point.

When S3 Files moves a file to the lost and found directory, it prepends the file name with an identifier to distinguish multiple versions of the same file that may be moved over time. Files in the lost and found directory are not copied to your S3 bucket. You can delete files and copy files from this directory, but you cannot move or rename files within it or delete the directory itself. If you want to keep your file system changes instead of the latest version in the S3 bucket, copy the file from the lost and found directory back to its original path. You can retrieve the file's original path from the extended attributes of the file in the lost and found directory. S3 Files will then copy it to your S3 bucket as a new version of the object. For more information, see Troubleshooting S3 Files.

> **Note**
>
> Conflicting files that S3 Files moves to the lost and found directory remain there indefinitely and count toward your file system storage costs. You should delete files from the lost and found directory to free up storage when they are no longer needed.

The default synchronization settings will work for most workloads for low-latency, file-based access to S3 data. For more details about how to configure these parameters, see Customizing synchronization for S3 Files.

Topics

- Customizing synchronization for S3 Files

Customizing synchronization for S3 Files

S3 Files lets you control how data flows between your file system and linked S3 bucket through a synchronization configuration. The default settings balance latency and cost for most workloads,

but you can tune them to match your access patterns. Importing more data up front reduces read latency at the cost of higher storage and write charges. Importing less data keeps storage costs low but means more reads are served from S3 with higher latency. Each configuration has two components: import data rules, which control what data is copied onto the file system and when, and expiration data rules, which control how long unused data stays on the file system. You can update these rules using the AWS Management Console or the PutSynchronizationConfiguration API.

Import data rules

Import data rules control how data is copied from your bucket to the file system. You can have a maximum of 10 import data rules per file system. Each import data rule has the following parameters:

prefix – The S3 prefix that the rule applies to. Specify an empty string ("") for the entire bucket (file system scope) or a specific prefix (for example, "data/ml/") within the file system. The prefix must end with a forward slash (/), unless specifying the entire bucket with "". You must include exactly one import rule for the root directory. Default: "" (entire bucket or file system scope).

trigger – When to import data: ON_DIRECTORY_FIRST_ACCESS or ON_FILE_ACCESS. Default: ON_DIRECTORY_FIRST_ACCESS.

- **ON_DIRECTORY_FIRST_ACCESS** – File data is imported when you first access a directory. For example, when you first access a directory by listing its contents or opening a file within it, data is imported for all immediate children files in that directory smaller than the sizeLessThan threshold. This option is useful for workloads that require low latency when first accessing files.
- **ON_FILE_ACCESS** – File data is imported only when a file is read for the first time. This option minimizes the data imported at the cost of higher latency on first read.

sizeLessThan – Maximum file size (in bytes) to automatically import. While S3 Files imports metadata for all files, it only imports data for files smaller than this threshold. Minimum: 0 bytes (no data imported, metadata will still be imported). Maximum: 52,673,613,135,872 bytes (48 TiB). Default: 131,072 bytes (128 KiB).

> **Note**
>
> Each imported file is metered as a write. A higher sizeLessThan makes more and larger files eligible for import, which increases your write charges. This effect is largest with

ON_DIRECTORY_FIRST_ACCESS, where a single directory traversal imports every eligible file. For more information about metering and pricing, see How S3 Files is metered.

Prefix matching behavior

When multiple import data rules match a file, S3 Files applies the rule with the most specific prefix. For example, assume you have three rules:

- Rule 1: prefix = "" (entire bucket), sizeLessThan = 64 KiB, trigger = ON_FILE_ACCESS
- Rule 2: prefix = "hot/", sizeLessThan = 1 MiB, trigger = ON_DIRECTORY_FIRST_ACCESS
- Rule 3: prefix = "hot/largeData/", sizeLessThan = 256 KiB, trigger = ON_DIRECTORY_FIRST_ACCESS

For a file at hot/largeData/data.txt, S3 Files applies Rule 3. For a file at hot/data.txt, S3 Files applies Rule 2. For a file at cold/data.txt, S3 Files applies Rule 1 because there is no specific rule for the cold/ prefix.

Expiration data rules

Expiration data rules control when unused data is removed from the file system to optimize storage costs. S3 Files removes data after it has not been read for a specified duration and its changes have already been synchronized to the S3 bucket. Whenever a file is read, its expiration timer resets, extending the time that data remains in the file system. You can specify the following parameter in expiration data rules:

daysAfterLastAccess – Number of days after last read when data is removed from the file system. Minimum: 1 day. Maximum: 365 days. Default: 30 days.

If you have long-running workloads that frequently access the same data, consider longer expiration periods (30–90 days). For temporary data, consider shorter periods (1–7 days).

Example configurations

General purpose file share (default configuration) – A team of developers and data scientists mounts an S3 file system to share code, configuration files, and small datasets. Most files are under 128 KiB and are read repeatedly throughout the day. The default configuration works well for this workload: ON_DIRECTORY_FIRST_ACCESS imports metadata and small file data when any

file in a directory is first accessed, which works well when files in the same directory are likely to be accessed together, such as source files in a project or configuration files in a deployment. Subsequent access by any user is fast. When a user opens a large file such as a log archive, S3 Files automatically streams it directly from S3 for high throughput. The 30-day expiration window keeps actively used files on the file system without manual cleanup.

ML training with repeated reads – A training job reads thousands of small files (<10 MiB) repeatedly across multiple epochs. To minimize latency, set a high sizeLessThan threshold (for example, 10 MiB) with ON_DIRECTORY_FIRST_ACCESS so that file data is preloaded when the training script first lists each directory. Set a short expiration (for example, 3 days) so that data is removed from the file system promptly after the training job completes.

Agentic workloads with broad file discovery – An AI agent explores a large repository of documents, code, or knowledge base files to answer queries, reading many small files once as it searches for relevant context. Set sizeLessThan to 0 so that no data is imported onto the file system. The agent can browse the full directory tree at low latency to discover files, while each file read is served directly from S3. This keeps costs low for workloads that touch many files unpredictably but rarely revisit the same file, and scales naturally as you add more agents reading in parallel.

Hot and cold prefixes – A file system contains both frequently accessed configuration files under `config/` and infrequently accessed archive data under `archive/`. Create two import rules: one for `config/` with a high sizeLessThan and ON_DIRECTORY_FIRST_ACCESS, and one for `archive/` with sizeLessThan set to 0 and ON_FILE_ACCESS. This keeps configuration files on the file system for fast access while avoiding storage costs for archive data that is rarely read.

Monitoring and auditing S3 Files

S3 Files integrates with the following AWS services to help you monitor your file systems:

Amazon CloudWatch

By default, S3 Files metric data is automatically sent to CloudWatch at 1-minute periods, unless noted differently for some individual metrics. You can also watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy.

For more information, see Monitoring S3 Files with Amazon CloudWatch.

CloudTrail

CloudTrail captures API calls and related events made by or on behalf of your AWS account and delivers log files to an Amazon S3 bucket that you specify. S3 Files logs management events including creating file systems, creating mount targets, and mounting file systems to compute instances. S3 Files does not log data events, such as file read and write operations.

For more information, see Logging with CloudTrail for S3 Files.

Topics

- Monitoring S3 Files with Amazon CloudWatch
- Logging with CloudTrail for S3 Files

Monitoring S3 Files with Amazon CloudWatch

You can monitor S3 Files file systems using Amazon CloudWatch, which collects and processes raw data from Amazon S3 Files into readable metrics. These metrics are retained for 15 months, so you can access historical information and gain a better perspective on how your file systems are performing.

S3 Files metric data is automatically sent to CloudWatch. Most metrics are sent at 1-minute intervals, while storage metrics are sent every 15 minutes. You can create CloudWatch alarms that send notifications when a metric exceeds a threshold you specify. You can also use CloudWatch dashboards, which are customizable home pages in the CloudWatch Console that you can use to monitor your resources in a single view. For more information, see Creating a customized CloudWatch dashboard.

S3 Files CloudWatch metrics

S3 Files metrics use the `AWS/S3/Files` namespace. All metrics are reported for a single dimension `FileSystemId`. The `AWS/S3/Files` namespace includes the following metrics:

Metric	Description	Units and valid statistics
StorageBytes	The total size of the file system in bytes, which includes data and metadata. This metric is emitted to CloudWatch every 15 minutes.	Units: Bytes. Minimum, Maximum, Average
Inodes	The total number of inodes (such as files, directories, symlinks) in an S3 Files file system. This metric is emitted to CloudWatch every 15 minutes.	Units: Count. Sum
PendingExports	The total number of files and directories pending export to the S3 bucket.	Units: Count. Sum
ImportFailures	The total number of objects that failed to import to the file system after retries (for example, incorrect IAM permissions).	Units: Count. Sum
ExportFailures	Total number of files and directories that failed export and will not be retried. This metric helps you identify terminal export failures so you can troubleshoot and take action (for example, update IAM permissions).	Units: Count. Sum
ImportAge	The age of in-progress changes that the file system imports from the linked S3 bucket. The age is measured from when each change occurred in the bucket. Use this metric to monitor whether imports are up to date. A sustained increase means imports are falling behind changes in the bucket.	Units: Seconds
ExportAge	The age of in-progress changes that the file system exports to the linked S3 bucket. The age is measured from when each change occurred in the file system. Use this metric to monitor whether exports are up to date. A sustained increase	Units: Seconds

Metric	Description	Units and valid statistics
	means exports are falling behind changes in the file system.	
`DataReadBytes`	The number of bytes read from the file system. `SampleCount` gives the number of data read operations. You can calculate data read throughput by viewing this metric per unit time.	Units: Bytes (Minimum, Maximum, Average, Sum), Count (SampleCount)
`DataWriteBytes`	The number of bytes written to the file system. `SampleCount` gives the number of data write operations. You can calculate data write throughput by viewing this metric per unit time.	Units: Bytes (Minimum, Maximum, Average, Sum), Count (SampleCount)
`MetadataReadBytes`	The number of metadata bytes read from the file system. `SampleCount` gives the number of metadata read operations.	Units: Bytes (Minimum, Maximum, Average, Sum), Count (SampleCount)
`MetadataWriteBytes`	The number of metadata bytes written to the file system. `SampleCount` gives the number of metadata write operations.	Units: Bytes (Minimum, Maximum, Average, Sum), Count (SampleCount)
`LostAndFoundFiles`	Total number of files in the lost and found directory. The lost and found directory is located in your file system's root directory under the name `.s3files-lost+found-` *`file-system-id`* . Files in the lost and found directory are not copied to your S3 bucket. When a conflict occurs due to concurrent changes to the same data in both the file system and the S3 bucket, S3 Files treats the S3 bucket as the source of truth and moves the conflicting file to a lost and found directory.	Units: Count. Sum

Metric	Description	Units and valid statistics
`ClientConnections`	The number of active client connections to a file system.	Units: Count. Sum

Client connectivity metrics

S3 Files can optimize read performance by allowing clients to read file data directly from the linked S3 bucket. To support this, the S3 Files client emits connectivity metrics that monitor whether the client can establish the necessary connections.

These metrics are emitted by the S3 Files client (amazon-efs-utils) and are published to the `efs-utils/S3Files` CloudWatch namespace. Metrics emission is enabled by default as part of the S3 Files experience.

Metric	Description	Units and valid statistics
`NFSConnectionAccessible`	Indicates whether the client can connect to the file system through the NFS mount. A value of 1 means the connection is accessible. A value of 0 means the connection is not accessible.	Units: None. Minimum, Maximum, Average
`S3BucketAccessible`	Indicates whether the client has the required permissions to read data from the linked S3 bucket. A value of 1 means the client has the necessary permissions. A value of 0 means the client does not have the necessary permissions.	Units: None. Minimum, Maximum, Average
`S3BucketReachable`	Indicates whether the linked S3 bucket and prefix exist and are reachable from the client. A value of 1 means the bucket and prefix are reachable . A value of 0 means the bucket or prefix is not reachable.	Units: None. Minimum, Maximum, Average

Accessing CloudWatch metrics

You can view S3 Files metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

To view metrics using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, then choose **All metrics**.
3. Choose the **S3Files** namespace.
4. Choose **File System Metrics**.
5. Select the metrics you want to view.
6. Choose the **Graphed metrics** tab to configure the graph display.

To view metrics using the AWS CLI

Use the `get-metric-statistics` command. For example, to view `DataReadBytes`:

```
aws cloudwatch get-metric-statistics \
  --namespace AWS/S3/Files \
  --metric-name DataReadBytes \
  --dimensions Name=FileSystemId,Value=file-system-id \
  --start-time 2025-01-20T00:00:00Z \
  --end-time 2025-01-20T23:59:59Z \
  --period 3600 \
  --statistics Sum
```

Logging with CloudTrail for S3 Files

Amazon S3 Files is integrated with CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in S3 Files. CloudTrail captures all API calls for S3 Files as events, including calls from the S3 Files console and code calls to the S3 Files API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for S3 Files. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to S3 Files, the IP address from which the request was made, who made the request, when it was made, and additional details.

S3 Files information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon S3 Files, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail Event history in the *CloudTrail User Guide*.

For an ongoing record of events in your AWS account, including events for S3 Files, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs.

For more information, see the following topics in the *CloudTrail User Guide*:

- Creating a trail for your AWS account
- AWS service integrations with CloudTrail logs
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

All S3 Files APIs are logged by CloudTrail. For example, calls to the `CreateFileSystem`, `CreateMountTarget` and `TagResource` operations generate entries in the CloudTrail log files. S3 Files also generates CloudTrail logs when you mount your file system on a compute resource.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see CloudTrail userIdentity element in the *CloudTrail User Guide*.

S3 Files does not log data events. Data events include file read and write operations performed on the file system.

Understanding S3 Files log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

Example: CreateFileSystem

The following example shows a CloudTrail log entry that demonstrates the `CreateFileSystem` action:

```
{
    "eventVersion": "1.11",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "111122223333",
        "arn": "arn:aws:sts::111122223333:assumed-role/myRole/i-0123456789abcdef0",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "111122223333",
                "arn": "arn:aws:iam::111122223333:role/myRole",
                "accountId": "111122223333",
                "userName": "myRole"
            },
            "attributes": {
                "creationDate": "2026-03-20T12:58:28Z",
                "mfaAuthenticated": "false"
            },
            "ec2RoleDelivery": "2.0"
        }
    },
    "eventTime": "2026-03-20T17:43:19Z",
    "eventSource": "s3files.amazonaws.com",
    "eventName": "CreateFileSystem",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "aws-cli/2.0",
    "requestParameters": {
```

```
        "bucket": "arn:aws:s3:::amzn-s3-demo-bucket",
        "prefix": "images/",
        "clientToken": "myClientToken",
        "roleArn": "arn:aws:iam::111122223333:role/myS3FilesRole"
    },
    "responseElements": {
        "creationTime": "Mar 20, 2026, 5:43:19 PM",
        "fileSystemArn": "arn:aws:s3files:us-west-2:111122223333:file-system/fs-
abcd123456789ef0",
        "fileSystemId": "fs-abcd123456789ef0",
        "bucket": "arn:aws:s3:::amzn-s3-demo-bucket",
        "prefix": "images/",
        "clientToken": "myClientToken",
        "status": "creating",
        "roleArn": "arn:aws:iam::111122223333:role/myS3FilesRole",
        "ownerId": "111122223333",
        "tags": []
    },
    "requestID": "dEXAMPLE-feb4-11e6-85f0-736EXAMPLE75",
    "eventID": "eEXAMPLE-2d32-4619-bd00-657EXAMPLEe4",
    "readOnly": false,
    "resources": [
        {
            "accountId": "111122223333",
            "type": "AWS::S3Files::FileSystem",
            "ARN": "arn:aws:s3files:us-west-2:111122223333:file-system/fs-
abcd123456789ef0"
        }
    ],
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management",
    "tlsDetails": {
        "tlsVersion": "TLSv1.3",
        "cipherSuite": "TLS_AES_128_GCM_SHA256",
        "clientProvidedHostHeader": "s3files.us-west-2.api.aws"
    }
}
```

Example: CreateMountTarget

The following example shows a CloudTrail log entry for the `CreateMountTarget` action:

```
{
    "eventVersion": "1.11",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "111122223333",
        "arn": "arn:aws:sts::111122223333:assumed-role/myRole/i-0123456789abcdef0",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "111122223333",
                "arn": "arn:aws:iam::111122223333:role/myRole",
                "accountId": "111122223333",
                "userName": "myRole"
            },
            "attributes": {
                "creationDate": "2026-03-20T13:09:56Z",
                "mfaAuthenticated": "false"
            },
            "ec2RoleDelivery": "2.0"
        }
    },
    "eventTime": "2026-03-20T18:05:14Z",
    "eventSource": "s3files.amazonaws.com",
    "eventName": "CreateMountTarget",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "aws-cli/2.0",
    "requestParameters": {

```

```
}
```

Performance specifications

S3 Files automatically scales throughput and IOPS to match your workload without requiring you to provision or manage capacity. This page describes the performance characteristics of S3 Files.

Performance summary

Specification	Value
Aggregate read throughput per file system	Up to terabytes per second
Aggregate write throughput per file system	1–5 GiB/s
Maximum read IOPS per S3 bucket with S3 Files	No limit (attach multiple file systems to the same bucket)
Maximum write IOPS per S3 bucket with S3 Files	No limit (attach multiple file systems to the same bucket)
Maximum read IOPS per file system	250,000
Maximum write IOPS per file system	50,000
Maximum per-client read throughput	3 GiB/s

How S3 Files delivers performance

S3 Files serves data from two storage tiers, and automatically routes each operation to the tier best suited for it.

High-performance storage – The low-latency storage layer within your file system where actively used file data and metadata reside. S3 Files automatically manages this storage, copying data onto it when you access files and removing data that has not been read within a configurable expiration window. You pay a storage rate for data residing on the high-performance storage.

Direct from S3 – S3 Files streams file reads directly from your S3 bucket in two cases: when the file's data is not stored in the file system's high-performance storage, and for large reads >= 1 MiB,

even when the data also resides on the file system's high-performance storage. The S3 bucket is optimized for high throughput while the file system's high-performance storage layer is optimized for low-latency access. This tiering approach for streaming data directly from S3 bucket provides high throughput for sequential reads, making it well suited for analytics, media processing, and other streaming workloads. S3 Files asynchronously imports data for small files (< 128 KiB by default) to the file system's high-performance storage for low latency access on subsequent reads.

Since S3 Files automatically applies this two-tier model, you do not have to choose between latency and throughput. Small-file workloads get file system performance. Large-file workloads get S3 throughput. Mixed workloads get both.

Read performance

Read throughput scales with the number of connected compute instances and the degree of parallelism within each instance. The maximum per-client read throughput is 3 GiB/s. S3 Files supports up to terabytes per second of aggregate read throughput and up to 250,000 read IOPS per file system.

Write performance

Writes go to the high-performance storage and are durable immediately. Depending on the region, S3 Files supports 1–5 GiB/s of aggregate write throughput and up to 50,000 write IOPS per file system. Write performance scales elastically with workload activity.

When you modify a file in the file system, S3 Files waits approximately 60 seconds, aggregating any successive changes to the file in that time, before copying to your S3 bucket. This means that rapid successive writes to the same file are captured in a single S3 PUT request rather than generating a new object version for every individual change, reducing your S3 request costs and storage costs. If you continue to modify the file after S3 Files has copied your changes back to the S3 bucket, it will copy subsequent changes as needed.

First access latency

The first time you access a directory, S3 Files imports metadata for all files in that directory and, depending on your import configuration, data for small files. So your initial access takes longer than subsequent operations. Once imported, all subsequent directory listings and file access return at low latency.

Synchronization performance

S3 Files synchronizes changes between your file system and S3 bucket in the background.

Importing changes from S3 – When another application adds or modifies an object in your S3 bucket, S3 Files reflects the change in your file system typically within seconds. S3 Files processes up to 2,400 object changes per second per file system, with import data throughput of up to 700 megabytes per second.

Exporting changes to S3 – When you write a file through the file system, S3 Files batches your changes for approximately 60 seconds to consolidate rapid successive writes into a single S3 object version, reducing your S3 request and storage version costs. After the batching window, S3 Files copies the file to your S3 bucket. S3 Files exports up to 800 files per second per file system, with export data throughput of up to 2,700 megabytes per second.

Operation metric	Value	Unit
Import from S3 bucket IOPS	2,400	objects per second per file system
Import from S3 bucket throughput	700	megabytes per second
Export to S3 bucket IOPS	800	files per second per file system
Export to S3 bucket throughput	2,700	megabytes per second

Amazon S3 uses a flat storage structure where objects are identified by their key names. While S3 Files lets you organize your data in directories, S3 has no native concept of directories. What appears as a directory in your file system is a common prefix shared by the keys of the objects within the S3 bucket. Additionally, S3 objects are immutable and do not support atomic renames. As a result, when you rename or move a file, S3 Files must write the data to a new object with the updated key and delete the original. When you rename or move a directory, S3 Files must repeat this process for every object that shares that prefix. Therefore, when you rename or move a directory containing tens of millions of files, your S3 request costs and the synchronization time increase significantly. A directory rename of 100,000 files takes a few minutes to fully reflect in the S3 bucket, though the rename is instant on the file system. For more information, see Understanding the impact of rename and move operations.

If your workload generates changes faster than the synchronization rate, S3 Files queues the changes and processes them in order. You can monitor the count of pending exports using the `PendingExports` CloudWatch metric. For more information, see Monitoring S3 Files with Amazon CloudWatch.

Monitoring performance

You can monitor your file system's performance using Amazon CloudWatch. S3 Files publishes metrics including `DataReadBytes`, `DataWriteBytes`, `MetadataReadBytes`, and `MetadataWriteBytes`, which you can use to track throughput and IOPS over time. For more information, see Monitoring S3 Files with Amazon CloudWatch.

Security for S3 Files

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

Security of the cloud

AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Amazon S3 Files, see AWS Services in Scope by Compliance Program.

Security in the cloud

Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon S3 Files.

Data Protection

The AWS shared responsibility model applies to data protection in S3 Files. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with S3 Files or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Encryption

S3 Files provides comprehensive encryption capabilities to protect your data both at rest and in transit.

Encryption at rest

Your S3 bucket is encrypted using Amazon S3's encryption mechanisms. For information on encryption of data in S3, see Protecting data with encryption.

S3 Files encrypts data at rest in the S3 file system using server-side encryption. Server-side encryption is the encryption of data at its destination by the application or service that receives it. In S3 file systems, data and metadata are encrypted by default before being written to storage and are automatically decrypted when read. These processes are handled transparently by S3 Files, so you don't need to modify your applications. All data at rest in the file system is encrypted using one of the following methods:

- (Default) Server-side encryption with Amazon S3-managed encryption keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (SSE-KMS)

There are additional charges for using AWS KMS keys. For more information, see AWS KMS key concepts in the *AWS Key Management Service Developer Guide* and AWS KMS pricing.

Server-side encryption with Amazon S3-managed encryption keys (SSE-S3)

This is the default method for encrypting data at rest in your S3 file system. Amazon S3-managed encryption keys are a collection of keys that Amazon S3 owns and manages. S3 Files owns and manages encryption of your data and metadata at rest in your S3 file system when you use an Amazon S3-managed encryption key. For more information about Amazon S3-managed encryption keys, see Protecting data with Amazon S3 managed keys.

Server-side encryption with AWS Key Management Service (SSE-KMS)

While creating your file system, you can choose to configure an AWS Key Management Service (AWS KMS) key that you manage. When you use SSE-KMS encryption with an S3 file system the AWS KMS keys must be in the same Region as the file system.

S3 Files key policies for AWS KMS

Key policies are the primary way to control access to customer managed keys. For more information on key policies, see Key policies in AWS KMS in the *AWS Key Management Service Developer Guide*. The following list describes all the AWS KMS–related permissions that are supported by S3 Files for encrypting file systems at rest:

kms:Encrypt

(Optional) Encrypts plaintext into ciphertext. This permission is included in the default key policy.

kms:Decrypt

(Required) Decrypts ciphertext. Ciphertext is plaintext that has been previously encrypted. This permission is included in the default key policy.

kms:ReEncrypt

(Optional) Encrypts data on the server side with a new customer managed key, without exposing the plaintext of the data on the client side. The data is first decrypted and then re-encrypted. This permission is included in the default key policy.

kms:GenerateDataKeyWithoutPlaintext

(Required) Returns a data encryption key encrypted under a customer managed key. This permission is included in the default key policy under kms:GenerateDataKey*.

kms:CreateGrant

(Required) Adds a grant to a key to specify who can use the key and under what conditions. Grants are alternate permission mechanisms to key policies. For more information on grants, see Grants in AWS KMS in the *AWS Key Management Service Developer Guide*. This permission is included in the default key policy.

kms:DescribeKey

(Required) Provides detailed information about the specified customer managed key. This permission is included in the default key policy.

kms:ListAliases

(Optional) Lists all of the key aliases in the account. When you use the console to create an encrypted file system, this permission populates the Select KMS key list. We recommend using this permission to provide the best user experience. This permission is included in the default key policy.

Key states and their effects

The state of your KMS key directly affects access to your encrypted file system:

Enabled

Normal operation - full read and write access to the file system.

Disabled

File system becomes inaccessible after some time. Can be re-enabled.

Pending deletion

File system becomes inaccessible. Deletion can be canceled during the waiting period. Note that after cancelling key deletion, the key needs to be moved to enabled state.

Deleted

File system permanently inaccessible. This action cannot be reversed.

> **Warning**
>
> If you disable or delete the KMS key used for your file system, or revoke S3 Files access to the key, your file system will become inaccessible. This can result in data loss if you don't have backups. Always ensure you have proper backup procedures in place before making changes to encryption keys.

Encryption in transit

S3 Files requires encryption of data in transit using Transport Layer Security (TLS). When you mount your file system using the mount helper, all data traveling between your client and the file system is encrypted using TLS. The mount helper initializes efs-proxy process to establish a secure TLS connection with your file system. The mount helper also creates a process called amazon-

efs-mount-watchdog that monitors the health of mounts, and is started automatically the first time an S3 file system is mounted. It ensures that each mount's efs-proxy process is running, and stops the process when the file system is unmounted. If for some reason the process is terminated unexpectedly, the watchdog process restarts it.

The following describes how TLS encryption in transit works:

1. A secure TLS connection is established between your client and the file system
2. All NFS traffic is routed through this encrypted connection
3. Data is encrypted before transmission and decrypted upon receipt

Encryption of data in transit changes your NFS client setup. When you inspect your actively mounted file systems, you see one mounted to 127.0.0.1, or localhost, as in the following example.

```
$ mount | column -t
127.0.0.1:/  on  /home/ec2-user/s3files        type  nfs4
 (rw,relatime,vers=4.1,rsize=1048576,wsize=1048576,namlen=255,hard,proto=tcp,port=20127,timeo=6
```

You mount your file system using the mount helper, which always encrypts data in transit using TLS. Therefore, while mounting, your NFS client is reconfigured to mount to a local port.

How S3 Files works with IAM

This page describes how AWS Identity and Access Management (IAM) works with S3 Files and how you can use IAM policies to control access to your file systems.

S3 Files uses IAM for two distinct types of access control:

- **API access** — Controls who can create, manage, and delete S3 Files resources such as file systems, mount targets, and access points. You control this access using identity-based policies attached to IAM users, groups, or roles.
- **Client access** — Controls what clients (your mounted compute resources) can do with the file system once they connect, such as reading, writing, or accessing files as the root user. You control this access using a combination of resource-based policies, identity-based policies, access points, and POSIX permissions.

Using IAM, you can permit clients to perform specific actions on a file system, including read-only, write, and root access. An "allow" permission on an action in either an IAM identity policy or a file

system resource policy allows access for that action. The permission does not need to be granted in both an identity and a resource policy.

Your S3 bucket policies on your linked S3 bucket also govern access from your compute resource and your file system to your S3 bucket. You must also make sure that the bucket policies of your source bucket don't deny access from your compute resource or file system. For more details, see Bucket policies for Amazon S3.

Identity-based policies

Identity-based policies are JSON policies that you attach to IAM users, groups, or roles. You can provide these permissions by writing custom policies or by attaching an AWS managed policy. For more information about available managed policies for both API access and client access, see AWS managed policies for Amazon S3 Files.

S3 Files also optimizes read performance by allowing clients to read file data directly from the source S3 bucket. When you mount an S3 file system on your compute resource, you must add an inline policy to the IAM role of your compute resource which grants permissions to read objects from the specified S3 bucket. The mount helper uses these permissions to read the S3 data. For more details on this policy, see IAM role for attaching your file system to AWS compute resources.

Resource-based policies

A file system policy is an IAM resource-based policy that you attach directly to a file system to control client access. You can use file system policies to grant or deny permissions for clients to perform operations such as mounting, writing, and root access.

A file system either has an empty (default) file system policy or exactly one explicit policy. S3 file system policies have a 20,000 character limit. For information on creating and managing file system policies, see Creating file system policies.

S3 Files actions for clients

You can specify the following actions in a file system policy to control client access:

Action	Description
`s3files:ClientMount`	Provides read-only access to a file system.
`s3files:ClientWrite`	Provides write permissions on a file system.

Action	Description
`s3files:ClientRootAccess`	Provides use of the root user when accessing a file system.

S3 Files condition keys for clients

You can use the following condition keys in the `Condition` element of a file system policy to further refine access control:

Condition key	Description	Operator
`s3files:AccessPointArn`	ARN of the S3 Files access point to which the client is connecting.	String

POSIX permissions

After IAM authorization succeeds, S3 Files enforces standard POSIX (Unix-style) permissions at the file and directory level. POSIX permissions control access based on the user ID (UID), group ID (GID), and permission bits (read, write, execute) associated with each file and directory. Access points can enforce a specific POSIX user identity for all requests, simplifying access management for shared datasets. For more information, see Creating access points for an S3 file system.

Security groups

Security groups act as a network-level firewall that controls traffic between your compute resources and the file system's mount targets. For details on configuring security groups to get started on S3 Files, see Security groups.

AWS managed policies for Amazon S3 Files

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you

reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: AmazonS3FilesFullAccess

You can attach the `AmazonS3FilesFullAccess` policy to your IAM identities. This policy grants full access to Amazon S3 Files, including permissions to create and manage file systems, mount targets, and access points. For more information about this policy, see AmazonS3FilesFullAccess in the AWS Managed Policy Reference.

AWS managed policy: AmazonS3FilesReadOnlyAccess

You can attach the `AmazonS3FilesReadOnlyAccess` policy to your IAM identities. This policy grants read-only access to Amazon S3 Files, including permissions to view file systems, mount targets, access points, and related configurations. For more information about this policy, see AmazonS3FilesReadOnlyAccess in the AWS Managed Policy Reference.

AWS managed policy: AmazonS3FilesClientFullAccess

You can attach the `AmazonS3FilesClientFullAccess` policy to your IAM identities. This policy grants full client access to S3 Files file systems, including the ability to mount, read, write, and access files as the root user. For more information about this policy, see AmazonS3FilesClientFullAccess in the AWS Managed Policy Reference.

AWS managed policy: AmazonS3FilesClientReadWriteAccess

You can attach the `AmazonS3FilesClientReadWriteAccess` policy to your IAM identities. This policy grants read and write client access to S3 Files file systems, including the ability to mount, read, and write. This policy does not grant root access. For more information about this policy, see AmazonS3FilesClientReadWriteAccess in the AWS Managed Policy Reference.

AWS managed policy: AmazonS3FilesClientReadOnlyAccess

You can attach the `AmazonS3FilesClientReadOnlyAccess` policy to your IAM identities. This policy grants read-only client access to S3 Files file systems, including the ability to mount and read from the file system. For more information about this policy, see AmazonS3FilesClientReadOnlyAccess in the AWS Managed Policy Reference.

AWS managed policy: AmazonS3FilesCSIDriverPolicy

You can attach the `AmazonS3FilesCSIDriverPolicy` policy to your IAM identities. This policy grants permissions for the Amazon EFS Container Storage Interface (CSI) driver to manage S3 Files access points on behalf of Amazon EKS clusters. For more information about this policy, see AmazonS3FilesCSIDriverPolicy in the AWS Managed Policy Reference.

AWS managed policy: AmazonElasticFileSystemsUtils

You can attach the `AmazonElasticFileSystemsUtils` policy to your IAM identities. This policy grants permissions for the S3 Files client utilities (amazon-efs-utils) to perform operations such as describing mount targets, publishing CloudWatch metrics and logs, and communicating with AWS Systems Manager. For more information about this policy, see AmazonElasticFileSystemsUtils in the AWS Managed Policy Reference.

Amazon S3 Files updates to AWS managed policies

View details about updates to AWS managed policies for Amazon S3 Files since S3 Files began tracking these changes.

Change	Description	Date
`AmazonElasticFileSystemsUtils` — Updated	Added Amazon CloudWatch PutMetricData permissions to support publishing client connectivity metrics.	April 7, 2026
`AmazonS3FilesCSIDriverPolicy` — Added	New managed policy that grants permissions for the Amazon EFS CSI driver to manage S3 Files access points on behalf of Amazon EKS clusters.	April 7, 2026

Change	Description	Date
`AmazonS3FilesClientReadOnlyAccess` — Added	New managed policy that grants read-only client access to S3 Files file systems.	April 7, 2026
`AmazonS3FilesClientReadWriteAccess` — Added	New managed policy that grants read and write client access to S3 Files file systems.	April 7, 2026
`AmazonS3FilesClientFullAccess` — Added	New managed policy that grants full client access to S3 Files file systems, including root access.	April 7, 2026
`AmazonS3FilesReadOnlyAccess` — Added	New managed policy that grants read-only access to S3 Files resources.	April 7, 2026
`AmazonS3FilesFullAccess` — Added	New managed policy that grants full access to S3 Files resources.	April 7, 2026
S3 Files started tracking changes	Amazon S3 Files started tracking changes for its AWS managed policies.	April 7, 2026

Control client access to an S3 Files file system

This topic describes how to use file system policies, IAM identity policies, and network controls to control which clients can access your S3 Files file system and through which access points.

S3 Files access points

S3 Files access points are application-specific entry points to a file system that simplify managing data access at scale. You can use access points to enforce user identities and permissions for all file system requests made through the access point, and restrict clients to only access data within a specified root directory and its subdirectories.

Access points scope what a client can do on the file system. They do not scope which clients can use them. Any role in your account with `s3files:ClientMount` permission can mount through any access point on the file system unless a file system policy restricts it. To control which clients can use which access point, combine three layers: network controls (prevent the connection), a file system resource policy (explicit deny that survives identity policy changes), and an IAM identity policy (least privilege on the role).

S3 Files evaluates `s3files:ClientMount`, `s3files:ClientWrite`, and `s3files:ClientRootAccess` against the file system policy on every mount. The `s3files:AccessPointArn` condition key is also evaluated on every mount, so you can write a single deny statement that blocks access through any access point except the one you specify. If any required action is denied or not granted, the mount fails before any file operations occur. The following two sections cover the two common requirements: restricting a workload to a specific access point, and denying a workload access to the file system altogether.

Restrict access to a specific access point

This pattern applies when a role (for example, an EC2 instance role or an ECS task role) must mount the file system through one access point only. The condition key is `s3files:AccessPointArn`. The policy requires both an `Allow` for the intended access point and an explicit `Deny` for every other access point. IAM allow grants are additive across identity and resource policies; without an explicit deny, a separate policy can grant access to a different access point.

A role is allowed to mount and write only when the request targets `fsap-ID`, and is explicitly denied on every other access point on this file system. An explicit deny in a resource policy cannot be overridden by identity policies, so this restriction holds even if a broader IAM policy is attached to the role later.

Mount command:

```
sudo mount -t s3files -o accesspoint=fsap-ID fs-ID:/ /mnt/s3files
```

Deny a workload access through any access point

This pattern applies when a role shares an account with an S3 Files file system but must not mount it through any access point or directly. To block all access point usage, apply three layers ordered from strongest to weakest isolation guarantee.

1. Network controls. Remove the security group rule that grants `compute-b-role`'s instances access to the mount target on TCP port 2049. Network controls are the most resilient layer because they prevent the mount attempt before any credential exchange occurs. Even if a misconfigured policy grants mount permissions, the NFS connection cannot reach the mount target.

2. Explicit deny in the file system policy. A deny statement in the file system policy rejects the mount even if the role is granted broader IAM permissions later. A file system resource policy provides a deny that persists even if someone with `iam:PutRolePolicy` modifies the role's identity policies. Only principals with `s3files:PutFileSystemPolicy` can change this layer.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyComputeBOnFileSystem",
      "Effect": "Deny",
      "Principal": { "AWS": "arn:aws:iam::ACCOUNT:role/compute-b-role" },
      "Action": "s3files:Client*",
      "Resource": "*"
    }
  ]
}
```

3. IAM identity policy. Do not grant `s3files:Client*` permissions to the role. This is the final layer and the easiest to misconfigure, since any administrator with `iam:PutRolePolicy` can grant mount permissions to a role.

Without a file system policy, any role can mount through any access point

A file system resource policy provides a deny that cannot be removed by someone who only has permission to modify identity policies. Without a file system policy, any role with `s3files:ClientMount` in its identity policy can mount through any access point on the file system. We recommend that you attach a file system policy to every file system with a deny baseline, then add allow statements per workload.

Best practices for access point isolation

The following table summarizes recommended approaches for common access point isolation goals.

Goal	Recommended approach
Restrict a workload to a single access point	Allow the role on the specific access point ARN, plus an explicit deny on every other access point. See "Restrict access to a specific access point."
Block a role in the same account from mounting the file system	Remove network access to port 2049, deny in file system policy, and do not grant in IAM.
Multiple workloads on the same file system, each scoped to their own access point	Maintain one allow + deny pair per role in the file system policy, each scoped to a different access point ARN.
Cross-account access through an access point	Use the file system policy to grant the cross-account role on the specific access point ARN. Do not rely on identity policies alone.

POSIX permissions in S3 Files

POSIX file systems require ownership and permissions on every file. Amazon S3 stores data as objects with access controlled by IAM policies and bucket policies and does not natively store file ownership or permission attributes. S3 Files bridges this difference by storing POSIX metadata, including the owner, group, and file permissions, as user-defined metadata on each S3 object. When you create or modify a file through S3 Files, the service writes all permission metadata automatically. When an object is written to your S3 bucket outside the file system, for example through the Amazon S3 console, AWS CLI, or AWS SDK, no POSIX metadata exists on that object. S3 Files assigns those objects a default value of `root:root` ownership and `644` permissions, which allow non-root users to read the file but not write to it. If these defaults meet your access requirements, no action is required. If your application requires it, you can override the default permissions on those objects. This tutorial walks through applying custom permissions.

POSIX permissions and direct S3 access

S3 Files applies access controls on two independent paths. POSIX user and group permissions govern the operating system users and processes that access the file-system mount. IAM and bucket policies govern the Amazon S3 API.

POSIX permissions do not restrict access made directly through the Amazon S3 API. Any principal with `s3:GetObject` on the bucket can read object contents directly, regardless of the POSIX permissions stored on the object. Treat IAM and bucket policies as the control for direct S3 access, and grant them following the principle of least privilege.

How S3 Files stores POSIX metadata

S3 Files stores POSIX information as user-defined metadata on each object. The following metadata keys control ownership and permissions:

Metadata key	Description	Example value
`x-amz-meta-file-owner`	POSIX user ID (UID)	`1000`
`x-amz-meta-file-group`	POSIX group ID (GID)	`1000`
`x-amz-meta-file-permissions`	File type and permission bits (octal)	`0100644`

When an object has no POSIX metadata, S3 Files applies the following defaults:

- **Files:** `root:root` ownership with `0644` permissions (`-rw-r--r--`)
- **Directories:** `root:root` ownership with `0755` permissions (`drwxr-xr-x`)

Under these defaults, all users can read files and traverse directories, but only the owner (root) can write. Files are not executable by default.

Setting POSIX metadata on existing objects

Use the following procedure to apply POSIX ownership and permissions to objects that already exist in your bucket.

Step 1: Identify the target user's UID and GID

For this example, the target user is `ec2-user` with UID 1000:

```
$ id ec2-user
```

```
uid=1000(ec2-user) gid=1000(ec2-user) groups=1000(ec2-user)
```

Step 2: Update object metadata using copy-object

The `aws s3api copy-object` command copies the object in place with updated metadata. Replace *BUCKET_NAME* and *OBJECT_KEY* with your values.

The `--metadata-directive REPLACE` option replaces all user-defined metadata on the object. Include `--content-type` to preserve the object's content type, because REPLACE resets it to the default (`binary/octet-stream`). If you use other metadata fields, include them in the `--metadata` parameter.

```
aws s3api copy-object \
    --bucket BUCKET_NAME \
    --key OBJECT_KEY \
    --copy-source BUCKET_NAME/OBJECT_KEY \
    --metadata-directive REPLACE \
    --content-type CONTENT_TYPE \
    --metadata '{"file-owner":"1000", "file-group":"1000", "file-
permissions":"0100644"}'
```

Step 3: Verify metadata was applied

Run the following command to confirm the metadata:

```
aws s3api head-object --bucket BUCKET_NAME --key OBJECT_KEY
```

The response includes your POSIX metadata:

```
{
    "AcceptRanges": "bytes",
    "LastModified": "Mon, 18 May 2026 14:43:00 GMT",
    "ContentLength": 7214,
    "ETag": "\"abc123...\"",
    "ContentType": "image/png",
    "Metadata": {
        "file-owner": "1000",
        "file-group": "1000",
        "file-permissions": "0100644"
    }
}
```

Step 4: Verify permissions on the S3 file system

```
$ ls -ltr /mnt/s3files/
-rw-r--r--. 1 ec2-user ec2-user 7214 May 18 14:43 s3.png
```

The file is now owned by `ec2-user` and no longer requires root to access.

Setting POSIX metadata on a directory

A directory's ownership and permissions come from a single object: the zero-byte directory marker at the prefix key with a trailing slash, for example `data/`. S3 Files reads POSIX metadata from that one marker object to determine the directory's owner, group, and permissions. The objects inside the directory do not affect it. Each child object carries its own metadata and governs only itself.

When a directory's objects were written to your bucket before the file system existed, the directory marker has no POSIX metadata. This also applies when the objects were written through the Amazon S3 console, AWS CLI, or AWS SDK. In that case, S3 Files assigns the directory the default `root:root` ownership with `0755` permissions. With these permissions, all users can read and traverse the directory, but only the owner (root) can create or delete files within it. As a result, a non-root user receives a permission error when writing to the directory.

For directories, set the `file-permissions` value with directory bits, for example `0040755`. For more values, see Permission values reference.

To update the directory's metadata in place, copy the directory marker object onto itself with new metadata. This keeps any content stored in the object.

```
aws s3api copy-object \
    --bucket BUCKET_NAME \
    --key data/ \
    --copy-source BUCKET_NAME/data/ \
    --metadata-directive REPLACE \
    --metadata '{"file-owner":"1001", "file-group":"1001", "file-
permissions":"0040755"}'
```

If the command returns a 404 error, the directory marker object doesn't exist. The directory is implied only by its child keys, so it uses the `root:root` default. Create the marker object with the metadata.

```
aws s3api put-object \
    --bucket BUCKET_NAME \
```

```
    --key data/ \
    --metadata '{"file-owner":"1001", "file-group":"1001", "file-
permissions":"0040755"}'
```

Setting metadata on the directory marker changes only the directory itself. To change a child file's ownership, set metadata on that file object. For instructions, see Setting POSIX metadata on existing objects.

Setting POSIX metadata on new uploads

You can include POSIX metadata when you upload objects to your bucket.

Using aws s3 cp

```
aws s3 cp localfile.txt s3://BUCKET_NAME/localfile.txt \
    --metadata '{"file-owner":"1000", "file-group":"1000", "file-
permissions":"0100644"}'
```

Using aws s3api put-object

```
aws s3api put-object \
    --bucket BUCKET_NAME \
    --key localfile.txt \
    --body localfile.txt \
    --metadata '{"file-owner":"1000", "file-group":"1000", "file-
permissions":"0100644"}'
```

Verify metadata on the uploaded object

```
aws s3api head-object --bucket BUCKET_NAME --key localfile.txt
```

Permission values reference

The following table lists common POSIX permission values and their use cases.

Octal value	File mode	Use case
0100644	-rw-r--r--	Standard file: owner read/write, others read-only
0100664	-rw-rw-r--	Shared file: owner and group read/write, others read-only

Octal value	File mode	Use case
0100755	-rwxr-xr-x	Executable: owner full access, others read and execute
0100666	-rw-rw-rw-	World-writable file: all users can read and write
0040755	drwxr-xr-x	Standard directory: owner full access, others read and traverse

Best practices

Upload files through the S3 file system whenever possible. S3 Files automatically stores the file's ownership and permissions as object metadata, so no additional steps are required. When uploading directly to the S3 bucket, include POSIX metadata in the upload command to ensure the correct ownership and permissions are set from the start.

How S3 Files is metered

S3 Files is a shared file system linked to your S3 bucket, designed to deliver low-latency file access while keeping costs proportional to your active working set. The file system maintains a view of the objects in your bucket and intelligently translates your file system operations into efficient S3 requests on your behalf. As you work with specific files and directories through the file system, associated file metadata and contents are placed onto the file system's high-performance storage, in particular the portions that benefit from low-latency access. Many read operations bypass the file system entirely, with data served directly from your S3 bucket at S3 GET request rates with no S3 file data charges. Your authoritative data always remains in your S3 bucket. When you write data, it is stored on the file system's highly durable high-performance storage and then synced back to your S3 bucket, keeping the file system and your S3 bucket consistent in both directions.

With S3 Files, you pay a storage charge for the fraction of active data on the file system's high-performance storage, and you pay data access charges when reading from and writing to the file system's high-performance storage. This page explains how each dimension is metered so you can understand and optimize your costs. For pricing by AWS Region, see Amazon S3 Pricing.

How file system storage is metered

When you access data, the file system loads portions of file metadata and contents on demand onto the file system's high-performance storage, delivering fast reads without duplicating your

entire dataset. You configure a file size threshold (default 128 KiB) that determines which files are stored on high-performance storage. Files at or below this threshold benefit most from low-latency access. Files that exceed the threshold are streamed directly from your S3 bucket and incur no S3 Files storage charges. Data not accessed within a configurable window (1 – 365 days, default 30 days) automatically expires from high-performance storage. You pay a storage rate for the fraction of active data residing on high-performance storage. Typically, the fraction is small, since large files stream directly from your S3 bucket, stale data expires automatically, and only small, latency-sensitive files are stored on high-performance storage. The minimum billable file size on high-performance storage is 10 KiB.

How data access is metered

You pay data access charges for metadata operations and for reads and writes to the file system's high-performance storage. Large file reads (1 MiB or larger file IO) are always streamed directly from your S3 bucket, even if data resides on the file system's high-performance storage. S3 is optimized for high throughput reads, while high-performance storage is optimized for low-latency small-file access. Direct reads incur S3 GET requests and an S3 Files metadata read (4 KiB) with no file read charges. Background sync operations also incur data access charges and S3 request charges. Importing data onto high-performance storage incurs write charges, and exporting changes back to your S3 bucket incurs read charges.

How data access is metered from the file system

S3 Files meters every file system operation as either a read or a write and applies to a file or metadata. Each operation has a minimum metered size and is then rounded up to the next 1 KiB increment. This means every operation falls into one or two of four categories: a data read, a metadata read, a data write, or a metadata write. For example, reading a file is metered as both a data read and a metadata read, while renaming a file is metered as a metadata read and a metadata write. No single operation is ever metered as more than two categories.

File reads from high-performance storage are metered at the size of the data read, with a minimum of 32 KiB per read operation.

File writes to high-performance storage are metered at the size of the data written, with a minimum of 32 KiB per write operation.

Metadata reads are metered at a 4 KiB minimum size and apply as S3 Files reads. Metadata read operation examples include listing a directory and viewing file attributes.

Metadata writes are metered at a 4 KiB minimum size and apply as S3 Files writes. Metadata write operation examples include creating or deleting files and directories, renaming, changing permissions, and calling `fsync`.

How streaming directly from your S3 bucket is metered

S3 Files streams reads directly from your S3 bucket in two cases: the file's data is not stored on high-performance storage, or the read is 1 MiB or larger, even if the data also resides on high-performance storage. This design reflects the strengths of each storage layer. The S3 bucket is optimized for high throughput, while the file system is optimized for low-latency access.

For small files (less than 128 KiB by default), S3 Files asynchronously imports data onto high-performance storage so that subsequent reads are served at low latency. For direct bucket streams, you pay for the S3 GET requests and an S3 Files metadata read (4 KiB), with no file read charges.

How bucket synchronization is metered

S3 Files automatically keeps your file system and your linked S3 bucket synchronized. Synchronization is metered as file reads, file writes, and S3 request charges. For more information, see Understanding how synchronization works.

Importing data onto the file system: When S3 copies data from your S3 bucket onto high-performance storage based on your settings, the operation is metered as a file system write. Import writes occur when you access a directory for the first time, when you read a file not stored on high-performance storage, and when S3 Files reflects changes made directly to your S3 bucket. The metered size is the amount of data written to high-performance storage and a metadata write.

Exporting changes to your S3 bucket: When S3 Files copies your file system changes back to your S3 bucket, the operation is metered as a file system metadata and a file read. Only data read from high-performance storage counts toward this charge. For example, if you append data to a file, S3 Files uses `UploadPartCopy` to avoid importing the entire object onto high-performance storage before appending. This optimizes your high-performance storage costs.

Rename and move operations: S3 buckets do not natively support directories or renames. What appears as a directory in your S3 file system is a common prefix shared by object keys in the bucket, and S3 objects are immutable. As a result, when you rename or move a file, S3 Files copies the data to a new object with the updated key (metered as an S3 PUT request) and deletes the original. The synchronization is metered as a metadata read and a file read based on the data's location. If the file data is not stored on high-performance storage, only a 4 KiB metadata read applies. For file renames or directory moves, S3 Files repeats this copy-and-delete for every object

under that prefix. For more information, see Understanding the impact of rename and move operations.

File data expiration: File data not accessed within a configurable window of 1 to 365 days (default 30 days) automatically expires from high-performance storage. Expiration incurs no data access or metadata charges.

Metadata updates: Your file system metadata (inodes) reflects the contents of your linked S3 bucket. As your bucket changes, metadata is updated to stay consistent with the current state of your bucket. Metadata for accessed directories never expires. You can use the Inodes CloudWatch metric to monitor your metadata usage. Metadata expiration incurs no charges. POSIX metadata changes such as chown and chmod update the object in your S3 bucket. S3 objects are immutable, so S3 Files writes a new version of the object with the updated metadata, metered as an S3 PUT request and S3 Files export. Each metadata change creates an additional version of the object.

Metering examples

Listing a large directory for the first time

When you first list a directory, S3 Files imports metadata for all files in that directory. Each file's metadata import is metered as a 4 KiB write. Depending on your import configuration (default 128 KiB), S3 Files also prefetches and copies data for small files in that directory onto the file system's high-performance storage to optimize for the lowest latency. Each file's data import is metered as a write at the file's size (32 KiB minimum). You can control which files have their data imported by configuring your import rules. For more information, see Customizing synchronization for S3 Files.

Reading a small file not stored on high-performance storage

S3 Files streams read directly from your S3 bucket to your client and asynchronously imports data to the file system's high-performance storage, so future reads are faster. This is metered as a file system read at the size of the data transferred (32 KiB minimum). The asynchronous import of data into the file system's high-performance storage is metered as a write at the size of the data transferred. A similar process is followed when you read a file whose data has been expired from the file system. When files expire from the high-performance storage, it does not incur any file system operation charges.

Writing to the file system

All file writes are stored on high-performance storage and metered at the size of the data written with a 32 KiB minimum. S3 Files waits for a period of inactive write activity (60 seconds) in order

to aggregate successive changes to the same file before copying to your S3 bucket. Rapid writes are captured in a single S3 PUT rather than generating a new object version for each individual change. This reduces both S3 request costs and file high-performance storage costs. This bucket synchronization is metered as a file system read for data read from high-performance storage, and an S3 PUT request.

S3 Files best practices

This page describes the recommended best practices for working with S3 file systems.

Performance and cost optimization

- **Parallelize your workloads** – S3 Files is designed to support highly parallel workloads. Distributing reads across multiple files and multiple compute instances helps maximize aggregate throughput. You can also create multiple file systems scoped to different specific prefixes within the same bucket (instead of creating one file system over the entire bucket) to scale horizontally and improve aggregate throughput.
- **Scope your file system to the smallest prefix your workload needs to minimize impact of renames** – S3 has no native concept of directories. When you rename or move a directory, S3 Files must write the data to a new object with the updated key and delete the original for every file in that directory. Renaming directories with tens of millions of files can significantly increase S3 request costs and synchronization time. Scope your file system to your active dataset, or structure your data so that directories you expect to rename contain fewer files. For more information, see Understanding the impact of rename and move operations.
- **Use large IO sizes** – S3 Files meters each read and write operation at a minimum of 32 KB. Using larger IO sizes (1 MB or more) amortizes per-operation overhead and is more cost effective than many small reads or writes. When using the mount helper, the default NFS read and write buffer sizes are set to 1 MB for optimal performance.
- **Tune your sizeLessThan value in import configuration to match your file sizes** – By default, S3 Files caches data for files smaller than 128 KB when you first access a directory. Files larger than this threshold are read directly from S3. If your workload performs small, latency-sensitive reads on larger files, increase the sizeLessThan threshold to match the file sizes you need on the file system's high performance storage for low-latency access. However, a higher threshold also increases the amount of data that S3 Files imports onto high-performance storage, which affects your metered usage. For more information, see Customizing synchronization for S3 Files. For S3 Files pricing, see Amazon S3 pricing on the AWS website.

- **Set expiration windows to match your workload lifecycle** – Data that has not been read within the expiration window is automatically removed from the file system. For short-lived workloads such as batch jobs or training runs, use a shorter expiration (1–7 days) to minimize storage costs. For workloads that revisit the same data over weeks, use a longer expiration (30–90 days) to continue benefiting from the low latency. For more information, see Customizing synchronization for S3 Files.
- **Use prefix-scoped rules for mixed workloads** – If your bucket contains both frequently accessed and infrequently accessed data, create separate import rules for each prefix. This lets you import data aggressively for hot prefixes while keeping cold prefixes metadata-only. For more information, see Customizing synchronization for S3 Files.
- **Create a mount target in every Availability Zone** – We recommend creating one mount target in each Availability Zone you operate in so that you can reduce cross-AZ data transfer costs and improve performance. This ensures that your compute resources always have a local network path to the file system, improving both availability and latency. When you create a file system using the AWS Management Console, S3 Files automatically creates one mount target in every Availability Zone in your selected VPC.

Synchronization

- **Understand the S3 Files consistency model** – When a file in the file system is modified at the same time as its corresponding object in the S3 bucket, S3 Files treats the S3 bucket as the source of truth and moves the file to the lost and found directory. To avoid conflicts, designate one path (file system or S3) as the primary writer.
- **Monitor synchronization health** – Use CloudWatch metrics to track the status of synchronization between your file system and S3 bucket. A growing `PendingExports` indicates that your workload is generating changes faster than the synchronization rate, which means synchronization will take longer to complete. A non-zero `ExportFailures` CloudWatch metric indicates files that could not be exported and require action. For more information, see Troubleshooting S3 Files.

Access control

- **Follow the principle of least privilege** – Grant only the minimum permissions required for each IAM role and file system policy. For example, if a compute resource only needs to read data from the file system, attach the `AmazonS3FilesClientReadOnlyAccess` managed policy instead

of `AmazonS3FilesClientFullAccess`. Additionally, consider creating your file system scoped to a specific prefix rather than the entire bucket, so that clients can only access data within that prefix.

- **Do not modify the S3 Files IAM role** – Do not modify or delete the IAM role that S3 Files assumes to synchronize with your S3 bucket. Changing or removing this role can break synchronization between your file system and S3 bucket.
- **Do not modify the S3 Files EventBridge rule** – S3 Files creates an EventBridge rule (prefixed with DO-NOT-DELETE-S3-Files) to detect changes in your S3 bucket. Do not disable, modify, or delete this rule. Removing it prevents S3 Files from detecting new or changed objects in your bucket, causing your file system to become stale.
- **Consider restricting access to logs written by `efs-utils`** – `efs-utils` writes S3 object key names directly in logs which it stores in the directory `/var/log/amazon/efs`. If your S3 key names contain sensitive information, you should restrict access to this directory through POSIX permissions. For example, you could restrict access through the command `sudo chmod 700 /var/log/amazon/efs`.

Monitoring

- **Set alarms on synchronization failures** – Create CloudWatch alarms on `ImportFailures` and `ExportFailures` to be notified when files fail to synchronize. Failed exports may indicate permission issues, encryption key problems, or path length limits. For more information, see Troubleshooting S3 Files.

Migration

To migrate data from on-premises storage to your S3 bucket for the first time, we recommend using AWS DataSync. DataSync automates and accelerates the transfer of large datasets and preserves file metadata and permissions during migration. For more information, see What is AWS DataSync?.

Unsupported features, limits, and quotas

This page describes the limitations and quotas when using S3 Files.

Unsupported S3 features

- **Archival storage classes** – Objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes cannot be accessed through the file system. Similarly, objects in the S3 Intelligent-Tiering Archive Access or Deep Archive Access tiers cannot be accessed through the file system. You must first restore these objects using the S3 API.
- **S3 Access Control Lists (ACLs)** – S3 ACLs are not preserved after changes are made through the file system. We recommend that you keep ACLs disabled and use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Managing access with ACLs.

File system limitations

- **Hard links** – S3 Files does not support hard links. Each file in the file system corresponds to a single S3 object key.
- **Path component size** – S3 Files does not support objects where any single directory or file name in the path exceeds 255 bytes. A path component is a directory or file name derived from an S3 object key. For example, the key `dir1/dir2/file.txt` has three path components: `dir1`, `dir2`, and `file.txt`.
- **Incompatible S3 object key names** – S3 Files does not support accessing S3 key names that do not map to valid POSIX file paths, including empty path components (`foo//bar`), relative path components (`foo/./bar`, `foo/../bar`), and key names containing null bytes.
- **S3 key size limit** – Files or directories whose full path name exceeds the 1,024-byte S3 object key size limit cannot be exported to S3.
- **Symlink targets** – If an S3 object is a symlink, its target must be a valid path that is not empty and does not exceed 4,080 bytes.
- **POSIX permissions metadata size** – Files or directories where the POSIX permission metadata exceeds 2 KB cannot be exported to S3.

Quotas

The following quotas can be increased by contacting AWS Support.

Resource	Default quota
File systems per AWS account	1,000

To request an increase, open the AWS Support Center, choose **Create Case**, then choose **Service Limit Increase**.

The following quotas cannot be changed.

Resource	Quota
Access points per file system	25,000
Connections per file system	25,000
Mount targets per file system per Availability Zone	1
Security groups per mount target	5
Tags per file system	50
VPCs per file system	1

There are also quotas specific to individual file systems.

Resource	Quota
Maximum file size	52,673,613,135,872 bytes (48 TiB)
Maximum directory depth	1,000 levels
Maximum file name length	255 bytes
Maximum symlink target length	4,080 bytes
Maximum S3 object key length	1,024 bytes

Resource	Quota
Maximum open files per client	65,536
Maximum active user accounts per client	65,536
Maximum locks per file	512 across all connected instances
Maximum locks per mount	8,192 across up to 256 file-process pairs
File system policy size limit	20,000 characters

Unsupported NFS features

S3 Files supports NFSv4.1 and NFSv4.2, with the following exceptions:

- pNFS
- Client delegation or callbacks
- Mandatory locking (all locks are advisory)
- Deny share
- Access control lists (ACLs)
- Kerberos-based security
- NFSv4.1 data retention
- SetUID on directories
- Block devices, character devices, attribute directories, and named attributes
- Optional features introduced in NFSv4.2 (such as server-side copy, sparse file operations, space reservation, application I/O advise, application data blocks, labeled NFS, and custom user-defined extended attributes)
- Persistent reply cache
- The `nconnect` mount option

Troubleshooting S3 Files

This page helps you diagnose and resolve common issues with S3 Files.

- Mount command fails
- Permission denied on file operations
- Intelligent read routing is not working
- File system consistently returns NFS server error
- Missing object in S3 bucket after file system write
- S3 object not visible in the file system
- Files appearing in the lost and found directory
- Synchronization falling behind
- File system status is MISCONFIGURED
- Enabling client debug logs
- Error messages

Mount command fails

The `mount -t s3files` command fails with an error.

Common causes and actions:

- **"mount.s3files: command not found"** – The S3 Files client (amazon-efs-utils) is not installed or is below version 3.0.0. Install or upgrade the client. For more information, see Prerequisites for S3 Files.
- **"Failed to resolve file system DNS name"** – There is no mount target in the Availability Zone where your EC2 instance is running. Create a mount target in that Availability Zone, or launch your instance in an Availability Zone that has a mount target. For more information, see Creating mount targets.
- **Connection timed out** – The security group configuration is not allowing NFS traffic. Verify that the mount target's security group allows inbound TCP on port 2049 from your instance's security group, and that your instance's security group allows outbound TCP on port 2049 to the mount target's security group. For more information, see Prerequisites for S3 Files.
- **"Access denied" during mount** – The IAM role attached to your compute resource does not have the required S3 Files permissions. Verify that the role has the

`AmazonS3FilesClientFullAccess` or `AmazonS3FilesClientReadOnlyAccess` managed policy attached, or at minimum the `s3files:ClientMount` permission. For more information, see Prerequisites for S3 Files.

- **botocore not installed** – The mount helper requires botocore to interact with AWS services. Install botocore following the instructions in the amazon-efs-utils README on GitHub.

Permission denied on file operations

You can mount the file system but receive "Permission denied" or "Operation not permitted" errors when reading, writing, or accessing files.

Common causes and actions:

- **Missing write permission** – If you can read but not write, verify that the IAM role attached to your compute resource includes the `s3files:ClientWrite` permission, or attach the `AmazonS3FilesClientReadWriteAccess` or `AmazonS3FilesClientFullAccess` managed policy. For more information, see AWS managed policies for Amazon S3 Files.
- **Missing root access** – If you receive permission errors when accessing files owned by root (UID 0), your IAM role may not have the `s3files:ClientRootAccess` permission. Without this permission, all operations are performed as the NFS anonymous user (typically nfsnobody), which may not have access to the files. Attach the `AmazonS3FilesClientFullAccess` managed policy or add `s3files:ClientRootAccess` to your policy.
- **File system policy denying access** – If you have attached a file system policy, verify that it does not deny the actions your clients need. An "allow" in either the identity-based policy or the file system policy is sufficient for access. For more information, see How S3 Files works with IAM.
- **POSIX permission mismatch** – S3 Files enforces standard POSIX permissions (owner, group, others) on files and directories. If your application runs as a user that does not match the file's owner or group, access may be denied even if IAM permissions are correct. Use an access point to enforce a specific UID/GID for all requests. For more information, see Creating access points for an S3 file system.

Intelligent read routing is not working

S3 Files performs intelligent read routing as it automatically routes read requests to the storage layer best suited for them, while maintaining full file system semantics including consistency, locking, and POSIX permissions. Small, random reads of actively used files are served from the

high-performance storage for low latency. Large sequential reads and reads of data not on the file system are served directly from your S3 bucket for high throughput, with no file system data charge.

Intelligent read routing may not be working if one of the client connectivity metrics (`NFSConnectionAccessible`, `S3BucketAccessible`, and `S3BucketReachable`) shows 0, or if you are not seeing the expected read throughput.

Common causes and actions:

- **Missing S3 inline policy on compute role** – The IAM role attached to your compute resource must include an inline policy granting `s3:GetObject` and `s3:GetObjectVersion` on the linked S3 bucket. Without this policy, the mount helper cannot read directly from S3 and all reads go through the file system. For more information, see Prerequisites for S3 Files.
- **S3 bucket not reachable** – Check the `S3BucketReachable` metric. If it shows 0, verify that your compute resource has network access to S3 (for example, through a VPC endpoint or NAT gateway).
- **File has been modified** – Reads are only served directly from S3 when the file has not been modified through the file system. If you have written to the file and the changes have not yet been synchronized to S3, reads go through the file system until synchronization completes.

File system consistently returns NFS server error

An encrypted file system consistently returns NFS server errors. These errors can occur when S3 Files cannot retrieve your KMS key from AWS KMS for one of the following reasons:

- The key was disabled.
- The key was deleted.
- Permission for S3 Files to use the key was revoked.
- AWS KMS is temporarily unavailable.

Action to take

First, confirm that the AWS KMS key is enabled. You can view your keys in the AWS KMS console. For more information, see Viewing Keys in the *AWS Key Management Service Developer Guide*.

If the key is not enabled, enable it. For more information, see Enabling and Disabling Keys in the *AWS Key Management Service Developer Guide*.

If the key is pending deletion, cancel the deletion and re-enable the key. For more information, see Scheduling and Canceling Key Deletion in the *AWS Key Management Service Developer Guide*.

If the key is enabled and you are still experiencing issues, contact AWS Support.

Missing object in S3 bucket after file system write

You wrote a file through the file system and expected it to appear as an object in your S3 bucket, but the object is not there. S3 Files waits for a period of write inactivity (60 seconds) before exporting changes back to your S3 bucket. If the object still does not appear after this period, the export might have failed. In such a case, you see the `FailedExports` CloudWatch metric increase.

Action to take

Check the file's export status using extended attributes:

```
getfattr -n "user.s3files.status;$(date -u +%s)" missing-file.txt --only-values
```

The timestamp in the attribute name ensures you get the latest status. Example output:

```
S3Key: s3://bucket/prefix/missing-file.txt
ExportError: PathTooLong
```

`ExportError` is not displayed if there is no export failure. `S3Key` is empty if an S3 object was never linked to the file.

The following table lists all possible `ExportError` values:

Error	Cause
`S3AccessDenied`	The IAM role that S3 Files assumes does not have sufficient permissions to write to the S3 bucket. For more information, see Prerequisites for S3 Files.
`InternalError`	There was an internal system error.

Error	Cause
`S3UserMetadataTooLarge`	S3 user metadata size limit exceeded. See Unsupported features, limits, and quotas for information on these limits.
`EncryptionKeyInaccessible`	The encryption key used by the S3 bucket is inaccessible to S3 Files. Grant S3 Files access to your encryption key. For more information, see Encryption.
`RoleAssumptionFailed`	Could not assume the role. Check your trust policies. For more information, see Prerequisites for S3 Files.
`KeyTooLongToBreakCycle`	S3 Files could not resolve a circular dependency (for example, due to renaming two files to each other's names) because the file path exceeds the S3 key length limit. Shorten the directory path to resolve this error.
`PathTooLong`	Your file path exceeds the S3 key length limit. See Unsupported features, limits, and quotas for information on these limits.
`DependencyExportFailed`	A parent or a dependency has a non-retryable export failure. Check the status for the parent or any dependencies using `getfattr`.
`S3ObjectArchived`	S3 object is archived (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive) and cannot be read. Restore the object first using the S3 APIs.

S3 Files automatically retries failed exports. `ExportError` is shown only for non-retryable errors.

S3 object not visible in the file system

An object exists in your S3 bucket but does not appear in the file system. The object key name may not map to a valid POSIX file path. S3 Files does not support accessing S3 key names with empty path components (`foo//bar`), relative path components (`foo/./bar`, `foo/../bar`), key names containing null bytes, or key names where any path component exceeds 255 bytes. Objects with incompatible key names are not imported into the file system.

Files appearing in the lost and found directory

Files have appeared in the `.s3files-lost+found-`*`file-system-id`* directory in your file system's root directory. In this case, you see the `LostAndFoundFiles` CloudWatch metric increase. This occurs when a synchronization conflict arises. A conflict occurs when the same file is modified through the file system and the corresponding S3 object changes before S3 Files synchronizes the file system changes back to S3. S3 Files treats the S3 bucket as the source of truth, moves the conflicting file to the lost and found directory, and imports the latest version from the S3 bucket into the file system.

Identifying files in the lost and found directory

When S3 Files moves a file to the lost and found directory, it prepends the file name with a hexadecimal identifier to distinguish multiple versions of the same file that may be moved over time. File names longer than 100 characters are truncated to make room for this identifier. The file's original directory path is not preserved in the lost and found directory.

Action to take

Get the file's original path and the corresponding S3 object key:

```
getfattr -n "user.s3files.status;$(date -u +%s)" .s3files-lost
+found-fs-12345678/abcdef1234_report.csv --only-values
```

Example output:

```
S3Key: s3://bucket/prefix/report.csv
FilePath: /data/report.csv
```

Field	Description
`S3Key`	Full S3 path of the object that caused the conflict, or empty if the object was deleted in the S3 bucket.
`FilePath`	Relative path of the file before the conflict.

You can then either keep the latest version from your S3 bucket and delete the file from the lost and found directory, or copy the file from the lost and found directory back to its original path to overwrite the S3 version.

> **Note**
>
> Files in the lost and found directory remain there indefinitely and count toward your file system storage costs. Delete files from the lost and found directory when they are no longer needed.

Synchronization falling behind

The `PendingExports` CloudWatch metric is growing, indicating that your workload is generating changes faster than S3 Files can synchronize them to S3.

This means that your workload may be exceeding the synchronization rate. S3 Files exports up to 800 files per second per file system. Consider reducing the rate of file modifications or distributing work across multiple file systems. Monitor the `PendingExports` metric over time. If it stabilizes or decreases, S3 Files is catching up. If it continues to grow, contact AWS Support.

File system status is MISCONFIGURED

If your file system status is MISCONFIGURED, insufficient permissions prevent S3 Files from importing or exporting data between your file system and your S3 bucket. Changes don't synchronize until you correct the configuration.

The common causes are:

- S3 Files can't assume the AWS Identity and Access Management (IAM) role. Make sure that the trust policy of the IAM role allows S3 Files to assume the role. If the role was deleted or renamed, recreate the role or update your file system to use the correct role.
- The IAM role doesn't have permission to access the S3 bucket. Make sure that the IAM role has a policy that grants access to the linked S3 bucket.
- A bucket policy or a service control policy (SCP) denies access. Make sure that your S3 bucket policy and any AWS Organizations SCPs don't deny access to the IAM role of your file system.
- S3 Files doesn't have permission for a specific key or prefix. If some of your data imports and exports successfully, S3 Files can be missing permission for only part of the bucket under the prefix of your file system. Check the IAM role of your file system, the S3 bucket policy, and the Object Ownership settings of the bucket.
- S3 Files can't use the KMS keys that encrypt your objects. If your bucket uses AWS Key Management Service (AWS KMS) encryption, or if some objects use a different encryption key

than the bucket default, make sure that the key policy of each key allows the IAM role of your file system to use the key. For more information, see S3 Files key policies for AWS KMS.

For more information, see IAM role for accessing your bucket from the file system and How S3 Files works with IAM.

After you correct the configuration, S3 Files automatically retries failed imports and exports. When all failed imports and exports complete, the status of your file system changes to AVAILABLE. It can take more than 24 hours for the status to change to AVAILABLE after you correct the configuration.

> **Important**
>
> If your file system has the MISCONFIGURED status for more than 60 days, some data can become permanently out of sync with your S3 bucket. Correct the configuration as soon as possible. If this occurs, contact AWS Support.

Enabling client debug logs

If you are troubleshooting mount, connectivity, or read bypass issues, you can enable debug-level logging on the S3 Files client to capture more detail.

Mount helper and watchdog logs

Edit `/etc/amazon/efs/s3files-utils.conf` and change the logging level from INFO to DEBUG:

```
[DEFAULT]
logging_level = DEBUG
```

Unmount and remount the file system for the change to take effect:

```
sudo umount /mnt/s3files
sudo mount -t s3files file-system-id:/ /mnt/s3files
```

Logs are written to `/var/log/amazon/efs/`. The mount helper log is `mount.log`.

Proxy (efs-proxy) logs

The proxy handles NFS traffic and S3 read bypass. To enable debug logging for the proxy, edit `/etc/amazon/efs/s3files-utils.conf`:

```
[proxy]
proxy_logging_level = DEBUG
```

Unmount and remount for the change to take effect. Proxy logs are written to `/var/log/amazon/efs/`.

TLS tunnel (stunnel) logs

TLS tunnel logs are disabled by default. To enable them, edit `/etc/amazon/efs/s3files-utils.conf` and set the following:

```
[mount]
stunnel_debug_enabled = true
```

To save all stunnel logs for a file system to a single file, also uncomment the `stunnel_logs_file` line:

```
stunnel_logs_file = /var/log/amazon/efs/{fs_id}.stunnel.log
```

Log size limits

Log files are rotated automatically. You can configure the maximum size and number of rotated files in `s3files-utils.conf`:

```
[DEFAULT]
logging_max_bytes = 1048576
logging_file_count = 10
```

The default is 1 MB per log file with 10 rotated files, for a maximum of 10 MB per log type.

Sharing logs with AWS Support

When contacting AWS Support, collect the client logs and configuration into a single archive:

```
sudo tar -czf /tmp/s3files-support-logs.tar.gz \
  /var/log/amazon/efs/ \
```

```
/etc/amazon/efs/s3files-utils.conf
```

Include `/tmp/s3files-support-logs.tar.gz` with your support case.

Error messages

The following table lists error messages you might encounter and the recommended action for each.

Message	Action Required
Access denied: The provided role does not have permission to call `s3:HeadObject` on the provided bucket.	Your file system IAM role doesn't have sufficient permissions to sync to your bucket. Update your IAM policy to include all required S3 Files permissions. For more information, see Prerequisites for S3 Files.
You attempted to create more file systems than are allowed for an account. For more information, see Unsupported features, limits, and quotas.	For information about how to request a limit increase, see Unsupported features, limits, and quotas.

Access control in Amazon S3

In AWS, a resource is an entity that you can work with. In Amazon Simple Storage Service (S3), *buckets* and *objects* are the original Amazon S3 resources. Every S3 customer likely has buckets with objects in them. As new features were added to S3, additional resources were also added, but not every customer uses these feature-specific resources. For more information about Amazon S3 resources, see S3 resources.

By default, all Amazon S3 resources are private. Also by default, the root user of the AWS account that created the resource (resource owner) and IAM users within that account with the necessary permissions can access a resource that they created. The resource owner decides who else can access the resource and the actions that others are allowed to perform on the resource. S3 has various access management tools that you can use to grant others access to your S3 resources.

The following sections provide you with an overview of S3 resources, the S3 access management tools available, and the best use cases for each access management tool. The lists in these sections aim to be comprehensive and include all S3 resources, access management tools, and common access management use cases. At the same time, these sections are designed to be directories that lead you to the technical details you want. If you have a good understanding of some of the following topics, you can skip to the section that applies to you.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

- Identities
- Access management tools
- Actions
- Access management use cases
- Access management troubleshooting

S3 resources

The original Amazon S3 resources are buckets and the objects that they contain. As new features are added to S3, new resources are also added. The following is a complete list of S3 resources and their respective features.

Resource type	Amazon S3 feature	Description
`bucket`	Core features	A bucket is a container for objects. To store an object in S3, create a bucket and then upload one or more objects to the bucket. For more information, see Creating, configuring, and working with Amazon S3 general purpose buckets.
`object`		An object can be a file and any metadata that describes that file. When an object is in the bucket, you can open it, download it, and move it. For more information, see Working with objects in Amazon S3.
`accesspoint`	Access Points	Access Points are named network endpoints that are attached to buckets that you can use to perform Amazon S3 **object** operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions, network controls, and a customized *access point policy* that works in conjunction with the bucket policy that is attached to the underlying bucket. You can configure any access point to accept requests only from a virtual private cloud (VPC) or configure custom block public access settings for each access point. For more information, see Managing access to shared datasets with access points.
`objectlambdaaccesspoint`		An Object Lambda Access Point is an access point for a bucket that is also associated with a Lambda function. With Object Lambda Access Point, you can add your own code to Amazon S3 `GET`, `LIST`, and `HEAD` requests to modify and process data as it's returned to an application.

Resource type	Amazon S3 feature	Description
		For more information, see Creating Object Lambda Access Points.
`multiregionaccesspoint`		Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from Amazon S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, application requests made to a Multi-Region Access Point global endpoint automatically route through the AWS global network to the closest proximity Amazon S3 bucket. For more information, see Managing multi-Region traffic with Multi-Region Access Points.
`job`	S3 Batch Operations	A job is a resource of the S3 Batch Operations feature. You can use S3 Batch Operations to perform large-scale batch operations on lists of Amazon S3 objects that you specify. Amazon S3 tracks the progress of the batch operation job, sends notifications, and stores a detailed completion report of all actions, providing you with a fully managed, auditable, and serverless experience. For more information, see Performing object operations in bulk with Batch Operations.

Resource type	Amazon S3 feature	Description
`storagelensconfiguration`	S3 Storage Lens	An S3 Storage Lens configuration collects organization-wide storage metrics and user data across accounts. S3 Storage Lens provides admins with a single view of object storage usage and activity across hundreds, or even thousands, of accounts in an organization, with details to generate insights at multiple aggregation levels. For more information, see Monitoring your storage activity and usage with Amazon S3 Storage Lens.
`storagelensgroup`		An S3 Storage Lens group aggregates metrics by using custom filters based on object metadata. S3 Storage Lens groups help you investigate characteristics of your data, such as distribution of objects by age, your most common file types, and more. For more information, see Working with S3 Storage Lens groups to filter and aggregate metrics.
`accessgrantsinstance`	S3 Access Grants	An S3 Access Grants instance is a container for the S3 grants that you create. With S3 Access Grants, you can create grants to your Amazon S3 data for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants.

Resource type	Amazon S3 feature	Description
`accessgrantslocation`		An Access Grants Location is a bucket, prefix within a bucket, or an object that you register in your S3 Access Grants instance. You must register locations within the S3 Access Grants instance before you can create a grant to that location. Then, with S3 Access Grants, you can grant access to the bucket, prefix, or object for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants
`accessgrant`		An Access Grant is an individual grant to your Amazon S3 data. With S3 Access Grants, you can create grants to your Amazon S3 data for IAM identities within your account, IAM identities in other accounts (cross-account), and directory identities added to AWS IAM Identity Center from your corporate directory. For more information about S3 Access Grants, see Managing access with S3 Access Grants

Buckets

There are two types of Amazon S3 buckets: *general purpose buckets* and *directory buckets*.

- **General purpose buckets** are the original S3 bucket type and are recommended for most use cases and access patterns. General purpose buckets also allow objects that are stored across all storage classes, except S3 Express One Zone. For more information about S3 storage classes, see Understanding and managing Amazon S3 storage classes.
- **Directory buckets** use the S3 Express One Zone storage class, which is recommended if your application is performance-sensitive and benefits from single-digit millisecond PUT and GET latencies. For more information, see Working with directory buckets, S3 Express One Zone, and Authorizing Regional endpoint API operations with IAM.

Categorizing S3 resources

Amazon S3 provides features to categorize and organize your S3 resources. Categorizing your resources is not only useful for organizing them, but you can also set access management rules based on the resource categories. In particular, prefixes and tagging are two storage organization features that you can use when setting access management permissions.

> **Note**
>
> The following information applies to general purpose buckets. Directory buckets do not support tagging, and they have prefix limitations. For more information, see Authorizing Regional endpoint API operations with IAM.

- **Prefixes** — A prefix in Amazon S3 is a string of characters at the beginning of an object key name that's used to organize the objects that are stored in your S3 buckets. You can use a delimiter character, such as a forward slash (/), to indicate the end of the prefix within the object key name. For example, you might have object key names that start with the `engineering/` prefix or object key names that start with the `marketing/campaigns/` prefix. Using a delimeter at the end of your prefix, such as as a forward slash character `/` emulates folder and file naming conventions. However, in S3, the prefix is part of the object key name. In general purpose S3 buckets, there is no actual folder hierarchy.

  Amazon S3 supports organizing and grouping objects by using their prefixes. You can also manage access to objects by their prefixes. For example, you can limit access to only the objects with names that start with a specific prefix.

  For more information, see Organizing objects using prefixes. S3 Console uses the concept of *folders*, which, in general purpose buckets, are essentially prefixes that are pre-pended to the object key name. For more information, see Organizing objects in the Amazon S3 console by using folders.
- **Tags** — Each tag is a key-value pair that you assign to resources. For example, you can tag some resources with the tag `topicCategory=engineering`. You can use tagging to help with cost allocation, categorizing and organizing, and access control. Bucket tagging is only used for cost allocation. You can tag objects, S3 Storage Lens, jobs, and S3 Access Grants for the purposes of organizing or for access control. In S3 Access Grants, you can also use tagging for cost-allocation. As an example of controlling access to resources by using their tags, you can share only the objects that have a specific tag or a combination of tags.

For more information, see Controlling access to AWS resources by using resource tags in the *IAM User Guide*.

Identities

In Amazon S3, the resource owner is the identity that created the resource, such as a bucket or an object. By default, only the root user of the account that created the resource and IAM identities within the account that have the required permission can access the S3 resource. Resource owners can give other identities access to their S3 resources.

Identities that don't own a resource can request access to that resource. Requests to a resource are either authenticated or unauthenticated. Authenticated requests must include a signature value that authenticates the request sender, but unauthenticated requests do not require a signature. We recommend that you grant access only to authenticated users. For more information about request authentication, see Making requests in the *Amazon S3 API Reference*.

Important

We recommend that you don't use the AWS account root user credentials to make authenticated requests. Instead, create an IAM role and grant that role full access. We refer to users with this role as *administrator users*. You can use credentials assigned to the administrator role, instead of AWS account root user credentials, to interact with AWS and perform tasks, such as create a bucket, create users, and grant permissions. For more information, see AWS account root user credentials and IAM user credentials in the *AWS General Reference*, and see Security best practices in IAM in the *IAM User Guide*.

Identities accessing your data in Amazon S3 can be one of the following:

AWS account owner

The AWS account that created the resource. For example, the account that created the bucket. This account owns the resource. For more information, see AWS account root user.

IAM identities in the same account of the AWS account owner

When setting up accounts for new team members who require S3 access, the AWS account owner can use AWS Identity and Access Management (IAM) to create users, groups, and roles. The AWS

account owner can then share resources with these IAM identities. The account owner can also specify the permissions to give the IAM identities, which allow or deny the actions that can be performed on the shared resources.

IAM identities provide increased capabilities, including the ability to require users to enter login credentials before accessing shared resources. By using IAM identities, you can implement a form of IAM multi-factor authentication (MFA) to support a strong identity foundation. An IAM best practice is to create roles for access management instead of granting permissions to each individual user. You assign individual users to the appropriate role. For more information, see Security best practices in IAM.

Other AWS account owners and their IAM identities (cross-account access)

The AWS account owner can also give other AWS account owners, or IAM identities that belong to another AWS account, access to resources.

> **Note**
>
> **Permission delegation** — If an AWS account owns a resource, it can grant those permissions to another AWS account. That account can then delegate those permissions, or a subset of them, to users in the same account. This is referred to as permission delegation. But an account that receives permissions from another account cannot delegate those permissions "cross-account" to another AWS account.

Anonymous users (public access)

The AWS account owner can make resources public. Making a resource public technically shares the resource with *the anonymous user*. Buckets created since April 2023 block all public access by default, unless you change this setting. We recommend that you set your buckets to block public access, and that you only grant access to authenticated users. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

AWS services

The resource owner can grant another AWS service access to an Amazon S3 resource. For example, you can grant the AWS CloudTrail service `s3:PutObject` permission to write log files to your bucket. For more information, see Providing access to an AWS service.

Corporate directory identities

The resource owner can grant users or roles from your corporate directory access to an S3 resource by using S3 Access Grants. For more information about adding your corporate directory to AWS IAM Identity Center, see What is IAM Identity Center?.

Bucket or resource owners

The AWS account that you use to create buckets and upload objects owns those resources. A bucket owner can grant cross-account permissions to another AWS account (or users in another account) to upload objects.

When a bucket owner permits another account to upload objects to a bucket, the bucket owner, by default, owns all objects uploaded to their bucket. However, if both the *Bucket owner enforced* and *Bucket owner preferred* bucket settings are turned off, the AWS account that uploads the objects owns those objects, and the bucket owner does not have permissions on the objects owned by another account, with the following exceptions:

- The bucket owner pays the bills. The bucket owner can deny access to any objects, or delete any objects in the bucket, regardless of who owns them.
- The bucket owner can archive any objects or restore archived objects, regardless of who owns them. Archival refers to the storage class used to store the objects. For more information, see Managing the lifecycle of objects.

Access management tools

Amazon S3 provides a variety of security features and tools. The following is a comprehensive list of these features and tools. You do not need all of these access management tools, but you must use one or more to grant access to your Amazon S3 resources. Proper application of these tools can help make sure that your resources are accessible only to the intended users.

The most commonly used access management tool is an *access policy*. An access policy can be a *resource-based policy* that is attached to an AWS resource, such as a bucket policy for a bucket. An access policy can also be an *identity-based policy* that is attached to an AWS Identity and Access Management (IAM) identity, such as an IAM user, group, or role. Write an access policy to grant AWS accounts and IAM users, groups, and roles permission to perform operations on a resource. For example, you can grant `PUT Object` permission to another AWS account so that the other account can upload objects to your bucket.

An access policy describes who has access to what things. When Amazon S3 receives a request, it must evaluate all of the access policies to determine whether to authorize or deny the request. For more information about how Amazon S3 evaluates these policies, see How Amazon S3 authorizes a request.

The following are the access management tools available in Amazon S3.

Bucket policy

An Amazon S3 bucket policy is a JSON-formatted AWS Identity and Access Management (IAM) resource-based policy that is attached to a particular bucket. Use bucket policies to grant other AWS accounts or IAM identities permissions for the bucket and the objects in it. Many S3 access management use cases can be met by using a bucket policy. With bucket policies, you can personalize bucket access to help make sure that only the identities that you have approved can access resources and perform actions within them. For more information, see Bucket policies for Amazon S3.

The following is an example bucket policy. You express the bucket policy by using a JSON file. This example policy grants an IAM role read permission to all objects in the bucket. It contains one statement named `BucketLevelReadPermissions`, which allows the `s3:GetObject` action (read permission) on objects in a bucket named `amzn-s3-demo-bucket1`. By specifying an IAM role as the `Principal`, this policy grants access to any IAM user with this role. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid":"BucketLevelReadPermissions",
      "Effect":"Allow",
      "Principal": {
     "AWS": "arn:aws:iam::123456789101:role/s3-role"
      },
      "Action":["s3:GetObject"],
      "Resource":["arn:aws:s3:::amzn-s3-demo-bucket/*"]
    }]
  }
```

Note

When creating policies, avoid the use of wildcard characters (*) in the `Principal` element because using a wildcard character allows anyone to access your Amazon S3 resources. Instead, explicitly list users or groups that are allowed to access the bucket, or list conditions that must be met by using a condition clause in the policy. Also, rather than including a wildcard character for the actions of your users or groups, grant them specific permissions when applicable.

Identity-based policy

An identity-based or IAM user policy is a type of AWS Identity and Access Management (IAM) policy. An identity-based policy is a JSON-formatted policy that is attached to IAM users, groups, or roles in your AWS account. You can use identity-based policies to grant an IAM identity access to your buckets or objects. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to AWS resources, including Amazon S3 resources. For more information, see Identity-based policies for Amazon S3.

The following is an example of an identity-based policy. The example policy allows the associated IAM role to perform six different Amazon S3 actions (permissions) on a bucket and the objects in it. If you attach this policy to an IAM role in your account and assign the role to some of your IAM users, the users with this role will be able to perform these actions on the resources (buckets) specified in your policy. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
  {
    "Sid": "AssignARoleActions",
    "Effect": "Allow",
    "Action": [
   "s3:PutObject",
   "s3:GetObject",
   "s3:ListBucket",
   "s3:DeleteObject",
```

```
    "s3:GetBucketLocation"
     ],
     "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "arn:aws:s3:::amzn-s3-demo-bucket"
     ]
     },
   {
     "Sid": "AssignARoleActions2",
     "Effect": "Allow",
     "Action": "s3:ListAllMyBuckets",
     "Resource": "*"
   }
   ]
}
```

S3 Access Grants

Use S3 Access Grants to create access grants to your Amazon S3 data for both identities in corporate identity directories, such as Active Directory, and to AWS Identity and Access Management (IAM) identities. S3 Access Grants helps you manage data permissions at scale. Additionally, S3 Access Grants logs end-user identity and the application used to access the S3 data in AWS CloudTrail. This provides a detailed audit history down to the end-user identity for all access to the data in your S3 buckets. For more information, see Managing access with S3 Access Grants.

Access Points

Amazon S3 Access Points simplifies managing data access at scale for applications that use shared datasets on S3. Access Points are named network endpoints that are attached to a bucket. You can use access points to perform S3 object operations at scale, such as uploading and retrieving objects. A bucket can have up to 10,000 access points attached, and for each access point, you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. S3 Access Points can be associated with buckets in the same account or in another trusted account. Access Points policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy. For more information, see Managing access to shared datasets with access points.

Access control list (ACL)

An ACL is a list of grants identifying the grantee and the permission granted. ACLs grant basic read or write permissions to other AWS accounts. ACLs use an Amazon S3–specific XML schema. An ACL is a type of AWS Identity and Access Management (IAM) policy. An object ACL is used to manage access to an object, and a bucket ACL is used to manage access to a bucket. With bucket policies, there is a single policy for the entire bucket, but object ACLs are specified for each object. We recommend that you keep ACLs turned off, except in circumstances where you must individually control access for each object. For more information about using ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Warning**
>
> The majority of modern use cases in Amazon S3 do not require the use of ACLs.

The following is an example bucket ACL. The grant in the ACL shows a bucket owner that has full control permission.

```
<?xml version="1.0" encoding="UTF-8"?>
 <AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
   <ID>Owner-Canonical-User-ID</ID>
  </Owner>
 <AccessControlList>
  <Grant>
   <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Canonical
 User">
    <ID>Owner-Canonical-User-ID</ID>
   </Grantee>
   <Permission>FULL_CONTROL</Permission>
  </Grant>
 </AccessControlList>
</AccessControlPolicy>
```

Object Ownership

To manage access to your objects, you must be the owner of the object. You can use the Object Ownership bucket-level setting to control ownership of objects uploaded to your bucket. Also, use Object Ownership to turn on ACLs. By default, Object Ownership is set to the *Bucket owner*

enforced setting and all ACLs are turned off. When ACLs are turned off, the bucket owner owns all of the objects in the bucket and exclusively manages access to data. To manage access, the bucket owner uses policies or another access management tool, excluding ACLs. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

Object Ownership has three settings that you can use both to control ownership of objects that are uploaded to your bucket and to turn on ACLs:

ACLs turned off

- **Bucket owner enforced (default)** – ACLs are turned off, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs do not affect permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

ACLs turned on

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Additional best practices

Consider using the following bucket settings and tools to help protect data in transit and at rest, both of which are crucial in maintaining the integrity and accessibility of your data:

- **Block Public Access** — Do not turn off the default bucket-level setting *Block Public Access*. This setting blocks public access to your data by default. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.
- **S3 Versioning** — For data integrity, you can implement the S3 Versioning bucket setting, which versions your objects as you make updates, instead of overwriting them. You can use S3 Versioning to preserve, retrieve, and restore a previous version, if needed. For information about S3 Versioning, see Retaining multiple versions of objects with S3 Versioning.
- **S3 Object Lock** — S3 Object Lock is another setting that you can implement for achieving data integrity. This feature can implement a write-once-read-many (WORM) model to store objects immutably. For information about Object Lock, see Locking objects with Object Lock.

- **Object encryption** — Amazon S3 offers several object encryption options that protect data in transit and at rest. *Server-side encryption* encrypts your object before saving it on disks in its data centers and then decrypts it when you download the objects. If you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For more information, see Protecting data with server-side encryption. S3 encrypts newly uploaded objects by default. For more information, see Setting default server-side encryption behavior for Amazon S3 buckets. *Client-side encryption* is the act of encrypting data before sending it to Amazon S3. For more information, see Protecting data by using client-side encryption.
- **Signing methods** — Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see Authenticating Requests (AWS Signature Version 4) and Signature Version 4 signing process.

Actions

For a complete list of S3 permissions and condition keys, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Actions

The AWS Identity and Access Management (IAM) actions for Amazon S3 are the possible actions that can be performed on an S3 bucket or object. You grant these actions to identities so they can act on your S3 resources. Examples of S3 actions are `s3:GetObject` to read objects in a bucket, and `s3:PutObject` to write objects to a bucket.

Condition keys

In addition to actions, IAM condition keys are limited to granting access to only when a condition is met. Condition keys are optional.

Note

In a resource-based access policy, such as a bucket policy, or in an identity-based policy, you can specify the following:

- An action or an array of actions in the `Action` element of the policy statement.
- In the `Effect` element of the policy statement, you can specify `Allow` to grant the actions listed, or you can specify `Deny` to block the listed actions. To further maintain the practice of least privileges, `Deny` statements in the `Effect` element of the access policy should be as broad as possible, and `Allow` statements should be as narrow as possible. `Deny` effects paired with the `s3:*` action are another good way to implement opt-in best practices for the identities that are included in policy condition statements.
- A condition key in the `Condition` element of a policy statement.

Access management use cases

Amazon S3 provides resource owners with a variety of tools for granting access. The S3 access management tool that you use depends on the S3 resources that you want to share, the identities that you are granting access to, and the actions that you want to allow or deny. You might want to use one or a combination of S3 access management tools to manage access to your S3 resources.

In most cases, you can use an access policy to manage permissions. An access policy can be a resource-based policy, which is attached to a resource, such as a bucket, or another Amazon S3 resource (S3 resources). An access policy can also be an identity-based policy, which is attached to an AWS Identity and Access Management (IAM) user, group, or role in your account. You might find that a bucket policy works better for your use case. For more information, see Bucket policies for Amazon S3. Alternatively, with AWS Identity and Access Management (IAM), you can create IAM users, groups, and roles within your AWS account and manage their access to buckets and objects through identity-based policies. For more information, see Identity-based policies for Amazon S3.

To help you navigate these access management options, the following are common Amazon S3 customer use cases and recommendations for each of the S3 access management tools.

The AWS account owner wants to share buckets only with users within the same account

All access management tools can fulfill this basic use case. We recommend the following access management tools for this use case:

- **Bucket policy** – If you want to grant access to one bucket or a small number of buckets, or if your bucket access permissions are similar from bucket to bucket, use a bucket policy. With bucket policies, you manage one policy for each bucket. For more information, see Bucket policies for Amazon S3.
- **Identity-based policy** – If you have a very large number of buckets with different access permissions for each bucket, and only a few user roles to manage, you can use an IAM policy for users, groups, or roles. IAM policies are also a good option if you are managing user access to other AWS resources, as well as Amazon S3 resources. For more information, see Example 1: Bucket owner granting its users bucket permissions.
- **S3 Access Grants** – You can use S3 Access Grants to grant access to your S3 buckets, prefixes, or objects. S3 Access Grants allows you to specify varying object-level permissions at scale; whereas, bucket policies are limited to 20 KB in size. For more information, see Getting started with S3 Access Grants.
- **Access Points** – You can use Access Points, which are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing access to shared datasets with access points.

The AWS account owner wants to share buckets or objects with users from another AWS account (cross-account)

To grant permission to another AWS account, you must use a bucket policy or one of the following recommended access management tools. You cannot use an identity-based access policy for this use case. For more information about granting cross-account access, see How do I provide cross-account access to objects that are in Amazon S3 buckets?

We recommend the following access management tools for this use case:

- **Bucket policy** – With bucket policies, you manage one policy for each bucket. For more information, see Bucket policies for Amazon S3.

- **S3 Access Grants** – You can use S3 Access Grants to grant cross-account permissions to your S3 buckets, prefixes, or objects. You can use S3 Access Grants to specify varying object-level permissions at scale; whereas, bucket policies are limited to 20 KB in size. For more information, see Getting started with S3 Access Grants.
- **Access Points** – You can use Access Points, which are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing access to shared datasets with access points.

The AWS account owner or bucket owner must grant permissions at the object-level or prefix-level, and these permissions vary from object to object or prefix to prefix

In a bucket policy, for example, you can grant access to the objects within a bucket that share a specific key name prefix or have a specific tag. You can grant read permission on objects starting with the key name prefix `logs/`. However, if your access permissions vary by object, granting permissions to individual objects by using a bucket policy might not be practical, especially since bucket policies are limited to 20 KB in size.

We recommend the following access management tools for this use case:

- **S3 Access Grants** – You can use S3 Access Grants to manage object-level or prefix-level permissions. Unlike bucket policies, you can use S3 Access Grants to specify varying object-level permissions at scale. Bucket policies are limited to 20 KB in size. For more information, see Getting started with S3 Access Grants.
- **Access Points** – You can use access points to manage object-level or prefix-level permissions. Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing access to shared datasets with access points.
- **ACLs** – We do not recommend using Access Control Lists (ACLs), especially because ACLs are limited to 100 grants per object. However, if you choose to turn on ACLs, in your Bucket Settings, set *Object Ownership* to *Bucket owner preferred* and *ACLs enabled*. With this setting, new objects that are written with the `bucket-owner-full-control` canned ACL are automatically owned by the bucket owner rather than the object writer. You can then use object ACLs, which is an

XML-formatted access policy, to grant other users access to the object. For more information, see Access control list (ACL) overview.

The AWS account owner or bucket owner wants to limit bucket access only to specific account IDs

We recommend the following access management tools for this use case:

- **Bucket policy** – With bucket policies, you manage one policy for each bucket. For more information, see Bucket policies for Amazon S3.
- **Access Points** – Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. For more information, see Managing access to shared datasets with access points.

The AWS account owner or bucket owner wants distinct endpoints for every user or application that accesses their data

We recommend the following access management tool for this use case:

- **Access Points** – Access Points are named network endpoints that are attached to a bucket. A bucket can have up to 10,000 access points attached, and for each access point you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For more information, see Managing access to shared datasets with access points.

The AWS account owner or bucket owner must manage access from Virtual Private Cloud (VPC) endpoints for S3

Virtual Private Cloud (VPC) endpoints for Amazon S3 are logical entities within a VPC that allow connectivity only to S3. We recommend the following access management tools for this use case:

- **Buckets in a VPC setting** – You can use a bucket policy to control who is allowed to access your buckets and which VPC endpoints they can access. For more information, see Controlling access from VPC endpoints with bucket policies.

- **Access Points** – If you choose to set up access points, you can use an access point policy. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point. For more information, see Managing access to shared datasets with access points.

The AWS account owner or bucket owner must make a static website publicly available

With S3, you can host a static website and allow anyone to view the content of the website, which is hosted from an S3 bucket.

We recommend the following access management tools for this use case:

- **Amazon CloudFront** – This solution allows you to host an Amazon S3 static website to the public while also continuing to block all public access to a bucket's content. If you want to keep all four S3 Block Public Access settings enabled and host an S3 static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Also, Amazon S3 static websites that do not use this solution can only support HTTP endpoints. CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks.

  For more information, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.
- **Making your Amazon S3 bucket publicly accessible** – You can configure a bucket to be used as a publicly accessed static website.

  > **Warning**
  >
  > We do not recommend this method. Instead, we recommend you use Amazon S3 static websites as a part of Amazon CloudFront. For more information, see the previous option, or see Getting started with a secure static website.

  To create an Amazon S3 static website, without Amazon CloudFront, first, you must turn off all Block Public Access settings. When writing the bucket policy for your static website, make sure that you allow only `s3:GetObject` actions, not `ListObject` or `PutObject` permissions. This

helps make sure that users cannot view all the objects in your bucket or add their own content. For more information, see Setting permissions for website access.

The AWS account owner or bucket owner wants to make the content of a bucket publicly available

When creating a new Amazon S3 bucket, the *Block Public Access* setting is enabled by default. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

We do not recommend allowing public access to your bucket. However, if you must do so for a particular use case, we recommend the following access management tool for this use case:

- **Disable Block Public Access setting** – A bucket owner can allow unauthenticated requests to the bucket. For example, unauthenticated PUT Object requests are allowed when a bucket has a public bucket policy, or when a bucket ACL grants public access. All unauthenticated requests are made by other arbitrary AWS users, or even unauthenticated, anonymous users. This user is represented in ACLs by the specific canonical user ID `65a011a29cdf8ec533ec3d1ccaae921c`. If an object is uploaded to a `WRITE` or `FULL_CONTROL`, then this specifically grants access to the All Users group or the anonymous user. For more information about public bucket policies and public access control lists (ACLs), see The meaning of "public".

The AWS account owner or bucket owner has exceeded access policy size limits

Both bucket policies and identity-based policies have a 20 KB size limit. If your access permission requirements are complex, you might exceed this size limit.

We recommended the following access management tools for this use case:

- **Access Points** – Use access points if this works with your use case. With access points, each bucket has multiple named network endpoints, each with its own access point policy that works with the underlying bucket policy. However, access points can only act on objects, not buckets, and does not support cross-Region replication. For more information, see Managing access to shared datasets with access points.
- **S3 Access Grants** – Use S3 Access Grants, which supports a very large number of grants that give access to buckets, prefixes, or objects. For more information, see Getting started with S3 Access Grants.

The AWS account owner or admin role wants to grant bucket, prefix, or object access directly to users or groups in a corporate directory

Instead of managing users, groups, and roles through AWS Identity and Access Management (IAM), you can add your corporate directory to AWS IAM Identity Center. For more information, see What is IAM Identity Center?.

After you add your corporate directory to AWS IAM Identity Center, we recommend that you use the following access management tool to grant corporate directory identities access to your S3 resources:

- **S3 Access Grants** – Use S3 Access Grants, which supports granting access to users or roles in your corporate directory. For more information, see Getting started with S3 Access Grants.

The AWS account owner or bucket owner wants to give the AWS CloudFront service access to write CloudFront logs to an S3 bucket

We recommended the following access management tool for this use case:

- **Bucket ACL** – The only recommended use case for bucket ACLs is to grant permissions to certain AWS services, such as the Amazon CloudFront `awslogsdelivery` account. When you create or update a distribution and turn on CloudFront logging, CloudFront updates the bucket ACL to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the *Bucket owner enforced* setting for S3 Object Ownership to turn off ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

You, as the bucket owner, want to maintain full control of objects that are added to the bucket by other users

You can grant other accounts access to upload objects to your bucket by using a bucket policy, access point, or S3 Access Grants. If you have granted cross-account access to your bucket, you can make sure that any objects uploaded to your bucket remain under your full control.

We recommended the following access management tool for this use case:

- **Object Ownership** – Keep the bucket-level setting *Object Ownership* at the default *Bucket owner enforced* setting.

Access management troubleshooting

The following resources can help you troubleshoot any issues with S3 access management:

Troubleshooting Access Denied (403 Forbidden) errors

If you encounter access denial issues, check the account-level and bucket-level settings. Also, check the access management feature that you are using to grant access to make sure that the policy, setting, or configuration is correct. For more information about common causes of Access Denied (403 Forbidden) errors in Amazon S3, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3.

IAM Access Analyzer for S3

If you do not want to make any of your resources publicly available, or if you want to limit public access to your resources, you can use IAM Access Analyzer for S3. On the Amazon S3 console, use IAM Access Analyzer for S3 to review all buckets that have bucket access control lists (ACLs), bucket policies, or access point policies that grant public or shared access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single action. We recommend that you block all public access to your buckets, unless you require public access to support a specific use case. Before you block all public access, make sure that your applications will continue to work correctly without public access. For more information, see Blocking public access to your Amazon S3 storage.

You can also review your bucket-level permission settings to configure detailed levels of access. For specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer.

To use IAM Access Analyzer for S3 on the Amazon S3 console, you must visit the IAM Console and create an account-level analyzer in IAM Access Analyzer for each individual Region.

For more information about IAM Access Analyzer for S3, see Reviewing bucket access using IAM Access Analyzer for S3.

Logging and monitoring

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon S3 solutions so that you can more easily debug an access failure. Logging can provide insight into any errors users are receiving, and when and what requests are made. AWS provides several tools for monitoring your Amazon S3 resources, such as the following:

- AWS CloudTrail
- Amazon S3 Access Logs
- AWS Trusted Advisor
- Amazon CloudWatch

For more information, see Logging and monitoring in Amazon S3.

Identity and Access Management for Amazon S3

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon S3 resources. IAM is an AWS service that you can use with no additional charge.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How Amazon S3 works with IAM
- How Amazon S3 authorizes a request
- Required permissions for Amazon S3 API operations
- Policies and permissions in Amazon S3
- Bucket policies for Amazon S3
- Identity-based policies for Amazon S3
- Walkthroughs that use policies to manage access to your Amazon S3 resources
- Using service-linked roles for Amazon S3 Storage Lens
- Troubleshooting Amazon S3 identity and access
- AWS managed policies for Amazon S3

Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see Troubleshooting Amazon S3 identity and access)
- **Service administrator** - determine user access and submit permission requests (see How Amazon S3 works with IAM)
- **IAM administrator** - write policies to manage access (see Identity-based policies for Amazon S3)

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access AWS using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity with specific permissions that provides temporary credentials. You can assume a role by switching from a user to an IAM role (console) or by calling an AWS CLI or AWS API operation. For more information, see Methods to assume a role in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must specify a principal in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see Service control policies in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon S3 works with IAM

Before you use IAM to manage access to Amazon S3, learn what IAM features are available to use with Amazon S3.

IAM features you can use with Amazon S3

IAM feature	Amazon S3 support
Identity-based policies	Yes
Resource-based policies	Yes
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	Yes

IAM feature	Amazon S3 support
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Forward access sessions (FAS)	Yes
Service roles	Yes
Service-linked roles	Partial

To get a high-level view of how Amazon S3 and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Identity-based policies for Amazon S3

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Amazon S3

To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.

Resource-based policies within Amazon S3

Supports resource-based policies: Yes

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that

support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

The Amazon S3 service supports *bucket policies*, *access points policies*, and *access grants*:

- Bucket policies are resource-based policies that are attached to an Amazon S3 bucket. A bucket policy defines which principals can perform actions on the bucket.
- Access point policies are resource-based polices that are evaluated in conjunction with the underlying bucket policy.
- Access grants are a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. For information about S3 Access Grants, see Managing access with S3 Access Grants.

Principals for bucket policies

The `Principal` element specifies the user, account, service, or other entity that is either allowed or denied access to a resource. The following are examples of specifying `Principal`. For more information, see Principal in the *IAM User Guide*.

Grant permissions to an AWS account

To grant permissions to an AWS account, identify the account using the following format.

```
"AWS":"account-ARN"
```

The following are examples.

```
"Principal":{"AWS":"arn:aws:iam::AccountIDWithoutHyphens:root"}
```

```
"Principal":{"AWS":
["arn:aws:iam::AccountID1WithoutHyphens:root","arn:aws:iam::AccountID2WithoutHyphens:root"]}
```

> **Note**
>
> The examples above grant permissions to the root user, which delegates permissions to the account level. However, IAM policies are still required on the specific roles and users in the account.

Grant permissions to an IAM user

To grant permission to an IAM user within your account, you must provide an `"AWS":"user-ARN"` name-value pair.

```
"Principal":{"AWS":"arn:aws:iam::account-number-without-hyphens:user/username"}
```

For detailed examples that provide step-by-step instructions, see Example 1: Bucket owner granting its users bucket permissions and Example 3: Bucket owner granting permissions to objects it does not own.

> **Note**
>
> If an IAM identity is deleted after you update your bucket policy, the bucket policy will show a unique identifier in the principal element instead of an ARN. These unique IDs are never reused, so you can safely remove principals with unique identifiers from all of your policy statements. For more information about unique identifiers, see IAM identifiers in the *IAM User Guide*.

Grant anonymous permissions

> **Warning**
>
> Use caution when granting anonymous access to your Amazon S3 bucket. When you grant anonymous access, anyone in the world can access your bucket. We highly recommend that you never grant any kind of anonymous write access to your S3 bucket.

To grant permission to everyone, also referred as anonymous access, you set the wildcard (`"*"`) as the `Principal` value. For example, if you configure your bucket as a website, you want all the objects in the bucket to be publicly accessible.

```
"Principal":"*"
```

```
"Principal":{"AWS":"*"}
```

Using `"Principal": "*"` with an `Allow` effect in a resource-based policy allows anyone, even if they're not signed in to AWS, to access your resource.

Using `"Principal" : { "AWS" : "*" }` with an `Allow` effect in a resource-based policy allows any root user, IAM user, assumed-role session, or federated user in any account in the same partition to access your resource.

For anonymous users, these two methods are equivalent. For more information, see All principals in the *IAM User Guide*.

You cannot use a wildcard to match part of a principal name or ARN.

> **Important**
>
> In AWS access control policies, the Principals "*" and {"AWS": "*"} behave identically.

Restrict resource permissions

You can also use resource policy to restrict access to resources that would otherwise be available to IAM principals. Use a `Deny` statement to prevent access.

The following example blocks access if a secure transport protocol isn't used:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "DenyBucketAccessIfSTPNotUsed",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
```

```
      "Condition": {
        "Bool": {
          "aws:SecureTransport": "false"
        }
      }
    }
  ]
}
```

Using `"Principal": "*"` so that this restriction applies to everyone is a best practice for this policy, instead of attempting to deny access only to specific accounts or principals using this method.

Require access through CloudFront URLs

You can require that your users access your Amazon S3 content only by using CloudFront URLs instead of Amazon S3 URLs. To do this, create a CloudFront origin access control (OAC). Then, change the permissions on your S3 data. In your bucket policy, you can set CloudFront as the Principal as follows:

```
"Principal":{"Service":"cloudfront.amazonaws.com"}
```

Use a `Condition` element in the policy to allow CloudFront to access the bucket only when the request is on behalf of the CloudFront distribution that contains the S3 origin.

```
       "Condition": {
          "StringEquals": {
             "AWS:SourceArn":
 "arn:aws:cloudfront::111122223333:distribution/CloudFront-distribution-ID"
          }
       }
```

For more information about requiring S3 access through CloudFront URLs, see Restricting access to an Amazon Simple Storage Service origin in the *Amazon CloudFront Developer Guide*. For more information about the security and privacy benefits of using Amazon CloudFront, see Configuring secure access and restricting access to content.

Resource-based policy examples for Amazon S3

- To view policy examples for Amazon S3 buckets, see Bucket policies for Amazon S3.
- To view policy examples for access points, see Configuring IAM policies for using access points.

Policy actions for Amazon S3

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

The following shows different types of mapping relationship between S3 API operations and the required policy actions.

- One-to-one mapping with the same name. For example, to use the `PutBucketPolicy` API operation, the `s3:PutBucketPolicy` policy action is required.
- One-to-one mapping with different names. For example, to use the `ListObjectsV2` API operation, the `s3:ListBucket` policy action is required.
- One-to-many mapping. For example, to use the `HeadObject` API operation, the `s3:GetObject` is required. Also, when you use S3 Object Lock and want to get an object's Legal Hold status or retention settings, the corresponding `s3:GetObjectLegalHold` or `s3:GetObjectRetention` policy actions are also required before you can use the `HeadObject` API operation.
- Many-to-one mapping. For example, to use the `ListObjectsV2` or `HeadBucket` API operations, the `s3:ListBucket` policy action is required.

To see a list of Amazon S3 actions for use in policies, see Actions defined by Amazon S3 in the *Service Authorization Reference*. For a complete list of Amazon S3 API operations, see Amazon S3 API Actions in the *Amazon Simple Storage Service API Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Policy actions in Amazon S3 use the following prefix before the action:

```
s3
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "s3:action1",
      "s3:action2"
         ]
```

Bucket operations

Bucket operations are S3 API operations that operate on the bucket resource type. For example, `CreateBucket`, `ListObjectsV2`, and `PutBucketPolicy`. S3 policy actions for bucket operations require the `Resource` element in bucket policies or IAM identity-based policies to be the S3 bucket type Amazon Resource Name (ARN) identifier in the following example format.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
```

The following bucket policy grants the user *Akua* with account *12345678901* the `s3:ListBucket` permission to perform the ListObjectsV2 API operation and list objects in an S3 bucket.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to list objects in the bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Akua"
            },
            "Action": [
            "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
```

```
        }
    ]
}
```

Bucket operations in policies for access points for general purpose buckets

Permissions granted in an access point for general purpose buckets policy are effective only if the underlying bucket allows the same permissions. When you use S3 Access Points, you must delegate access control from the bucket to the access point or add the same permissions in the access point policies to the underlying bucket's policy. For more information, see Configuring IAM policies for using access points. In access point policies, S3 policy actions for bucket operations require you to use the access point ARN for the `Resource` element in the following format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:ListBucket` permission to perform the ListObjectsV2 API operation through the S3 access point named *example-access-point*. This permission allows *Akua* to list the objects in the bucket that's associated with *example-access-point*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAkuaToListObjectsInBucketThroughAccessPoint",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Akua"
            },
            "Action": [
            "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:us-west-2:111122223333:accesspoint/example-
access-point"
        }
    ]
}
```

> **Note**
>
> Not all bucket operations are supported by access points for general purpose buckets. For more information, see Access points compatibility with S3 operations.

Bucket operations in policies for access points for directory buckets

Permissions granted in an access points for directory buckets policy are effective only if the underlying bucket allows the same permissions. When you use S3 Access Points, you must delegate access control from the bucket to the access point or add the same permissions in the access point policies to the underlying bucket's policy. For more information, see Configuring IAM policies for using access points for directory buckets. In access point policies, S3 policy actions for bucket operations require you to use the access point ARN for the `Resource` element in the following format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point--usw2-az1--xa-s3"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:ListBucket` permission to perform the ListObjectsV2 API operation through the access point named *example-access-point--usw2-az1--xa-s3*. This permission allows *Akua* to list the objects in the bucket that's associated with *example-access-point--usw2-az1--xa-s3*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAkuaToListObjectsInTheBucketThroughAccessPoint",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Akua"
            },
            "Action": [
            "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3express:us-east-1:111122223333:accesspoint/
example-access-point-usw2-az1-xa-s3"
```

```
        }
    ]
}
```

> **Note**
>
> Not all bucket operations are supported by access points for directory buckets. For more information, see Object operations for access points for directory buckets.

Object operations

Object operations are S3 API operations that act upon the object resource type. For example, `GetObject`, `PutObject`, and `DeleteObject`. S3 policy actions for object operations require the `Resource` element in policies to be the S3 object ARN in the following example formats.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/*"
```

> **Note**
>
> The object ARN must contain a forward slash after the bucket name, as seen in the previous examples.

The following bucket policy grants the user *Akua* with account *12345678901* the `s3:PutObject` permission. This permission allows *Akua* to use the PutObject API operation to upload objects to the S3 bucket named *amzn-s3-demo-bucket*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to upload objects",
```

```
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Akua"
            },
            "Action": [
            "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Object operations in access point policies

When you use S3 Access Points to control access to object operations, you can use access point policies. When you use access point policies, S3 policy actions for object operations require you to use the access point ARN for the `Resource` element in the following format: `arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource`. For object operations that use access points, you must include the `/object/` value after the whole access point ARN in the `Resource` element. Here are some examples.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point/object/
*"
```

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point/
object/prefix/*"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:GetObject` permission. This permission allows *Akua* to perform the GetObject API operation through the access point named *example-access-point* on all objects in the bucket that's associated with the access point.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to get objects through access point",
```

```
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Akua"
            },
            "Action": [
            "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:us-east-1:111122223333:accesspoint/example-
access-point/object/*"
        }
    ]
}
```

> **Note**
>
> Not all object operations are supported by access points. For more information, see Access points compatibility with S3 operations.

Object operations in policies for access points for directory buckets

When you use access points for directory buckets to control access to object operations, you can use access point policies. When you use access point policies, S3 policy actions for object operations require you to use the access point ARN for the `Resource` element in the following format: `arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource`. For object operations that use access points, you must include the `/object/` value after the whole access point ARN in the `Resource` element. Here are some examples.

```
"Resource": "arn:aws:s3express:us-west-2:123456789012:accesspoint/example-access-
point--usw2-az1--xa-s3/object/*"
```

```
"Resource": "arn:aws:s3express:us-west-2:123456789012:accesspoint/example-access-
point--usw2-az1--xa-s3/object/prefix/*"
```

The following access point policy grants the user *Akua* with account *12345678901* the `s3:GetObject` permission. This permission allows *Akua* to perform the GetObject API operation through the access point named *example-access-point--usw2-az1--xa-s3* on all objects in the bucket that's associated with the access point.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow Akua to get objects through access point",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::12345678901:user/Akua"
            },
            "Action": ["s3express:CreateSession", "s3:GetObject"],
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point--usw2-az1--xa-s3/object/*"
        }
    ]
}
```

> **Note**
>
> Not all object operations are supported by access points for directory buckets. For more information, see Object operations for access points for directory buckets.

Access point for general purpose bucket operations

Access point operations are S3 API operations that operate on the `accesspoint` resource type. For example, `CreateAccessPoint`, `DeleteAccessPoint`, and `GetAccessPointPolicy`. S3 policy actions for access point operations can only be used in IAM identity-based policies, not in bucket policies or access point policies. Access points operations require the `Resource` element to be the access point ARN in the following example format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point"
```

The following IAM identity-based policy grants the `s3:GetAccessPointPolicy` permission to perform the GetAccessPointPolicy API operation on the S3 access point named *example-access-point*.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":
 "GrantPermissionToRetrieveTheAccessPointPolicyOfAccessPointExampleAccessPoint",
            "Effect": "Allow",
            "Action": [
            "s3:GetAccessPointPolicy"
            ],
            "Resource": "arn:aws:s3:*:123456789012:accesspoint/example-access-
point"
        }
    ]
}
```

When you use Access Points, to control access to bucket operations, see Bucket operations in policies for access points for general purpose buckets; to control access to object operations, see Object operations in access point policies. For more information about how to configure access point policies, see Configuring IAM policies for using access points.

Access point for directory buckets operations

Access point for directory buckets operations are S3 API operations that operate on the `accesspoint` resource type. For example, `CreateAccessPoint`, `DeleteAccessPoint`, and `GetAccessPointPolicy`. S3 policy actions for access point operations can only be used in IAM identity-based policies, not in bucket policies or access point policies. Access points for directory buckets operations require the `Resource` element to be the access point ARN in the following example format.

```
"Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/example-access-point--usw2-
az1--xa-s3"
```

The following IAM identity-based policy grants the `s3express:GetAccessPointPolicy` permission to perform the GetAccessPointPolicy API operation on the access point named *example-access-point--usw2-az1--xa-s3*.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":
 "GrantPermissionToRetrieveTheAccessPointPolicyOfAccessPointExampleAccessPointUsw2Az1XaS3
            "Effect": "Allow",
            "Action": [
            "s3express:CreateSession","s3express:GetAccessPointPolicy"
            ],
            "Resource": "arn:aws:s3:*:111122223333:accesspoint/example-access-
point"
        }
    ]
}
```

The following IAM identity-based policy grants the `s3express:CreateAccessPoint` permission to create an access points for directory buckets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Grant CreateAccessPoint.",
            "Principal": "*",
            "Action": [
                "s3express:CreateSession",
                "s3express:CreateAccessPoint"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

The following IAM identity-based policy grants the `s3express:PutAccessPointScope` permission to create access point scope for access points for directory buckets.

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "Grant PutAccessPointScope",
            "Principal": "*",
            "Action": [
                "s3express:CreateSession",
                "s3express:CreateAccessPoint",
                "s3express:PutAccessPointScope"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

When you use access points for directory buckets to control access to bucket operations, see Bucket operations in policies for access points for directory buckets; to control access to object operations, see Object operations in policies for access points for directory buckets. For more information about how to configure access points for directory buckets policies, see Configuring IAM policies for using access points for directory buckets.

Object Lambda Access Point operations

With Amazon S3 Object Lambda, you can add your own code to Amazon S3 `GET`, `LIST`, and `HEAD` requests to modify and process data as it is returned to an application. You can make requests through an Object Lambda Access Point, which works the same as making requests through other access points. For more information, see Transforming objects with S3 Object Lambda.

For more information about how to configure policies for Object Lambda Access Point operations, see Configuring IAM policies for Object Lambda Access Points.

Multi-Region Access Point operations

A Multi-Region Access Point provides a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Region. You can use a Multi-Region Access Point to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. For more information, see Managing multi-Region traffic with Multi-Region Access Points.

For more information about how to configure policies for Multi-Region Access Point operations, see Multi-Region Access Point policy examples.

Batch job operations

(Batch Operations) job operations are S3 API operations that operate on the job resource type. For example, `DescribeJob` and `CreateJob`. S3 policy actions for job operations can only be used in IAM identity-based policies, not in bucket policies. Also, job operations require the `Resource` element in IAM identity-based policies to be the `job` ARN in the following example format.

```
"Resource": "arn:aws:s3:*:123456789012:job/*"
```

The following IAM identity-based policy grants the `s3:DescribeJob` permission to perform the DescribeJob API operation on the S3 Batch Operations job named *`example-job`*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDescribingBatchOperationJob",
            "Effect": "Allow",
            "Action": [
            "s3:DescribeJob"
            ],
            "Resource": "arn:aws:s3:*:111122223333:job/example-job"
        }
    ]
}
```

S3 Storage Lens configuration operations

For more information about how to configure S3 Storage Lens configuration operations, see Setting Amazon S3 Storage Lens permissions.

Account operations

Account operations are S3 API operations that operate on the account level. For example, `GetPublicAccessBlock` (for account). Account isn't a resource type defined by Amazon S3. S3 policy actions for account operations can only be used in IAM identity-based policies, not in bucket policies. Also, account operations require the `Resource` element in IAM identity-based policies to be `"*"`.

The following IAM identity-based policy grants the `s3:GetAccountPublicAccessBlock` permission to perform the account-level GetPublicAccessBlock API operation and retrieve the account-level Public Access Block settings.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowRetrievingTheAccountLevelPublicAccessBlockSettings",
         "Effect":"Allow",
         "Action":[
            "s3:GetAccountPublicAccessBlock"
         ],
         "Resource":[
            "*"
         ]
       }
    ]
}
```

Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.
- To view examples of Amazon S3 resource-based policies, see Bucket policies for Amazon S3 and Configuring IAM policies for using access points.

Policy resources for Amazon S3

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't

support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Some Amazon S3 API actions support multiple resources. For example, `s3:GetObject` accesses *example-resource-1* and *example-resource-2*, so a principal must have permissions to access both resources. To specify multiple resources in a single statement, separate the ARNs with commas, as shown in the following example.

```
"Resource": [
      "example-resource-1",
      "example-resource-2"
```

Resources in Amazon S3 are buckets, objects, access points, or jobs. In a policy, use the Amazon Resource Name (ARN) of the bucket, object, access point, or job to identify the resource.

To see a complete list of Amazon S3 resource types and their ARNs, see Resources defined by Amazon S3 in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Amazon S3.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Wildcard characters in resource ARNs

You can use wildcard characters as part of the resource ARN. You can use the wildcard characters (* and ?) within any ARN segment (the parts separated by colons). An asterisk (*) represents any combination of zero or more characters, and a question mark (?) represents any single character. You can use multiple * or ? characters in each segment. However, a wildcard character can't span segments.

- The following ARN uses the * wildcard character in the `relative-ID` part of the ARN to identify all objects in the *amzn-s3-demo-bucket* bucket.

  ```
  arn:aws:s3:::amzn-s3-demo-bucket/*
  ```

- The following ARN uses * to indicate all S3 buckets and objects.

  ```
  arn:aws:s3:::*
  ```

- The following ARN uses both of the wildcard characters, * and ?, in the `relative-ID` part. This ARN identifies all objects in buckets such as *amzn-s3-demo-example1bucket*, *amzn-s3-demo-example2bucket*, *amzn-s3-demo-example3bucket*, and so on.

```
arn:aws:s3:::amzn-s3-demo-example?bucket/*
```

Policy variables for resource ARNs

You can use policy variables in Amazon S3 ARNs. At policy-evaluation time, these predefined variables are replaced by their corresponding values. Suppose that you organize your bucket as a collection of folders, with one folder for each of your users. The folder name is the same as the username. To grant users permission to their folders, you can specify a policy variable in the resource ARN:

```
arn:aws:s3:::bucket_name/developers/${aws:username}/
```

At runtime, when the policy is evaluated, the variable `${aws:username}` in the resource ARN is substituted with the username of the person who is making the request.

Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.
- To view examples of Amazon S3 resource-based policies, see Bucket policies for Amazon S3 and Configuring IAM policies for using access points.

Policy condition keys for Amazon S3

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

Each Amazon S3 condition key maps to the same name request header allowed by the API on which the condition can be set. Amazon S3-specific condition keys dictate the behavior of the same name request headers. For example, the condition key `s3:VersionId` used to grant conditional permission for the
`s3:GetObjectVersion`
permission defines behavior of the `versionId` query parameter that you set in a GET Object request.

To see a list of Amazon S3 condition keys, see Condition keys for Amazon S3 in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon S3.

Example: Restricting object uploads to objects with a specific storage class

Suppose that Account A, represented by account ID *123456789012*, owns a bucket. The Account A administrator wants to restrict *Dave*, a user in Account A, so that *Dave* can upload objects to the bucket only if the object is stored in the `STANDARD_IA` storage class. To restrict object uploads to a specific storage class, the Account A administrator can use the `s3:x-amz-storage-class` condition key, as shown in the following example bucket policy.

JSON

```
{
                "Version":"2012-10-17",
                "Statement": [
                  {
                    "Sid": "statement1",
                    "Effect": "Allow",
                    "Principal": {
                      "AWS": "arn:aws:iam::123456789012:user/Dave"
                    },
                    "Action": "s3:PutObject",
                    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
                    "Condition": {
                      "StringEquals": {
                        "s3:x-amz-storage-class": [
                          "STANDARD_IA"
                        ]
                      }
                    }
                  }
```

```
            ]
        }
```

In the example, the `Condition` block specifies the `StringEquals` condition that is applied to the specified key-value pair, `"s3:x-amz-storage-class":["STANDARD_IA"]`. There is a set of predefined keys that you can use in expressing a condition. The example uses the `s3:x-amz-storage-class` condition key. This condition requires the user to include the `x-amz-storage-class` header with value `STANDARD_IA` in every `PutObject` request.

Policy examples for Amazon S3

- To view examples of Amazon S3 identity-based policies, see Identity-based policies for Amazon S3.
- To view examples of Amazon S3 resource-based policies, see Bucket policies for Amazon S3 and Configuring IAM policies for using access points.

ACLs in Amazon S3

Supports ACLs: Yes

In Amazon S3, access control lists (ACLs) control which AWS accounts have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

> **Important**
>
> A majority of modern use cases in Amazon S3 no longer require the use of ACLs.

For information about using ACLs to control access in Amazon S3, see Managing access with ACLs.

ABAC with Amazon S3

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

For information about resources that support ABAC in Amazon S3, see Using tags for attribute-based access control (ABAC).

To view example identity-based policies for limiting access to S3 Batch Operations jobs based on tags, see Controlling permissions for Batch Operations using job tags.

ABAC and object tags

In ABAC policies, objects use `s3:` tags instead of `aws:` tags. To control access to objects based on object tags, you provide tag information in the Condition element of a policy using the following tags:

- `s3:ExistingObjectTag/tag-key`
- `s3:RequestObjectTagKeys`
- `s3:RequestObjectTag/tag-key`

For information about using object tags to control access, including example permission policies, see Tagging and access control policies.

Using temporary credentials with Amazon S3

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Forward access sessions for Amazon S3

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

- FAS is used by Amazon S3 to make calls to AWS KMS to decrypt an object when SSE-KMS was used to encrypt it. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS).
- S3 Access Grants also uses FAS. After you create an access grant to your S3 data for a particular identity, the grantee requests a temporary credential from S3 Access Grants. S3 Access Grants obtains a temporary credential for the requester from AWS STS and vends the credential to the requester. For more information, see Request access to Amazon S3 data through S3 Access Grants.

Service roles for Amazon S3

Supports service roles: Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Amazon S3 functionality. Edit service roles only when Amazon S3 provides guidance to do so.

Service-linked roles for Amazon S3

Supports service-linked roles: Partial

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Amazon S3 supports service-linked roles for Amazon S3 Storage Lens. For details about creating or managing Amazon S3 service-linked roles, see Using service-linked roles for Amazon S3 Storage Lens.

Amazon S3 Service as a Principal

Service name in the policy	S3 feature	More information
`s3.amazonaws.com`	S3 Replication	Setting up live replication overview
`s3.amazonaws.com`	S3 event notifications	Amazon S3 Event Notifications

How Amazon S3 authorizes a request

When Amazon S3 receives a request—for example, a bucket or an object operation—it first verifies that the requester has the necessary permissions. Amazon S3 evaluates all the relevant access policies, user policies, and resource-based policies (bucket policy, bucket access control list (ACL), and object ACL) in deciding whether to authorize the request.

> **Note**
>
> If the Amazon S3 permission check fails to find valid permissions, an Access Denied (403 Forbidden)permission denied error is returned. For more information, see Troubleshoot Access Denied (403 Forbidden) errors in Amazon S3.

To determine whether the requester has permission to perform the specific operation, Amazon S3 does the following, in order, when it receives a request:

1. Converts all the relevant access policies (user policy, bucket policy, and ACLs) at run time into a set of policies for evaluation.
2. Evaluates the resulting set of policies in the following steps. In each step, Amazon S3 evaluates a subset of policies in a specific context, based on the context authority.
   a. **User context** – In the user context, the parent account to which the user belongs is the context authority.

      Amazon S3 evaluates a subset of policies owned by the parent account. This subset includes the user policy that the parent attaches to the user. If the parent also owns the resource in the request (bucket or object), Amazon S3 also evaluates the corresponding resource policies (bucket policy, bucket ACL, and object ACL) at the same time.

      A user must have permission from the parent account to perform the operation.

      This step applies only if the request is made by a user in an AWS account. If the request is made by using the root user credentials of an AWS account, Amazon S3 skips this step.

   b. **Bucket context** – In the bucket context, Amazon S3 evaluates policies owned by the AWS account that owns the bucket.

      If the request is for a bucket operation, the requester must have permission from the bucket owner. If the request is for an object, Amazon S3 evaluates all the policies owned by the

bucket owner to check if the bucket owner has not explicitly denied access to the object. If there is an explicit deny set, Amazon S3 does not authorize the request.

c. **Object context** – If the request is for an object, Amazon S3 evaluates the subset of policies owned by the object owner.

Following are some example scenarios that illustrate how Amazon S3 authorizes a request.

Example– Requester is an IAM principal

If the requester is an IAM principal, Amazon S3 must determine if the parent AWS account to which the principal belongs has granted the principal necessary permission to perform the operation. In addition, if the request is for a bucket operation, such as a request to list the bucket content, Amazon S3 must verify that the bucket owner has granted permission for the requester to perform the operation. To perform a specific operation on a resource, an IAM principal needs permission from both the parent AWS account to which it belongs and the AWS account that owns the resource.

Example– Requester is an IAM principal – If the request is for an operation on an object that the bucket owner doesn't own

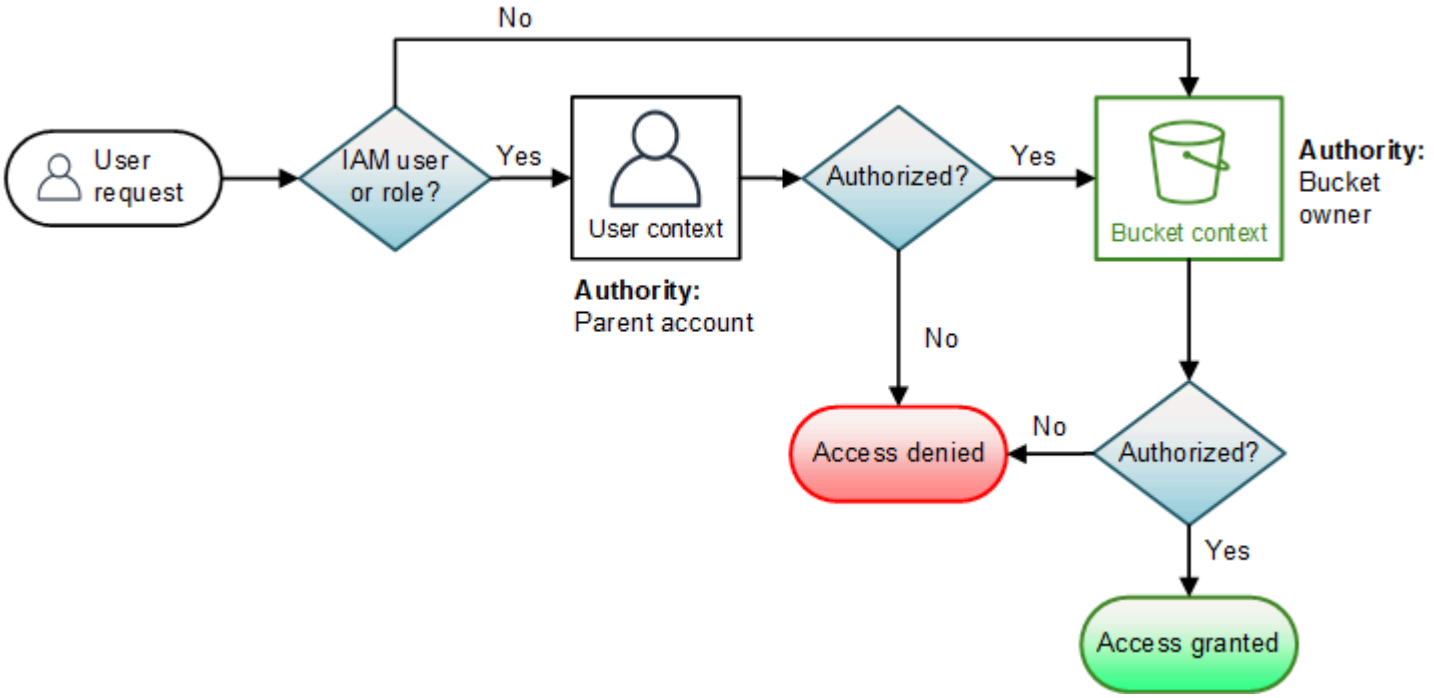
If the request is for an operation on an object that the bucket owner doesn't own, in addition to making sure the requester has permissions from the object owner, Amazon S3 must also check the bucket policy to ensure the bucket owner has not set explicit deny on the object. A bucket owner (who pays the bill) can explicitly deny access to objects in the bucket regardless of who owns it. The bucket owner can also delete any object in the bucket.

By default, when another AWS account uploads an object to your S3 general purpose bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through access control lists (ACLs). You can use Object Ownership to change this default behavior so that ACLs are disabled and you, as the bucket owner, automatically own every object in your general purpose bucket. As a result, access control for your data is based on policies, such as IAM user policies, S3 bucket policies, virtual private cloud (VPC) endpoint policies, and AWS Organizations service control policies (SCPs). For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

For more information about how Amazon S3 evaluates access policies to authorize or deny requests for bucket operations and object operations, see the following topics:

Topics

- How Amazon S3 authorizes a request for a bucket operation
- How Amazon S3 authorizes a request for an object operation

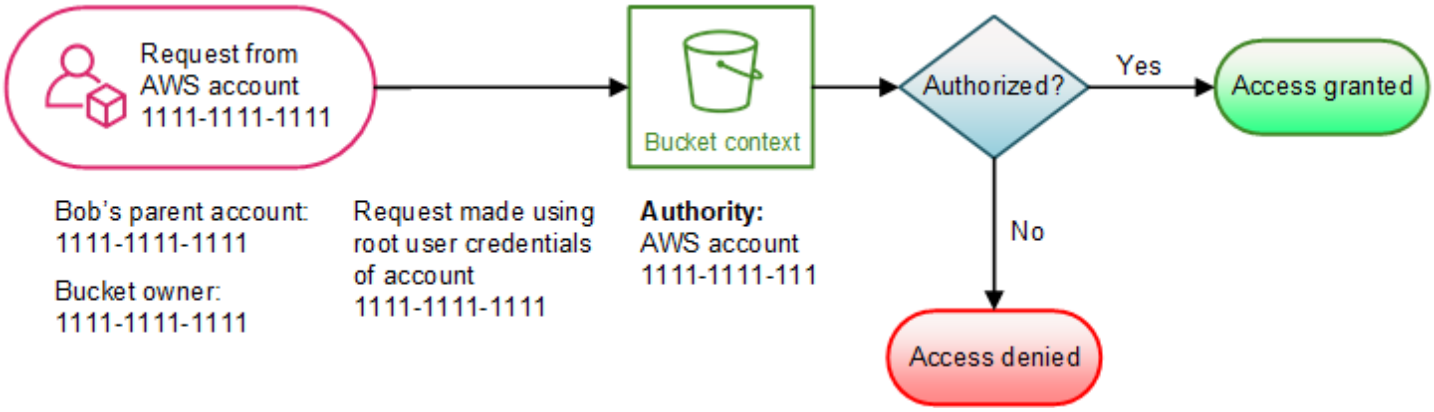


How Amazon S3 authorizes a request for a bucket operation

When Amazon S3 receives a request for a bucket operation, Amazon S3 converts all the relevant permissions into a set of policies to evaluate at run time. Relevant permissions include resource-based permissions (for example, bucket policies and bucket access control lists) and user policies if the request is from an IAM principal. Amazon S3 then evaluates the resulting set of policies in a series of steps according to a specific context—user context or bucket context:

1. **User context** – If the requester is an IAM principal, the principal must have permission from the parent AWS account to which it belongs. In this step, Amazon S3 evaluates a subset of policies owned by the parent account (also referred to as the context authority). This subset of policies includes the user policy that the parent account attaches to the principal. If the parent also owns the resource in the request (in this case, the bucket), Amazon S3 also evaluates the corresponding resource policies (bucket policy and bucket ACL) at the same time. Whenever a request for a bucket operation is made, the server access logs record the canonical ID of the requester. For more information, see Logging requests with server access logging.
2. **Bucket context** – The requester must have permissions from the bucket owner to perform a specific bucket operation. In this step, Amazon S3 evaluates a subset of policies owned by the AWS account that owns the bucket.

   The bucket owner can grant permission by using a bucket policy or bucket ACL. If the AWS account that owns the bucket is also the parent account of an IAM principal, then it can configure bucket permissions in a user policy.

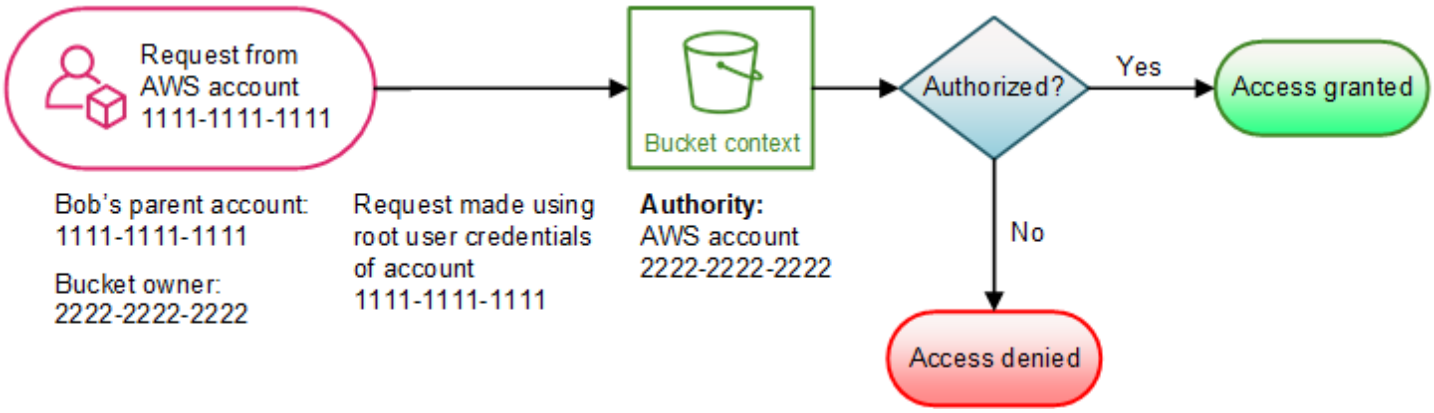


Context-based evaluation for bucket operation.

The following examples illustrate the evaluation logic.

Example 1: Bucket operation requested by bucket owner

In this example, the bucket owner sends a request for a bucket operation by using the root credentials of the AWS account.

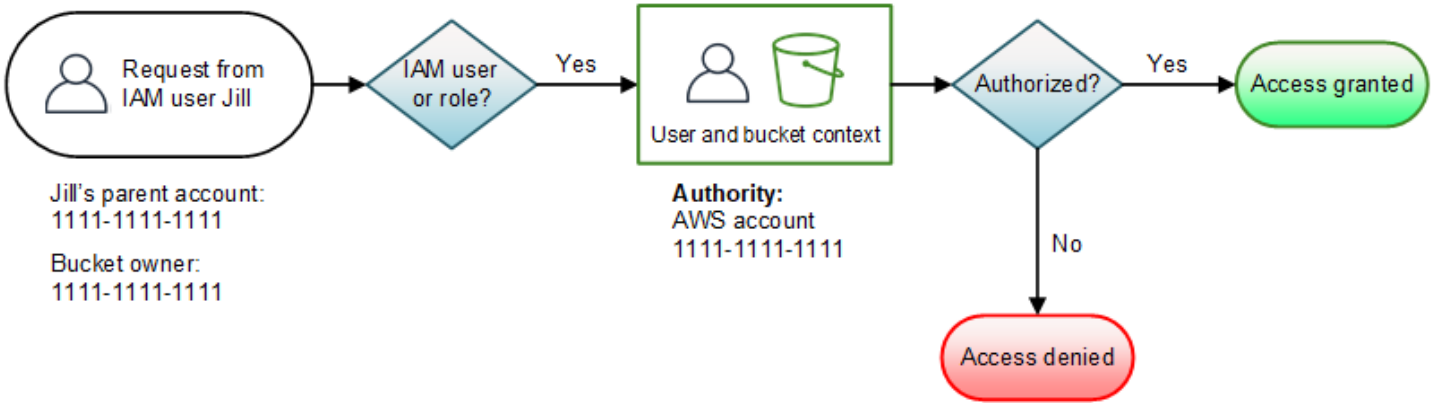


Amazon S3 performs the context evaluation as follows:

1. Because the request is made by using the root user credentials of an AWS account, the user context is not evaluated.
2. In the bucket context, Amazon S3 reviews the bucket policy to determine if the requester has permission to perform the operation. Amazon S3 authorizes the request.

Example 2: Bucket operation requested by an AWS account that is not the bucket owner

In this example, a request is made by using the root user credentials of AWS account 1111-1111-1111 for a bucket operation owned by AWS account 2222-2222-2222. No IAM users are involved in this request.

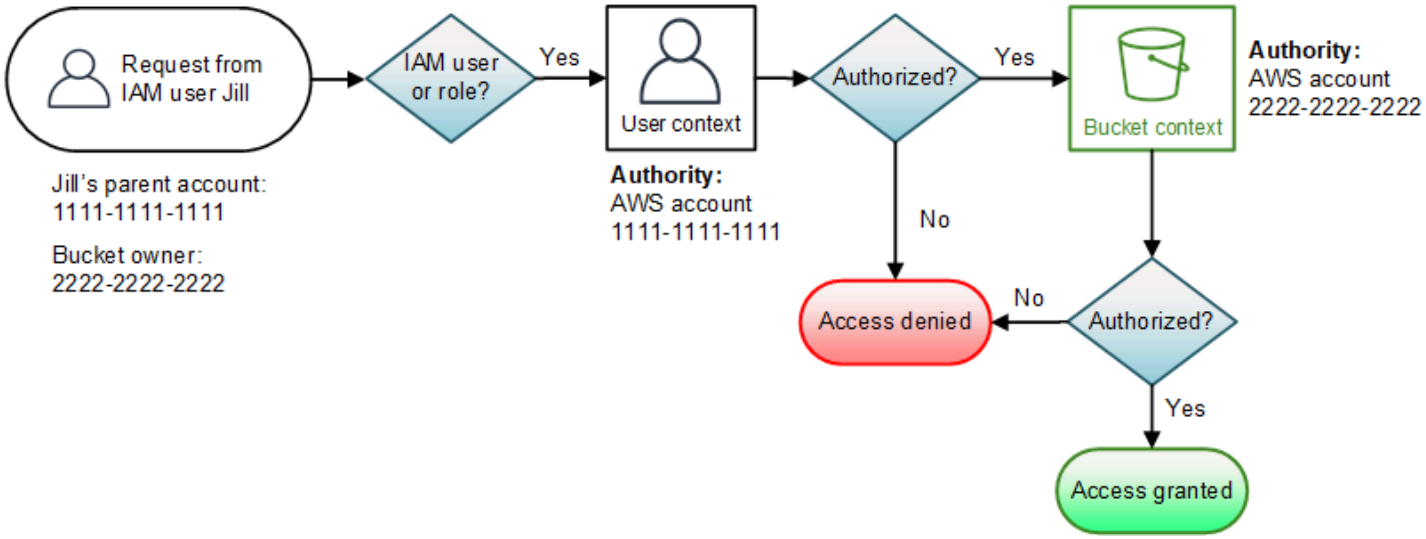


In this example, Amazon S3 evaluates the context as follows:

1. Because the request is made by using the root user credentials of an AWS account, the user context is not evaluated.
2. In the bucket context, Amazon S3 examines the bucket policy. If the bucket owner (AWS account 2222-2222-2222) has not authorized AWS account 1111-1111-1111 to perform the requested operation, Amazon S3 denies the request. Otherwise, Amazon S3 grants the request and performs the operation.

Example 3: Bucket operation requested by an IAM principal whose parent AWS account is also the bucket owner

In the example, the request is sent by Jill, an IAM user in AWS account 1111-1111-1111, which also owns the bucket.



Amazon S3 performs the following context evaluation:

1. Because the request is from an IAM principal, in the user context, Amazon S3 evaluates all policies that belong to the parent AWS account to determine if Jill has permission to perform the operation.

   In this example, parent AWS account 1111-1111-1111, to which the principal belongs, is also the bucket owner. As a result, in addition to the user policy, Amazon S3 also evaluates the bucket policy and bucket ACL in the same context because they belong to the same account.
2. Because Amazon S3 evaluated the bucket policy and bucket ACL as part of the user context, it does not evaluate the bucket context.

Example 4: Bucket operation requested by an IAM principal whose parent AWS account is not the bucket owner

In this example, the request is sent by Jill, an IAM user whose parent AWS account is 1111-1111-1111, but the bucket is owned by another AWS account, 2222-2222-2222.

Jill will need permissions from both the parent AWS account and the bucket owner. Amazon S3 evaluates the context as follows:

1. Because the request is from an IAM principal, Amazon S3 evaluates the user context by reviewing the policies authored by the account to verify that Jill has the necessary permissions. If Jill has permission, then Amazon S3 moves on to evaluate the bucket context. If Jill doesn't have permission, it denies the request.

2. In the bucket context, Amazon S3 verifies that bucket owner 2222-2222-2222 has granted Jill (or her parent AWS account) permission to perform the requested operation. If she has that permission, Amazon S3 grants the request and performs the operation. Otherwise, Amazon S3 denies the request.

How Amazon S3 authorizes a request for an object operation

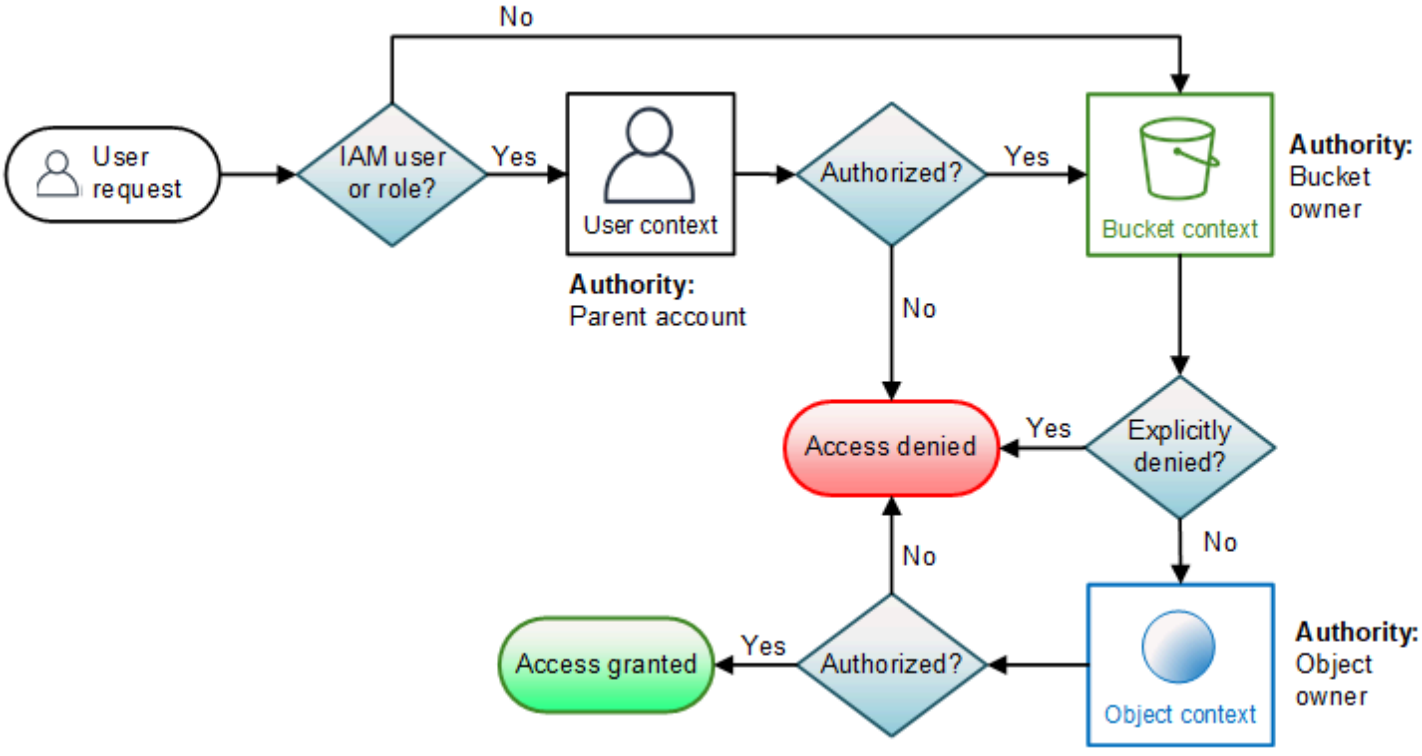
When Amazon S3 receives a request for an object operation, it converts all the relevant permissions — resource-based permissions (object access control list (ACL), bucket policy, bucket ACL) and IAM user policies—into a set of policies to be evaluated at run time. It then evaluates the resulting set of policies in a series of steps. In each step, it evaluates a subset of policies in three specific contexts—user context, bucket context, and object context:

1. **User context** – If the requester is an IAM principal, the principal must have permission from the parent AWS account to which it belongs. In this step, Amazon S3 evaluates a subset of policies owned by the parent account (also referred as the context authority). This subset of policies includes the user policy that the parent attaches to the principal. If the parent also owns the resource in the request (bucket or object), Amazon S3 evaluates the corresponding resource policies (bucket policy, bucket ACL, and object ACL) at the same time.

   > **Note**
   >
   > If the parent AWS account owns the resource (bucket or object), it can grant resource permissions to its IAM principal by using either the user policy or the resource policy.

2. **Bucket context** – In this context, Amazon S3 evaluates policies owned by the AWS account that owns the bucket.

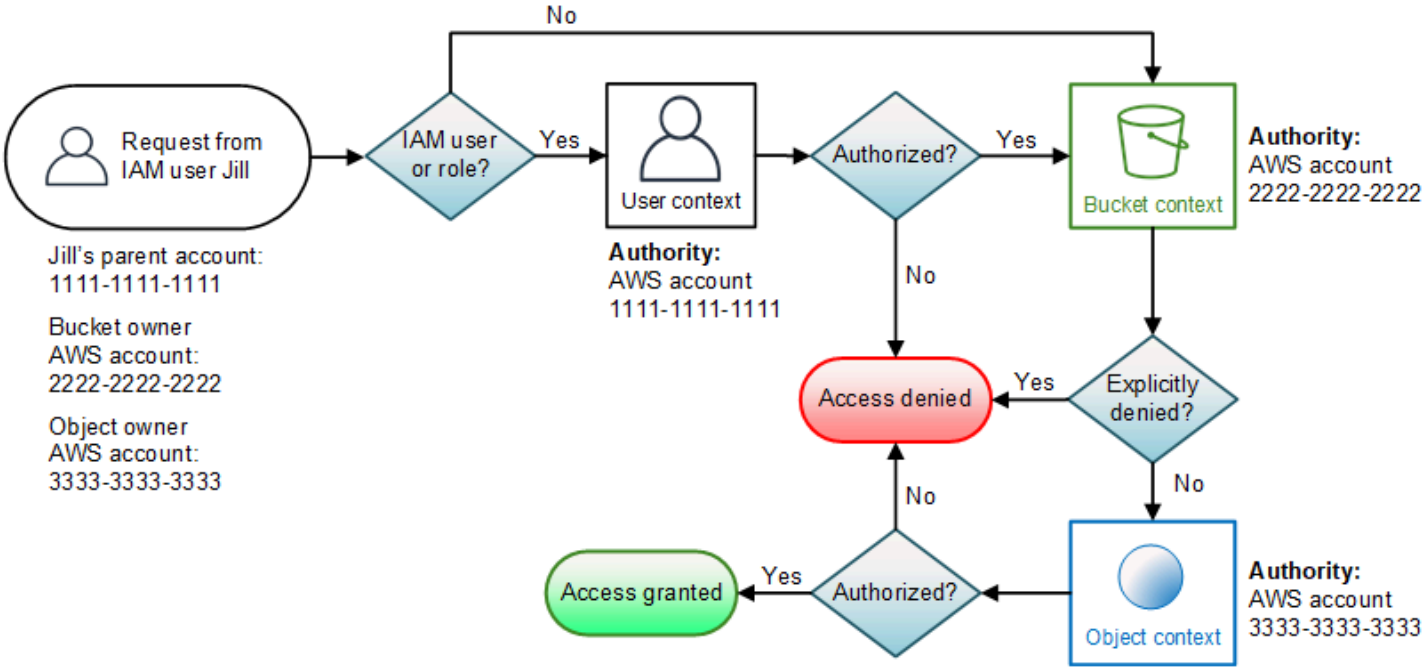
   If the AWS account that owns the object in the request is not same as the bucket owner, Amazon S3 checks the policies if the bucket owner has explicitly denied access to the object. If there is an explicit deny set on the object, Amazon S3 does not authorize the request.



3. **Object context** – The requester must have permissions from the object owner to perform a specific object operation. In this step, Amazon S3 evaluates the object ACL.

   > **Note**
   >
   > If bucket and object owners are the same, access to the object can be granted in the bucket policy, which is evaluated at the bucket context. If the owners are different, the

object owners must use an object ACL to grant permissions. If the AWS account that owns the object is also the parent account to which the IAM principal belongs, it can configure object permissions in a user policy, which is evaluated at the user context. For more information about using these access policy alternatives, see Walkthroughs that use policies to manage access to your Amazon S3 resources.



If you as the bucket owner want to own all the objects in your bucket and use bucket policies or policies based on IAMto manage access to these objects, you can apply the bucket owner enforced setting for Object Ownership. With this setting, you as the bucket owner automatically own and have full control over every object in your bucket. Bucket and object ACLs can't be edited and are no longer considered for access. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

The following is an illustration of the context-based evaluation for an object operation.

Example of an object operation request

In this example, IAM user Jill, whose parent AWS account is 1111-1111-1111, sends an object operation request (for example, `GetObject`) for an object owned by AWS account 3333-3333-3333 in a bucket owned by AWS account 2222-2222-2222.

Jill will need permission from the parent AWS account, the bucket owner, and the object owner. Amazon S3 evaluates the context as follows:

1. Because the request is from an IAM principal, Amazon S3 evaluates the user context to verify that the parent AWS account 1111-1111-1111 has given Jill permission to perform the requested operation. If she has that permission, Amazon S3 evaluates the bucket context. Otherwise, Amazon S3 denies the request.
2. In the bucket context, the bucket owner, AWS account 2222-2222-2222, is the context authority. Amazon S3 evaluates the bucket policy to determine if the bucket owner has explicitly denied Jill access to the object.
3. In the object context, the context authority is AWS account 3333-3333-3333, the object owner. Amazon S3 evaluates the object ACL to determine if Jill has permission to access the object. If she does, Amazon S3 authorizes the request.

Required permissions for Amazon S3 API operations

> **Note**
>
> This page is about Amazon S3 policy actions for general purpose buckets. To learn more about Amazon S3 policy actions for directory buckets, see Actions for directory buckets.

To perform an S3 API operation, you must have the right permissions. This page maps S3 API operations to the required permissions. To grant permissions to perform an S3 API operation, you must compose a valid policy (such as an S3 bucket policy or IAM identity-based policy), and specify corresponding actions in the `Action` element of the policy. These actions are called policy actions. Not every S3 API operation is represented by a single permission (a single policy action), and some permissions (some policy actions) are required for many different API operations.

When you compose policies, you must specify the `Resource` element based on the correct resource type required by the corresponding Amazon S3 policy actions. This page categorizes permissions to S3 API operations by the resource types. For more information about the resource types, see Resource types defined by Amazon S3 in the *Service Authorization Reference*. For a full list of Amazon S3 policy actions, resources, and condition keys for use in policies, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*. For a complete list of Amazon S3 API operations, see Amazon S3 API Actions in the *Amazon Simple Storage Service API Reference*.

For more information on how to address the HTTP `403 Forbidden` errors in S3, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3. For more information on the IAM features to use with S3, see How Amazon S3 works with IAM. For more information on S3 security best practices, see Security best practices for Amazon S3.

Bucket operations and permissions

Bucket operations are S3 API operations that operate on the bucket resource type. You must specify S3 policy actions for bucket operations in bucket policies or IAM identity-based policies.

In the policies, the `Resource` element must be the bucket Amazon Resource Name (ARN). For more information about the `Resource` element format and example policies, see Bucket operations.

Note

To grant permissions to bucket operations in access point policies, note the following:

- Permissions granted for bucket operations in an access point policy are effective only if the underlying bucket allows the same permissions. When you use an access point, you must delegate access control from the bucket to the access point or add the same permissions in the access point policy to the underlying bucket's policy.
- In access point policies that grant permissions to bucket operations, the `Resource` element must be the `accesspoint` ARN. For more information about the `Resource` element format and example policies, see Bucket operations in policies for access points for general purpose buckets. For more information about access point policies, see Configuring IAM policies for using access points.
- Not all bucket operations are supported by access points. For more information, see Access points compatibility with S3 operations.

The following is the mapping of bucket operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateBucket	(Required) `s3:CreateBucket`	Required to create a new s3 bucket.
	(Conditionally required) `s3:PutBucketAcl`	Required if you want to use access control list (ACL) to specify permissions on a bucket when you make a `CreateBucket` request.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `s3:PutBucketObjectLockConfiguration` , `s3:PutBucketVersioning`	Required if you want to enable Object Lock when you create a bucket.
	(Conditionally required) `s3:PutBucketOwnershipControls`	Required if you want to specify S3 Object Ownership when you create a bucket.

API operations	Policy actions	Description of policy actions
CreateBucketMetadataConfiguration (V2 API operation. The IAM policy action name is the same for the V1 and V2 API operations.)	(Required) `s3:CreateBucketMetadataTableConfiguration`, `s3tables:CreateTableBucket`, `s3tables:CreateNamespace`, `s3tables:CreateTable`, `s3tables:GetTable`, `s3tables:PutTablePolicy`, `s3tables:PutTableEncryption`, `kms:DescribeKey`	Required to create a metadata table configuration on a general purpose bucket. To create your AWS managed table bucket and the metadata tables that are specified in your metadata table configuration, you must have the specified `s3tables` permissions. If you want to encrypt your metadata tables with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you need additional permissions in your KMS key policy. For more information, see the section called "Permissions for metadata tables". If you also want to integrate your AWS managed table bucket with AWS analytics services so that you can query your metadata table, you need additional permissions. For more information, see Integrating Amazon S3 Tables with AWS analytics services.

API operations	Policy actions	Description of policy actions
CreateBucketMetadataTableConfiguration (V1 API operation)	(Required) `s3:CreateBucketMetadataTableConfiguration` , `s3tables:CreateNamespace` , `s3tables:CreateTable` , `s3tables:GetTable` , `s3tables:PutTablePolicy`	Required to create a metadata table configuration on a general purpose bucket. To create the metadata table in the table bucket that's specified in your metadata table configuration, you must have the specified `s3tables` permissions. If you want to encrypt your metadata tables with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you need additional permissions. For more information, see the section called “Permissions for metadata tables”. If you also want to integrate your table bucket with AWS analytics services so that you can query your metadata table, you need additional permissions. For more information, see Integrating Amazon S3 Tables with AWS analytics services.
DeleteBucket	(Required) `s3:DeleteBucket`	Required to delete an S3 bucket.

API operations	Policy actions	Description of policy actions
DeleteBucketAnalyticsConfiguration	(Required) `s3:PutAnalyticsConfiguration`	Required to delete an S3 analytics configuration from an S3 bucket.
DeleteBucketCors	(Required) `s3:PutBucketCORS`	Required to delete the cross-origin resource sharing (CORS) configuration for an bucket.
DeleteBucketEncryption	(Required) `s3:PutEncryptionConfiguration`	Required to reset the default encryption configuration for an S3 bucket as server-side encryption with Amazon S3 managed keys (SSE-S3).
DeleteBucketIntelligentTieringConfiguration	(Required) `s3:PutIntelligentTieringConfiguration`	Required to delete the existing S3 Intelligent-Tiering configuration from an S3 bucket.
DeleteBucketInventoryConfiguration	(Required) `s3:PutInventoryConfiguration`	Required to delete an S3 Inventory configuration from an S3 bucket.
DeleteBucketLifecycle	(Required) `s3:PutLifecycleConfiguration`	Required to delete the S3 Lifecycle configuration for an S3 bucket.
DeleteBucketMetadataConfiguration (V2 API operation. The IAM policy action name is the same for the V1 and V2 API operations.)	(Required) `s3:DeleteBucketMetadataTableConfiguration`	Required to delete a metadata table configuration from a general purpose bucket.

API operations	Policy actions	Description of policy actions
DeleteBucketMetadataTableConfiguration (V1 API operation)	(Required) `s3:DeleteBucketMetadataTableConfiguration`	Required to delete a metadata table configuration from a general purpose bucket.
DeleteBucketMetricsConfiguration	(Required) `s3:PutMetricsConfiguration`	Required to delete a metrics configuration for the Amazon CloudWatch request metrics from an S3 bucket.
DeleteBucketOwnershipControls	(Required) `s3:PutBucketOwnershipControls`	Required to remove the Object Ownership setting for an S3 bucket. After removal, the Object Ownership setting becomes `Object writer`.
DeleteBucketPolicy	(Required) `s3:DeleteBucketPolicy`	Required to delete the policy of an S3 bucket.
DeleteBucketReplication	(Required) `s3:PutReplicationConfiguration`	Required to delete the replication configuration of an S3 bucket.
DeleteBucketTagging	(Required) `s3:PutBucketTagging`	Required to delete tags from an S3 bucket.
DeleteBucketWebsite	(Required) `s3:DeleteBucketWebsite`	Required to remove the website configuration for an S3 bucket.
DeletePublicAccessBlock (Bucket-level)	(Required) `s3:PutBucketPublicAccessBlock`	Required to remove the block public access configuration for an S3 bucket.

API operations	Policy actions	Description of policy actions
GetBucketAccelerateConfiguration	(Required) `s3:GetAccelerateConfiguration`	Required to use the accelerate subresource to return the Amazon S3 Transfer Acceleration state of a bucket, which is either Enabled or Suspended.
GetBucketAcl	(Required) `s3:GetBucketAcl`	Required to return the access control list (ACL) of an S3 bucket.
GetBucketAnalyticsConfiguration	(Required) `s3:GetAnalyticsConfiguration`	Required to return an analytics configuration that's identified by the analytics configuration ID from an S3 bucket.
GetBucketCors	(Required) `s3:GetBucketCORS`	Required to return the cross-origin resource sharing (CORS) configuration for an S3 bucket.
GetBucketEncryption	(Required) `s3:GetEncryptionConfiguration`	Required to return the default encryption configuration for an S3 bucket.
GetBucketIntelligentTieringConfiguration	(Required) `s3:GetIntelligentTieringConfiguration`	Required to get the S3 Intelligent-Tiering configuration of an S3 bucket.
GetBucketInventoryConfiguration	(Required) `s3:GetInventoryConfiguration`	Required to return an inventory configuration that's identified by the inventory configuration ID from the bucket.

API operations	Policy actions	Description of policy actions
GetBucketLifecycle	(Required) `s3:GetLifecycleConfiguration`	Required to return the S3 Lifecycle configuration of the bucket.
GetBucketLocation	(Required) `s3:GetBucketLocation`	Required to return the AWS Region that an S3 bucket resides in.
GetBucketLogging	(Required) `s3:GetBucketLogging`	Required to return the logging status of an S3 bucket and the permissions that users have to view and modify that status.
GetBucketMetadataConfiguration (V2 API operation. The IAM policy action name is the same for the V1 and V2 API operations.)	(Required) `s3:GetBucketMetadataTableConfiguration`	Required to retrieve a metadata table configuration for a general purpose bucket.
GetBucketMetadataTableConfiguration (V1 API operation)	(Required) `s3:GetBucketMetadataTableConfiguration`	Required to retrieve a metadata table configuration for a general purpose bucket.
GetBucketMetricsConfiguration	(Required) `s3:GetMetricsConfiguration`	Required to get a metrics configuration that's specified by the metrics configuration ID from the bucket.
GetBucketNotificationConfiguration	(Required) `s3:GetBucketNotification`	Required to return the notification configuration of an S3 bucket.

API operations	Policy actions	Description of policy actions
GetBucketOwnershipControls	(Required) `s3:GetBucketOwnershipControls`	Required to retrieve the Object Ownership setting for an S3 bucket.
GetBucketPolicy	(Required) `s3:GetBucketPolicy`	Required to return the policy of an S3 bucket.
GetBucketPolicyStatus	(Required) `s3:GetBucketPolicyStatus`	Required to retrieve the policy status for an S3 bucket, indicating whether the bucket is public.
GetBucketReplication	(Required) `s3:GetReplicationConfiguration`	Required to return the replication configuration of an S3 bucket.
GetBucketRequestPayment	(Required) `s3:GetBucketRequestPayment`	Required to return the request payment configuration for an S3 bucket.
GetBucketVersioning	(Required) `s3:GetBucketVersioning`	Required to return the versioning state of an S3 bucket.
GetBucketTagging	(Required) `s3:GetBucketTagging`	Required to return the tag set that's associated with an S3 bucket.
GetBucketWebsite	(Required) `s3:GetBucketWebsite`	Required to return the website configuration for an S3 bucket.
GetObjectLockConfiguration	(Required) `s3:GetBucketObjectLockConfiguration`	Required to get the Object Lock configuration for an S3 bucket.

API operations	Policy actions	Description of policy actions
GetPublicAccessBlock (Bucket-level)	(Required) `s3:GetBucketPublicAccessBlock`	Required to retrieve the block public access configuration for an S3 bucket.
HeadBucket	(Required) `s3:ListBucket`	Required to determine if a bucket exists and if you have permission to access it.
ListBucketAnalyticsConfigurations	(Required) `s3:GetAnalyticsConfiguration`	Required to list the analytics configurations for an S3 bucket.
ListBucketIntelligentTieringConfigurations	(Required) `s3:GetIntelligentTieringConfiguration`	Required to list the S3 Intelligent-Tiering configurations of an S3 bucket.
ListBucketInventoryConfigurations	(Required) `s3:GetInventoryConfiguration`	Required to return a list of inventory configurations for an S3 bucket.
ListBucketMetricsConfigurations	(Required) `s3:GetMetricsConfiguration`	Required to list the metrics configurations for an S3 bucket.
ListObjects	(Required) `s3:ListBucket`	Required to list some or all (up to 1,000) of the objects in an S3 bucket.
	(Conditionally required) `s3:GetObjectAcl`	Required if you want to display object owner information.
ListObjectsV2	(Required) `s3:ListBucket`	Required to list some or all (up to 1,000) of the objects in an S3 bucket.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `s3:GetObjectAcl`	Required if you want to display object owner information.
ListObjectVersions	(Required) `s3:ListBucketVersions`	Required to get metadata about all the versions of objects in an S3 bucket.
PutBucketAccelerateConfiguration	(Required) `s3:PutAccelerateConfiguration`	Required to set the accelerate configuration of an existing bucket.
PutBucketAcl	(Required) `s3:PutBucketAcl`	Required to use access control lists (ACLs) to set the permissions on an existing bucket.
PutBucketAnalyticsConfiguration	(Required) `s3:PutAnalyticsConfiguration`	Required to set an analytics configuration for an S3 bucket.
PutBucketCors	(Required) `s3:PutBucketCORS`	Required to set the cross-origin resource sharing (CORS) configuration for an S3 bucket.
PutBucketEncryption	(Required) `s3:PutEncryptionConfiguration`	Required to configure the default encryption for an S3 bucket.
PutBucketIntelligentTieringConfiguration	(Required) `s3:PutIntelligentTieringConfiguration`	Required to put the S3 Intelligent-Tiering configuration to an S3 bucket.
PutBucketInventoryConfiguration	(Required) `s3:PutInventoryConfiguration`	Required to add an inventory configuration to an S3 bucket.

API operations	Policy actions	Description of policy actions
PutBucketLifecycle	(Required) `s3:PutLifecycleConfiguration`	Required to create a new S3 Lifecycle configuration or replace an existing lifecycle configuration for an S3 bucket.
PutBucketLogging	(Required) `s3:PutBucketLogging`	Required to set the logging parameters for an S3 bucket and specify permissions for who can view and modify the logging parameters.
PutBucketMetricsConfiguration	(Required) `s3:PutMetricsConfiguration`	Required to set or update a metrics configuration for the Amazon CloudWatch request metrics of an S3 bucket.
PutBucketNotificationConfiguration	(Required) `s3:PutBucketNotification`	Required to enable notifications of specified events for an S3 bucket.
PutBucketOwnershipControls	(Required) `s3:PutBucketOwnershipControls`	Required to create or modify the Object Ownership setting for an S3 bucket.
PutBucketPolicy	(Required) `s3:PutBucketPolicy`	Required to apply an S3 bucket policy to a bucket.
PutBucketReplication	(Required) `s3:PutReplicationConfiguration`	Required to create a new replication configuration or replace an existing one for an S3 bucket.
PutBucketRequestPayment	(Required) `s3:PutBucketRequestPayment`	Required to set the request payment configuration for a bucket.

API operations	Policy actions	Description of policy actions
PutBucketTagging	(Required) `s3:PutBucketTagging`	Required to add a set of tags to an S3 bucket.
PutBucketVersioning	(Required) `s3:PutBucketVersioning`	Required to set the versioning state of an S3 bucket.
PutBucketWebsite	(Required) `s3:PutBucketWebsite`	Required to configure a bucket as a website and set the configuration of the website.
PutObjectLockConfiguration	(Required) `s3:PutBucketObjectLockConfiguration`	Required to put Object Lock configuration on an S3 bucket.
PutPublicAccessBlock (Bucket-level)	(Required) `s3:PutBucketPublicAccessBlock`	Required to create or modify the block public access configuration for an S3 bucket.
UpdateBucketMetadataInventoryTableConfiguration	(Required) `s3:UpdateBucketMetadataInventoryTableConfiguration` , `s3tables:CreateTableBucket` , `s3tables:CreateNamespace` , `s3tables:CreateTable` , `s3tables:GetTable` , `s3tables:PutTablePolicy` , `s3tables:PutTableEncryption` , `kms:DescribeKey`	Required to enable or disable an inventory table for a metadata table configuration on a general purpose bucket. If you want to encrypt your inventory table with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you need additional permissions in your KMS key policy. For more information, see the section called “Permissions for metadata tables”.

API operations	Policy actions	Description of policy actions
UpdateBucketMetadataJournalTableConfiguration	(Required) s3:UpdateBucketMetadataJournalTableConfiguration	Required to enable or disable journal table record expiration for a metadata table configuration on a general purpose bucket.

Object operations and permissions

Object operations are S3 API operations that operate on the object resource type. You must specify S3 policy actions for object operations in resource-based policies (such as bucket policies, access point policies, Multi-Region Access Point policies, VPC endpoint policies) or IAM identity-based policies.

In the policies, the `Resource` element must be the object ARN. For more information about the `Resource` element format and example policies, see Object operations.

Note

- AWS KMS policy actions (`kms:GenerateDataKey` and `kms:Decrypt`) are only applicable for the AWS KMS resource type and must be specified in IAM identity-based policies and AWS KMS resource-based policies (AWS KMS key policies). You can't specify AWS KMS policy actions in S3 resource-based policies, such as S3 bucket policies.
- When you use access points to control access to object operations, you can use access point policies. To grant permissions to object operations in access point policies, note the following:
  - In access point policies that grant permissions to object operations, the `Resource` element must be the ARNs for objects accessed through an access point. For more information about the `Resource` element format and example policies, see Object operations in access point policies.
  - Not all object operations are supported by access points. For more information, see Access points compatibility with S3 operations.
- Not all object operations are supported by Multi-Region Access Points. For more information, see Multi-Region Access Point compatibility with S3 operations.

The following is the mapping of object operations and required policy actions.

API operations	Policy actions	Description of policy actions
AbortMultipartUpload	(Required) `s3:AbortMultipartUpload`	Required to abort a multipart upload.
CompleteMultipartUpload	(Required) `s3:PutObject`	Required to complete a multipart upload.
	(Conditionally required) `kms:Decrypt`	Required if you want to complete a multipart upload for an AWS KMS customer managed key encrypted object.
CopyObject	For source object:	For source object:
	(Required) Either `s3:GetObject` or `s3:GetObjectVersion`	• `s3:GetObject` – Required if you want to copy an object from the source bucket without specifying `versionId` in the request. • `s3:GetObjectVersion` – Required if you want to copy a specific version of an object from the source bucket by specifying `versionId` in the request.
	(Conditionally required) `kms:Decrypt`	Required if you want to copy an AWS KMS customer managed key encrypted object from the source bucket.

API operations	Policy actions	Description of policy actions
	For destination object:	For destination object:
	(Required) `s3:PutObject`	Required to put the copied object in the destination bucket.
	(Conditionally required) `s3:PutObjectAcl`	Required if you want to put the copied object with the object access control list (ACL) to the destination bucket when you make a `CopyObject` request.
	(Conditionally required) `s3:PutObjectTagging`	Required if you want to put the copied object with object tagging to the destination bucket when you make a `CopyObject` request.
	(Conditionally required) `kms:GenerateDataKey`	Required if you want to encrypt the copied object with an AWS KMS customer managed key and put it to the destination bucket.
	(Conditionally required) `s3:PutObjectRetention`	Required if you want to set an Object Lock retention configuration for the new object.
	(Conditionally required) `s3:PutObjectLegalHold`	Required if you want to place an Object Lock legal hold on the new object.
CreateMultipartUpload	(Required) `s3:PutObject`	Required to create multipart upload.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `s3:PutObjectAcl`	Required if you want to set the object access control list (ACL) permissions for the uploaded object.
	(Conditionally required) `s3:PutObjectTagging`	Required if you want to add object tagging(s) to the uploaded object.
	(Conditionally required) `kms:GenerateDataKey`	Required if you want to use an AWS KMS customer managed key to encrypt an object when you initiate a multipart upload.
	(Conditionally required) `s3:PutObjectRetention`	Required if you want to set an Object Lock retention configuration for the uploaded object.
	(Conditionally required) `s3:PutObjectLegalHold`	Required if you want to apply an Object Lock legal hold to the uploaded object.
DeleteObject	(Required) Either `s3:DeleteObject` or `s3:DeleteObjectVersion`	• `s3:DeleteObject` – Required if you want to remove an object without specifying `versionId` in the request. • `s3:DeleteObjectVersion` – Required if you want to remove a specific version of an object by specifying `versionId` in the request.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `s3:BypassGovernanceRetention`	Required if you want to delete an object that's protected by governance mode for Object Lock retention.
DeleteObjects	(Required) Either `s3:DeleteObject` or `s3:DeleteObjectVersion`	• `s3:DeleteObject` – Required if you want to remove an object without specifying `versionId` in the request. • `s3:DeleteObjectVersion` – Required if you want to remove a specific version of an object by specifying `versionId` in the request.
	(Conditionally required) `s3:BypassGovernanceRetention`	Required if you want to delete objects that are protected by governance mode for Object Lock retention.

API operations	Policy actions	Description of policy actions
DeleteObjectTagging	(Required) Either `s3:DeleteObjectTagging` or `s3:DeleteObjectVersionTagging`	• `s3:DeleteObjectTagging` – Required if you want to remove the entire tag set of an object without specifying `versionId` in the request. • `s3:DeleteObjectVersionTagging` – Required if you want to delete tags of a specific object version by specifying `versionId` in the request.
GetObject	(Required) Either `s3:GetObject` or `s3:GetObjectVersion`	• `s3:GetObject` – Required if you want to get an object without specifying `versionId` in the request. • `s3:GetObjectVersion` – Required if you want to get a specific version of an object by specifying `versionId` in the request.
	(Conditionally required) `kms:Decrypt`	Required if you want to get and decrypt an AWS KMS customer managed key encrypted object.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `s3:GetObjectTagging`	Required if you want to get the tag-set of an object when you make a `GetObject` request.
	(Conditionally required) `s3:GetObjectLegalHold`	Required if you want to get an object's current Object Lock legal hold status.
	(Conditionally required) `s3:GetObjectRetention`	Required if you want to retrieve the Object Lock retention settings for an object.
GetObjectAcl	(Required) Either `s3:GetObjectAcl` or `s3:GetObjectVersionAcl`	• `s3:GetObjectAcl` – Required if you want to get the access control list (ACL) of an object without specifying `versionId` in the request. • `s3:GetObjectVersionAcl` – Required if you want to get the access control list (ACL) of an object by specifying `versionId` in the request.

API operations	Policy actions	Description of policy actions
GetObjectAttributes	(Required) Either `s3:GetObject` or `s3:GetObjectVersion`	• `s3:GetObject` – Required if you want to retrieve attributes related to an object without specifying `versionId` in the request. • `s3:GetObjectVersion` – Required if you want to retrieve attributes related to a specific object version by specifying `versionId` in the request.
	(Conditionally required) `kms:Decrypt`	Required if you want to retrieve attributes related to an AWS KMS customer managed key encrypted object.
GetObjectLegalHold	(Required) `s3:GetObjectLegalHold`	Required to get an object's current Object Lock legal hold status.
GetObjectRetention	(Required) `s3:GetObjectRetention`	Required to retrieve the Object Lock retention settings for an object.

API operations	Policy actions	Description of policy actions
GetObjectTagging	(Required) Either `s3:GetObjectTagging` or `s3:GetObjectVersionTagging`	• `s3:GetObjectTagging` – Required if you want to get the tag set of an object without specifying `versionId` in the request. • `s3:GetObjectVersionTagging` – Required if you want to get the tags of a specific object version by specifying `versionId` in the request.
GetObjectTorrent	(Required) `s3:GetObject`	Required to return torrent files of an object.
HeadObject	(Required) `s3:GetObject`	Required to retrieve metadata from an object without returning the object itself.
	(Conditionally required) `s3:GetObjectLegalHold`	Required if you want to get an object's current Object Lock legal hold status.
	(Conditionally required) `s3:GetObjectRetention`	Required if you want to retrieve the Object Lock retention settings for an object.
ListMultipartUploads	(Required) `s3:ListBucketMultipartUploads`	Required to list in-progress multipart uploads in a bucket.
ListParts	(Required) `s3:ListMultipartUploadParts`	Required to list the parts that have been uploaded for a specific multipart upload.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `kms:Decrypt`	Required if you want to list parts of an AWS KMS customer managed key encrypted multipart upload.
PutObject	(Required) `s3:PutObject`	Required to put an object.
	(Conditionally required) `s3:PutObjectAcl`	Required if you want to put the object access control list (ACL) when you make a `PutObject` request.
	(Conditionally required) `s3:PutObjectTagging`	Required if you want to put object tagging when you make a `PutObject` request.
	(Conditionally required) `kms:GenerateDataKey`	Required if you want to encrypt an object with an AWS KMS customer managed key.
	(Conditionally required) `s3:PutObjectRetention`	Required if you want to set an Object Lock retention configuration on an object.
	(Conditionally required) `s3:PutObjectLegalHold`	Required if you want to apply an Object Lock legal hold configuration to a specified object.

API operations	Policy actions	Description of policy actions
PutObjectAcl	(Required) Either `s3:PutObjectAcl` or `s3:PutObjectVersionAcl`	• `s3:PutObjectAcl` – Required if you want to set the access control list (ACL) permissions for a new or existing object without specifying `versionId` in the request. • `s3:PutObjectVersionAcl` – Required if you want to set the access control list (ACL) permissions for a new or existing object by specifying `versionId` in the request.
PutObjectLegalHold	(Required) `s3:PutObjectLegalHold`	Required to apply an Object Lock legal hold configuration to an object.
PutObjectRetention	(Required) `s3:PutObjectRetention`	Required to apply an Object Lock retention configuration to an object.
	(Conditionally required) `s3:BypassGovernanceRetention`	Required if you want to bypass the governance mode of an Object Lock retention configuration.

API operations	Policy actions	Description of policy actions
PutObjectTagging	(Required) Either `s3:PutObjectTagging` or `s3:PutObjectVersionTagging`	• `s3:PutObjectTagging` – Required if you want to set the supplied tag set to an object that already exists in a bucket without specifying `versionId` in the request. • `s3:PutObjectVersionTagging` – Required if you want to set the supplied tag set to an object that already exists in a bucket by specifying `versionId` in the request.
RestoreObject	(Required) `s3:RestoreObject`	Required to restore a copy of an archived object.
SelectObjectContent	(Required) `s3:GetObject`	Required to filter the contents of an S3 object based on a simple structured query language (SQL) statement.
	(Conditionally required) `kms:Decrypt`	Required if you want to filter the contents of an S3 object that's encrypted with an AWS KMS customer managed key.

API operations	Policy actions	Description of policy actions
UpdateObjectEncryption	(Required) `s3:UpdateObjectEncryption` , `kms:Encrypt` , `kms:Decrypt` , `kms:GenerateDataKey` , `kms:ReEncrypt*`	Required if you want to change encrypted objects between server-side encryption with Amazon S3 managed encryption (SSE-S3) and server-side encryption with AWS Key Management Service (AWS KMS) encryption keys (SSE-KMS). You can also use the `UpdateObjectEncryption` operation to apply S3 Bucket Keys to reduce AWS KMS request costs or change the customer-managed KMS key that's used to encrypt your data so that you can comply with custom key-rotation standards.

API operations	Policy actions	Description of policy actions
	(Conditionally required) `organizations:DescribeAccount`	If you're using AWS Organizations, to use the `UpdateObjectEncryption` operation with customer-managed KMS keys from other AWS accounts within your organization, you must have the `organizations:DescribeAccount` permission. **Note** You must also request the ability to use AWS KMS keys owned by other member accounts within your organization by contacting AWS Support.
UploadPart	(Required) `s3:PutObject`	Required to upload a part in a multipart upload.
	(Conditionally required) `kms:GenerateDataKey`	Required if you want to put an upload part and encrypt it with an AWS KMS customer managed key.
UploadPartCopy	For source object:	For source object:

API operations	Policy actions	Description of policy actions
	(Required) Either `s3:GetObject` or `s3:GetObjectVersion`	• `s3:GetObject` – Required if you want to copy an object from the source bucket without specifying `versionId` in the request. • `s3:GetObjectVersion` – Required if you want to copy a specific version of an object from the source bucket by specifying `versionId` in the request.
	(Conditionally required) `kms:Decrypt`	Required if you want to copy an AWS KMS customer managed key encrypted object from the source bucket.
	For destination part:	For destination part:
	(Required) `s3:PutObject`	Required to upload a multipart upload part to the destination bucket.
	(Conditionally required) `kms:GenerateDataKey`	Required if you want to encrypt a part with an AWS KMS customer managed key when you upload the part to the destination bucket.

Access point for general purpose buckets operations and permissions

Access point operations are S3 API operations that operate on the `accesspoint` resource type. You must specify S3 policy actions for access point operations in IAM identity-based policies, not in bucket policies or access point policies.

In the policies, the `Resource` element must be the `accesspoint` ARN. For more information about the `Resource` element format and example policies, see Access point for general purpose bucket operations.

Note

If you want to use access points to control access to bucket or object operations, note the following:

- For using access points to control access to bucket operations, see Bucket operations in policies for access points for general purpose buckets.
- For using access points to control access to object operations, see Object operations in access point policies.
- For more information about how to configure access point policies, see Configuring IAM policies for using access points.

The following is the mapping of access point operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessPoint	(Required) `s3:CreateAccessPoint`	Required to create an access point that's associated with an S3 bucket.
DeleteAccessPoint	(Required) `s3:DeleteAccessPoint`	Required to delete an access point.
DeleteAccessPointPolicy	(Required) `s3:DeleteAccessPointPolicy`	Required to delete an access point policy.

API operations	Policy actions	Description of policy actions
GetAccessPointPolicy	(Required) `s3:GetAccessPointPolicy`	Required to retrieve an access point policy.
GetAccessPointPolicyStatus	(Required) `s3:GetAccessPointPolicyStatus`	Required to retrieve the information on whether the specified access point currently has a policy that allows public access.
PutAccessPointPolicy	(Required) `s3:PutAccessPointPolicy`	Required to put an access point policy.

Object Lambda Access Point operations and permissions

Object Lambda Access Point operations are S3 API operations that operate on the `objectlambdaaccesspoint` resource type. For more information about how to configure policies for Object Lambda Access Point operations, see Configuring IAM policies for Object Lambda Access Points.

The following is the mapping of Object Lambda Access Point operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessPointForObjectLambda	(Required) `s3:CreateAccessPointForObjectLambda`	Required to create an Object Lambda Access Point.
DeleteAccessPointForObjectLambda	(Required) `s3:DeleteAccessPointForObjectLambda`	Required to delete a specified Object Lambda Access Point.
DeleteAccessPointPolicyForObjectLambda	(Required) `s3:DeleteAccessPointPolicyForObjectLambda`	Required to delete the policy on a specified Object Lambda Access Point.

API operations	Policy actions	Description of policy actions
GetAccessPointConfigurationForObjectLambda	(Required) `s3:GetAccessPointConfigurationForObjectLambda`	Required to retrieve the configuration of the Object Lambda Access Point.
GetAccessPointForObjectLambda	(Required) `s3:GetAccessPointForObjectLambda`	Required to retrieve information about the Object Lambda Access Point.
GetAccessPointPolicyForObjectLambda	(Required) `s3:GetAccessPointPolicyForObjectLambda`	Required to return the access point policy that's associated with the specified Object Lambda Access Point.
GetAccessPointPolicyStatusForObjectLambda	(Required) `s3:GetAccessPointPolicyStatusForObjectLambda`	Required to return the policy status for a specific Object Lambda Access Point policy.
PutAccessPointConfigurationForObjectLambda	(Required) `s3:PutAccessPointConfigurationForObjectLambda`	Required to set the configuration of the Object Lambda Access Point.
PutAccessPointPolicyForObjectLambda	(Required) `s3:PutAccessPointPolicyForObjectLambda`	Required to associate an access policy with a specified Object Lambda Access Point.

Multi-Region Access Point operations and permissions

Multi-Region Access Point operations are S3 API operations that operate on the `multiregionaccesspoint` resource type. For more information about how to configure policies for Multi-Region Access Point operations, see Multi-Region Access Point policy examples.

The following is the mapping of Multi-Region Access Point operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateMultiRegionAccessPoint	(Required) `s3:CreateMultiRegionAccessPoint`	Required to create a Multi-Region Access Point and associate it with S3 buckets.
DeleteMultiRegionAccessPoint	(Required) `s3:DeleteMultiRegionAccessPoint`	Required to delete a Multi-Region Access Point.
DescribeMultiRegionAccessPointOperation	(Required) `s3:DescribeMultiRegionAccessPointOperation`	Required to retrieve the status of an asynchronous request to manage a Multi-Region Access Point.
GetMultiRegionAccessPoint	(Required) `s3:GetMultiRegionAccessPoint`	Required to return configuration information about the specified Multi-Region Access Point.
GetMultiRegionAccessPointPolicy	(Required) `s3:GetMultiRegionAccessPointPolicy`	Required to return the access control policy of the specified Multi-Region Access Point.
GetMultiRegionAccessPointPolicyStatus	(Required) `s3:GetMultiRegionAccessPointPolicyStatus`	Required to return the policy status for a specific Multi-Region Access Point about whether the specified Multi-Region Access Point has an access control policy that allows public access.
GetMultiRegionAccessPointRoutes	(Required) `s3:GetMultiRegionAccessPointRoutes`	Required to return the routing configuration for a Multi-Region Access Point.

API operations	Policy actions	Description of policy actions
PutMultiRegionAccessPointPolicy	(Required) `s3:PutMultiRegionAccessPointPolicy`	Required to update the access control policy of the specified Multi-Region Access Point.
SubmitMultiRegionAccessPointRoutes	(Required) `s3:SubmitMultiRegionAccessPointRoutes`	Required to submit an updated route configuration for a Multi-Region Access Point.

Batch job operations and permissions

(Batch Operations) job operations are S3 API operations that operate on the `job` resource type. You must specify S3 policy actions for job operations in IAM identity-based policies, not in bucket policies.

In the policies, the `Resource` element must be the `job` ARN. For more information about the `Resource` element format and example policies, see Batch job operations.

The following is the mapping of batch job operations and required policy actions.

API operations	Policy actions	Description of policy actions
DeleteJobTagging	(Required) `s3:DeleteJobTagging`	Required to remove tags from an existing S3 Batch Operations job.
DescribeJob	(Required) `s3:DescribeJob`	Required to retrieve the configuration parameters and status for a Batch Operations job.
GetJobTagging	(Required) `s3:GetJobTagging`	Required to return the tag set of an existing S3 Batch Operations job.

API operations	Policy actions	Description of policy actions
PutJobTagging	(Required) `s3:PutJobTagging`	Required to put or replace tags on an existing S3 Batch Operations job.
UpdateJobPriority	(Required) `s3:UpdateJobPriority`	Required to update the priority of an existing job.
UpdateJobStatus	(Required) `s3:UpdateJobStatus`	Required to update the status for the specified job.

S3 Storage Lens configuration operations and permissions

S3 Storage Lens configuration operations are S3 API operations that operate on the `storagelensconfiguration` resource type. For more information about how to configure S3 Storage Lens configuration operations, see Setting Amazon S3 Storage Lens permissions.

The following is the mapping of S3 Storage Lens configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
DeleteStorageLensConfiguration	(Required) `s3:DeleteStorageLensConfiguration`	Required to delete the S3 Storage Lens configuration.
DeleteStorageLensConfigurationTagging	(Required) `s3:DeleteStorageLensConfigurationTagging`	Required to delete the S3 Storage Lens configuration tags.
GetStorageLensConfiguration	(Required) `s3:GetStorageLensConfiguration`	Required to get the S3 Storage Lens configuration.
GetStorageLensConfigurationTagging	(Required) `s3:GetStorageLensConfigurationTagging`	Required to get the tags of S3 Storage Lens configuration.

API operations	Policy actions	Description of policy actions
PutStorageLensConfigurationTagging	(Required) `s3:PutStorageLensConfigurationTagging`	Required to put or replace tags on an existing S3 Storage Lens configuration.

S3 Storage Lens groups operations and permissions

S3 Storage Lens groups operations are S3 API operations that operate on the `storagelensgroup` resource type. For more information about how to configure S3 Storage Lens groups permissions, see Storage Lens groups permissions.

The following is the mapping of S3 Storage Lens groups operations and required policy actions.

API operations	Policy actions	Description of policy actions
DeleteStorageLensGroup	(Required) `s3:DeleteStorageLensGroup`	Required to delete an existing S3 Storage Lens group.
GetStorageLensGroup	(Required) `s3:GetStorageLensGroup`	Required to retrieve the S3 Storage Lens group configuration details.
UpdateStorageLensGroup	(Required) `s3:UpdateStorageLensGroup`	Required to update the existing S3 Storage Lens group.
CreateStorageLensGroup	(Required) `s3:CreateStorageLensGroup`	Required to create a new Storage Lens group.
CreateStorageLensGroup, TagResource	(Required) `s3:CreateStorageLensGroup` , `s3:TagResource`	Required to create a new Storage Lens group with tags.
ListStorageLensGroups	(Required) `s3:ListStorageLensGroups`	Required to list all Storage Lens groups in your home Region.

API operations	Policy actions	Description of policy actions
ListTagsForResource	(Required) `s3:ListTagsForResource`	Required to list the tags that were added to your Storage Lens group.
TagResource	(Required) `s3:TagResource`	Required to add or update a Storage Lens group tag for an existing Storage Lens group.
UntagResource	(Required) `s3:UntagResource`	Required to delete a tag from a Storage Lens group.

S3 Access Grants instance operations and permissions

S3 Access Grants instance operations are S3 API operations that operate on the `accessgrantsinstance` resource type. An S3 Access Grants instance is a logical container for your access grants. For more information on working with S3 Access Grants instances, see Working with S3 Access Grants instances.

The following is the mapping of the S3 Access Grants instance configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
AssociateAccessGrantsIdentityCenter	(Required) `s3:AssociateAccessGrantsIdentityCenter`	Required to associate an AWS IAM Identity Center instance with your S3 Access Grants instance, thus enabling you to create access grants for users and groups in your corporate identity directory . You must also have the following permissions: `sso:CreateApplication` , `sso:PutApplicationGrant` , and

API operations	Policy actions	Description of policy actions
		`sso:PutApplicationAuthenticationMethod` .
CreateAccessGrantsInstance	(Required) `s3:CreateAccessGrantsInstance`	Required to create an S3 Access Grants instance (`accessgrantsinstance` resource) which is a container for your individual access grants. To associate an AWS IAM Identity Center instance with your S3 Access Grants instance, you must also have the `sso:DescribeInstance` , `sso:CreateApplication` , `sso:PutApplicationGrant` , and `sso:PutApplicationAuthenticationMethod` permissions.
DeleteAccessGrantsInstance	(Required) `s3:DeleteAccessGrantsInstance`	Required to delete an S3 Access Grants instance (`accessgrantsinstance` resource) from an AWS Region in your account.
DeleteAccessGrantsInstanceResourcePolicy	(Required) `s3:DeleteAccessGrantsInstanceResourcePolicy`	Required to delete a resource policy for your S3 Access Grants instance.

API operations	Policy actions	Description of policy actions
DissociateAccessGrantsIdentityCenter	(Required) `s3:DissociateAccessGrantsIdentityCenter`	Required to disassociate an AWS IAM Identity Center instance from your S3 Access Grants instance. You must also have the following permissions: `sso:DeleteApplication`
GetAccessGrantsInstance	(Required) `s3:GetAccessGrantsInstance`	Required to retrieve the S3 Access Grants instance for an AWS Region in your account.
GetAccessGrantsInstanceForPrefix	(Required) `s3:GetAccessGrantsInstanceForPrefix`	Required to retrieve the S3 Access Grants instance that contains a particular prefix.
GetAccessGrantsInstanceResourcePolicy	(Required) `s3:GetAccessGrantsInstanceResourcePolicy`	Required to return the resource policy of your S3 Access Grants instance.
ListAccessGrantsInstances	(Required) `s3:ListAccessGrantsInstances`	Required to return a list of the S3 Access Grants instances in your account.
PutAccessGrantsInstanceResourcePolicy	(Required) `s3:PutAccessGrantsInstanceResourcePolicy`	Required to update the resource policy of the S3 Access Grants instance.

S3 Access Grants location operations and permissions

S3 Access Grants location operations are S3 API operations that operate on the `accessgrantslocation` resource type. For more information on working with S3 Access Grants locations, see Working with S3 Access Grants locations.

The following is the mapping of the S3 Access Grants location configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessGrantsLocation	(Required) `s3:CreateAccessGrantsLocation`	Required to register a location in your S3 Access Grants instance (create an `accessgrantslocation` resource). You must also have the following permission for the specified IAM role: `iam:PassRole`
DeleteAccessGrantsLocation	(Required) `s3:DeleteAccessGrantsLocation`	Required to remove a registered location from your S3 Access Grants instance.
GetAccessGrantsLocation	(Required) `s3:GetAccessGrantsLocation`	Required to retrieve the details of a particular location registered in your S3 Access Grants instance.
ListAccessGrantsLocations	(Required) `s3:ListAccessGrantsLocations`	Required to return a list of the locations registered in your S3 Access Grants instance.
UpdateAccessGrantsLocation	(Required) `s3:UpdateAccessGrantsLocation`	Required to update the IAM role of a registered location in your S3 Access Grants instance.

S3 Access Grants grant operations and permissions

S3 Access Grants grant operations are S3 API operations that operate on the `accessgrant` resource type. For more information on working with individual grants using S3 Access Grants, see Working with grants in S3 Access Grants.

The following is the mapping of the S3 Access Grants grant configuration operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateAccessGrant	(Required) `s3:CreateAccessGrant`	Required to create an individual grant (`accessgrant` resource) for a user or group in your S3 Access Grants instance. You must also have the following permissions: For any directory identity — `sso:DescribeInstance` and `sso:DescribeApplication` For directory users — `identitystore:DescribeUser`
DeleteAccessGrant	(Required) `s3:DeleteAccessGrant`	Required to delete an individual access grant (`accessgrant` resource) from your S3 Access Grants instance.
GetAccessGrant	(Required) `s3:GetAccessGrant`	Required to get the details about an individual access grant in your S3 Access Grants instance.

API operations	Policy actions	Description of policy actions
ListAccessGrants	(Required) `s3:ListAccessGrants`	Required to return a list of individual access grants in your S3 Access Grants instance.
ListCallerAccessGrants	(Required) `s3:ListCallerAccessGrants`	Required to list the access grants that grant the caller access to Amazon S3 data through S3 Access Grants.

Account operations and permissions

Account operations are S3 API operations that operate on the account level. Account isn't a resource type defined by Amazon S3. You must specify S3 policy actions for account operations in IAM identity-based policies, not in bucket policies.

In the policies, the `Resource` element must be `"*"`. For more information about example policies, see Account operations.

The following is the mapping of account operations and required policy actions.

API operations	Policy actions	Description of policy actions
CreateJob	(Required) `s3:CreateJob`	Required to create a new S3 Batch Operations job.
CreateStorageLensGroup	(Required) `s3:CreateStorageLensGroup`	Required to create a new S3 Storage Lens group and associate it with the specified AWS account ID.
	(Conditionally required) `s3:TagResource`	Required if you want to create an S3 Storage Lens group with AWS resource tags.

API operations	Policy actions	Description of policy actions
DeletePublicAccessBlock (Account-level)	(Required) `s3:PutAccountPublicAccessBlock`	Required to remove the block public access configuration from an AWS account.
GetAccessPoint	(Required) `s3:GetAccessPoint`	Required to retrieve configuration information about the specified access point.
GetAccessPointPolicy (Account-level)	(Required) `s3:GetAccountPublicAccessBlock`	Required to retrieve the block public access configuration for an AWS account.
ListAccessPoints	(Required) `s3:ListAccessPoints`	Required to list access points of an S3 bucket that are owned by an AWS account.
ListAccessPointsForObjectLambda	(Required) `s3:ListAccessPointsForObjectLambda`	Required to list the Object Lambda Access Points.
ListBuckets	(Required) `s3:ListAllMyBuckets`	Required to return a list of all buckets that are owned by the authenticated sender of the request.
ListJobs	(Required) `s3:ListJobs`	Required to list current jobs and jobs that have ended recently.
ListMultiRegionAccessPoints	(Required) `s3:ListMultiRegionAccessPoints`	Required to return a list of the Multi-Region Access Points that are currently associated with the specified AWS account.

API operations	Policy actions	Description of policy actions
ListStorageLensConfigurations	(Required) `s3:ListStorageLensConfigurations`	Required to get a list of S3 Storage Lens configurations for an AWS account.
ListStorageLensGroups	(Required) `s3:ListStorageLensGroups`	Required to list all the S3 Storage Lens groups in the specified home AWS Region.
PutPublicAccessBlock (Account-level)	(Required) `s3:PutAccountPublicAccessBlock`	Required to create or modify the block public access configuration for an AWS account.
PutStorageLensConfiguration	(Required) `s3:PutStorageLensConfiguration`	Required to put an S3 Storage Lens configuration.

Policies and permissions in Amazon S3

This page provides an overview of bucket and user policies in Amazon S3 and describes the basic elements of an AWS Identity and Access Management (IAM) policy. Each listed element links to more details about that element and examples of how to use it.

For a complete list of Amazon S3 actions, resources, and conditions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

In its most basic sense, a policy contains the following elements:

- Resource – The Amazon S3 bucket, object, access point, or job that the policy applies to. Use the Amazon Resource Name (ARN) of the bucket, object, access point, or job to identify the resource.

  An example for bucket-level operations:

  `"Resource": "arn:aws:s3:::bucket_name"`

Examples for object-level operations:

- "Resource": "arn:aws:s3:::*bucket_name/**" for all objects in the bucket.
- "Resource": "arn:aws:s3:::*bucket_name/prefix/**" for objects under a certain prefix in the bucket.

For more information, see Policy resources for Amazon S3.

- Actions – For each resource, Amazon S3 supports a set of operations. You identify resource operations that you will allow (or deny) by using action keywords.

  For example, the s3:ListBucket permission allows the user to use the Amazon S3 ListObjectsV2 operation. (The s3:ListBucket permission is a case where the action name doesn't map directly to the operation name.) For more information about using Amazon S3 actions, see Policy actions for Amazon S3. For a complete list of Amazon S3 actions, see Actions in the *Amazon Simple Storage Service API Reference*.

- Effect – What the effect will be when the user requests the specific action—this can be either Allow or Deny.

  If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource. You might do this to make sure that a user can't access the resource, even if a different policy grants access. For more information, see IAM JSON Policy Elements: Effect in the *IAM User Guide*.

- Principal – The account or user who is allowed access to the actions and resources in the statement. In a bucket policy, the principal is the user, account, service, or other entity that is the recipient of this permission. For more information, see Principals for bucket policies.

- Condition – Conditions for when a policy is in effect. You can use AWS-wide keys and Amazon S3-specific keys to specify conditions in an Amazon S3 access policy. For more information, see Bucket policy examples using condition keys.

The following example bucket policy shows the Effect, Principal, Action, and Resource elements. This policy allows *Akua*, a user in account *123456789012*, s3:GetObject, s3:GetBucketLocation, and s3:ListBucket Amazon S3 permissions on the *amzn-s3-demo-bucket1* bucket.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "ExamplePolicy01",
    "Statement": [
        {
            "Sid": "ExampleStatement01",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Akua"
            },
            "Action": [
                "s3:GetObject",
                "s3:GetBucketLocation",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1/*",
                "arn:aws:s3:::amzn-s3-demo-bucket1"
            ]
        }
    ]
}
```

For complete policy language information, see Policies and permissions in IAM and IAM JSON policy reference in the *IAM User Guide*.

Permission delegation

If an AWS account owns a resource, it can grant those permissions to another AWS account. That account can then delegate those permissions, or a subset of them, to users in the account. This is referred to as *permission delegation*. But an account that receives permissions from another account can't delegate permission cross-account to another AWS account.

Amazon S3 bucket and object ownership

Buckets and objects are Amazon S3 resources. By default, only the resource owner can access these resources. The resource owner refers to the AWS account that creates the resource. For example:

- The AWS account that you use to create buckets and upload objects owns those resources.

- If you upload an object using AWS Identity and Access Management (IAM) user or role credentials, the AWS account that the user or role belongs to owns the object.
- A bucket owner can grant cross-account permissions to another AWS account (or users in another account) to upload objects. In this case, the AWS account that uploads objects owns those objects. The bucket owner doesn't have permissions on the objects that other accounts own, with the following exceptions:
  - The bucket owner pays the bills. The bucket owner can deny access to any objects, or delete any objects in the bucket, regardless of who owns them.
  - The bucket owner can archive any objects or restore archived objects regardless of who owns them. Archival refers to the storage class used to store the objects. For more information, see Managing the lifecycle of objects.

Ownership and request authentication

All requests to a bucket are either authenticated or unauthenticated. Authenticated requests must include a signature value that authenticates the request sender, and unauthenticated requests do not. For more information about request authentication, see Making requests in the *Amazon S3 API Reference*.

A bucket owner can allow unauthenticated requests. For example, unauthenticated PutObject requests are allowed when a bucket has a public bucket policy, or when a bucket ACL grants `WRITE` or `FULL_CONTROL` access to the `All Users` group or the anonymous user specifically. For more information about public bucket policies and public access control lists (ACLs), see The meaning of "public".

All unauthenticated requests are made by the anonymous user. This user is represented in ACLs by the specific canonical user ID `65a011a29cdf8ec533ec3d1ccaae921c`. If an object is uploaded to a bucket through an unauthenticated request, the anonymous user owns the object. The default object ACL grants `FULL_CONTROL` to the anonymous user as the object's owner. Therefore, Amazon S3 allows unauthenticated requests to retrieve the object or modify its ACL.

To prevent objects from being modified by the anonymous user, we recommend that you do not implement bucket policies that allow anonymous public writes to your bucket or use ACLs that allow the anonymous user write access to your bucket. You can enforce this recommended behavior by using Amazon S3 Block Public Access.

For more information about blocking public access, see Blocking public access to your Amazon S3 storage. For more information about ACLs, see Access control list (ACL) overview.

Important

We recommend that you don't use the AWS account root user credentials to make authenticated requests. Instead, create an IAM role and grant that role full access. We refer to users with this role as *administrator users*. You can use credentials assigned to the administrator role, instead of AWS account root user credentials, to interact with AWS and perform tasks, such as create a bucket, create users, and grant permissions. For more information, see AWS security credentials and Security best practices in IAM in the *IAM User Guide*.

Bucket policies for Amazon S3

A bucket policy is a resource-based policy that you can use to grant access permissions to your Amazon S3 bucket and the objects in it. Only the bucket owner can associate a policy with a bucket. The permissions attached to the bucket apply to all of the objects in the bucket that are owned by the bucket owner. These permissions don't apply to objects that are owned by other AWS accounts.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. The bucket owner owns all the objects in the bucket and manages access to data exclusively using policies.

Bucket policies use JSON-based AWS Identity and Access Management (IAM) policy language. You can use bucket policies to add or deny permissions for the objects in a bucket. Bucket policies can allow or deny requests based on the elements in the policy. These elements include the requester, S3 actions, resources, and aspects or conditions of the request (such as the IP address that's used to make the request).

For example, you can create a bucket policy that does the following:

- Grants other accounts cross-account permissions to upload objects to your S3 bucket
- Makes sure that you, the bucket owner, has full control of the uploaded objects

For more information, see Examples of Amazon S3 bucket policies.

> **Important**
>
> You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

The topics in this section provide examples and show you how to add a bucket policy in the S3 console. For information about identity-based policies, see Identity-based policies for Amazon S3. For information about bucket policy language, see Policies and permissions in Amazon S3.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Topics

- Adding a bucket policy by using the Amazon S3 console
- Controlling access from VPC endpoints with bucket policies
- Examples of Amazon S3 bucket policies
- Bucket policy examples using condition keys

Adding a bucket policy by using the Amazon S3 console

You can use the AWS Policy Generator and the Amazon S3 console to add a new bucket policy or edit an existing bucket policy. A bucket policy is a resource-based AWS Identity and Access Management (IAM) policy. You add a bucket policy to a bucket to grant other AWS accounts or IAM users access permissions for the bucket and the objects in it. Object permissions apply only to the objects that the bucket owner creates. For more information about bucket policies, see Identity and Access Management for Amazon S3.

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices. To learn more about validating policies by using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

For guidance on troubleshooting errors with a policy, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3.

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the list of buckets, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.
6. On the **Edit bucket policy** page, do one of the following:

   - To see examples of bucket policies, choose **Policy examples**. Or see Examples of Amazon S3 bucket policies in the *Amazon S3 User Guide*.
   - To generate a policy automatically, or edit the JSON in the **Policy** section, choose **Policy generator**.

   If you choose **Policy generator**, the AWS Policy Generator opens in a new window.

   a. On the **AWS Policy Generator** page, for **Select Type of Policy**, choose **S3 Bucket Policy**.

   b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat this step for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the *IAM User Guide*.

   > **Note**
   >
   > For your convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

   c. After you finish adding statements, choose **Generate Policy**.

   d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.

7. In the **Policy** box, edit the existing policy or paste the bucket policy from the AWS Policy Generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

   > **Note**
   >
   > Bucket policies are limited to 20 KB in size.

8. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to create an account analyzer in IAM Access Analyzer. For more information, see Preview access in the *IAM User Guide*.
9. Choose **Save changes**, which returns you to the **Permissions** tab.

Controlling access from VPC endpoints with bucket policies

You can use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints or specific VPCs. This section contains example bucket policies that you can use to control Amazon S3 bucket access from VPC endpoints. To learn how to set up VPC endpoints, see VPC Endpoints in the *VPC User Guide*.

A VPC enables you to launch AWS resources into a virtual network that you define. A VPC endpoint enables you to create a private connection between your VPC and another AWS service. This private connection doesn't require access over the internet, through a virtual private network (VPN) connection, through a NAT instance, or through Direct Connect.

A VPC endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC endpoint routes requests to Amazon S3 and routes responses back to the VPC. VPC endpoints change only how requests are routed. Amazon S3 public endpoints and DNS names will continue to work with VPC endpoints. For important information about using VPC endpoints with Amazon S3, see Gateway endpoints and Gateway endpoints for Amazon S3 in the *VPC User Guide*.

VPC endpoints for Amazon S3 provide two ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint. For information about this type of access control, see Controlling access to VPC endpoints using endpoint policies in the *VPC User Guide*.
- You can control which VPCs or VPC endpoints have access to your buckets by using Amazon S3 bucket policies. For examples of this type of bucket policy access control, see the following topics on restricting access.

Topics

- Restricting access to a specific VPC endpoint
- Restricting access to a specific VPC
- Restricting access to an IPv6 VPC endpoint

> **Important**
>
> When applying the Amazon S3 bucket policies for VPC endpoints described in this section, you might block your access to the bucket unintentionally. Bucket permissions that are intended to specifically limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see How do I fix my bucket policy when it has the wrong VPC or VPC endpoint ID? in the *AWS Support Knowledge Center*.

Restricting access to a specific VPC endpoint

The following is an example of an Amazon S3 bucket policy that restricts access to a specific bucket, `amzn-s3-demo-bucket`, only from the VPC endpoint with the ID `vpce-0abcdef1234567890`. If the specified endpoint is not used, the policy denies all access to the bucket. The `aws:SourceVpce` condition specifies the endpoint. The `aws:SourceVpce` condition doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the VPC endpoint ID. For more information about using conditions in a policy, see Bucket policy examples using condition keys.

> **Important**
>
> - Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.

- This policy disables console access to the specified bucket because console requests don't originate from the specified VPC endpoint.

JSON

```
{
   "Version":"2012-10-17",
   "Id": "Policy1415115909152",
   "Statement": [
     {
       "Sid": "Access-to-specific-VPCE-only",
       "Principal": "*",
       "Action": "s3:*",
       "Effect": "Deny",
       "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"],
       "Condition": {
         "StringNotEquals": {
           "aws:SourceVpce": "vpce-0abcdef1234567890"
         }
       }
     }
   ]
}
```

Restricting access to a specific VPC

You can create a bucket policy that restricts access to a specific VPC by using the `aws:SourceVpc` condition. This is useful if you have multiple VPC endpoints configured in the same VPC, and you want to manage access to your Amazon S3 buckets for all of your endpoints. The following is an example of a policy that denies access to `amzn-s3-demo-bucket` and its objects from anyone outside VPC `vpc-1a2b3c4d`. If the specified VPC isn't used, the policy denies all access to the bucket. This statement doesn't grant access to the bucket. To grant access, you must add a separate `Allow` statement. The `vpc-1a2b3c4d` condition key doesn't require an ARN for the VPC resource, only the VPC ID.

Important

- Before using the following example policy, replace the VPC ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables console access to the specified bucket because console requests don't originate from the specified VPC.

JSON

```
{
   "Version":"2012-10-17",
   "Id": "Policy1415115909153",
   "Statement": [
     {
       "Sid": "Access-to-specific-VPC-only",
       "Principal": "*",
       "Action": "s3:*",
       "Effect": "Deny",
       "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"],
       "Condition": {
         "StringNotEquals": {
           "aws:SourceVpc": "vpc-1a2b3c4d"
         }
       }
     }
   ]
}
```

Restricting access to an IPv6 VPC endpoint

The following example policy denies all Amazon S3 (`s3:`) actions on the *`amzn-s3-demo-bucket`* bucket and its objects, unless the request originates from the specified VPC endpoint (`vpce-0a1b2c3d4e5f6g`) and the source IP address matches the provided IPv6 CIDR block.

```
{
   "Version": "2012-10-17",
   "Id": "Policy1415115909154",
```

```
   "Statement": [
     {
       "Sid": "AccessSpecificIPv6VPCEOnly",
       "Action": "s3:*",
       "Effect": "Deny",
       "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"],
       "Condition": {
         "StringNotEquals": {
           "aws:SourceVpce": "vpce-0a1b2c3d4e5f6g"
         },
        "NotIpAddress": {
          "aws:VpcSourceIp": "2001:db8::/32"
        }
       }
     }
   ]
}
```

For information on how to restrict access to your bucket based on specific IPs or VPCs, see How do I allow only specific VPC endpoints or IP addresses to access my Amazon S3 bucket? in the AWS re:Post Knowledge Center.

Examples of Amazon S3 bucket policies

With Amazon S3 bucket policies, you can secure access to objects in your buckets, so that only users with the appropriate permissions can access them. You can even prevent authenticated users without the appropriate permissions from accessing your Amazon S3 resources.

This section presents examples of typical use cases for bucket policies. These sample policies use *amzn-s3-demo-bucket* as the resource value. To test these policies, replace the *user input placeholders* with your own information (such as your bucket name).

To grant or deny permissions to a set of objects, you can use wildcard characters (*) in Amazon Resource Names (ARNs) and other values. For example, you can control access to groups of objects that begin with a common prefix or end with a specific extension, such as `.html`.

For more information about AWS Identity and Access Management (IAM) policy language, see Policies and permissions in Amazon S3.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

> **Note**
>
> When testing permissions by using the Amazon S3 console, you must grant additional permissions that the console requires—`s3:ListAllMyBuckets`, `s3:GetBucketLocation`, and `s3:ListBucket`. For an example walkthrough that grants permissions to users and tests those permissions by using the console, see Controlling access to a bucket with user policies.

Additional resources for creating bucket policies include the following:

- For a list of the IAM policy actions, resources, and condition keys that you can use when creating a bucket policy, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.
- For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.
- For guidance on creating your S3 policy, see Adding a bucket policy by using the Amazon S3 console.
- To troubleshoot errors with a policy, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3.

If you're having trouble adding or updating a policy, see Why do I get the error "Invalid principal in policy" when I try to update my Amazon S3 bucket policy? in the AWS re:Post Knowledge Center.

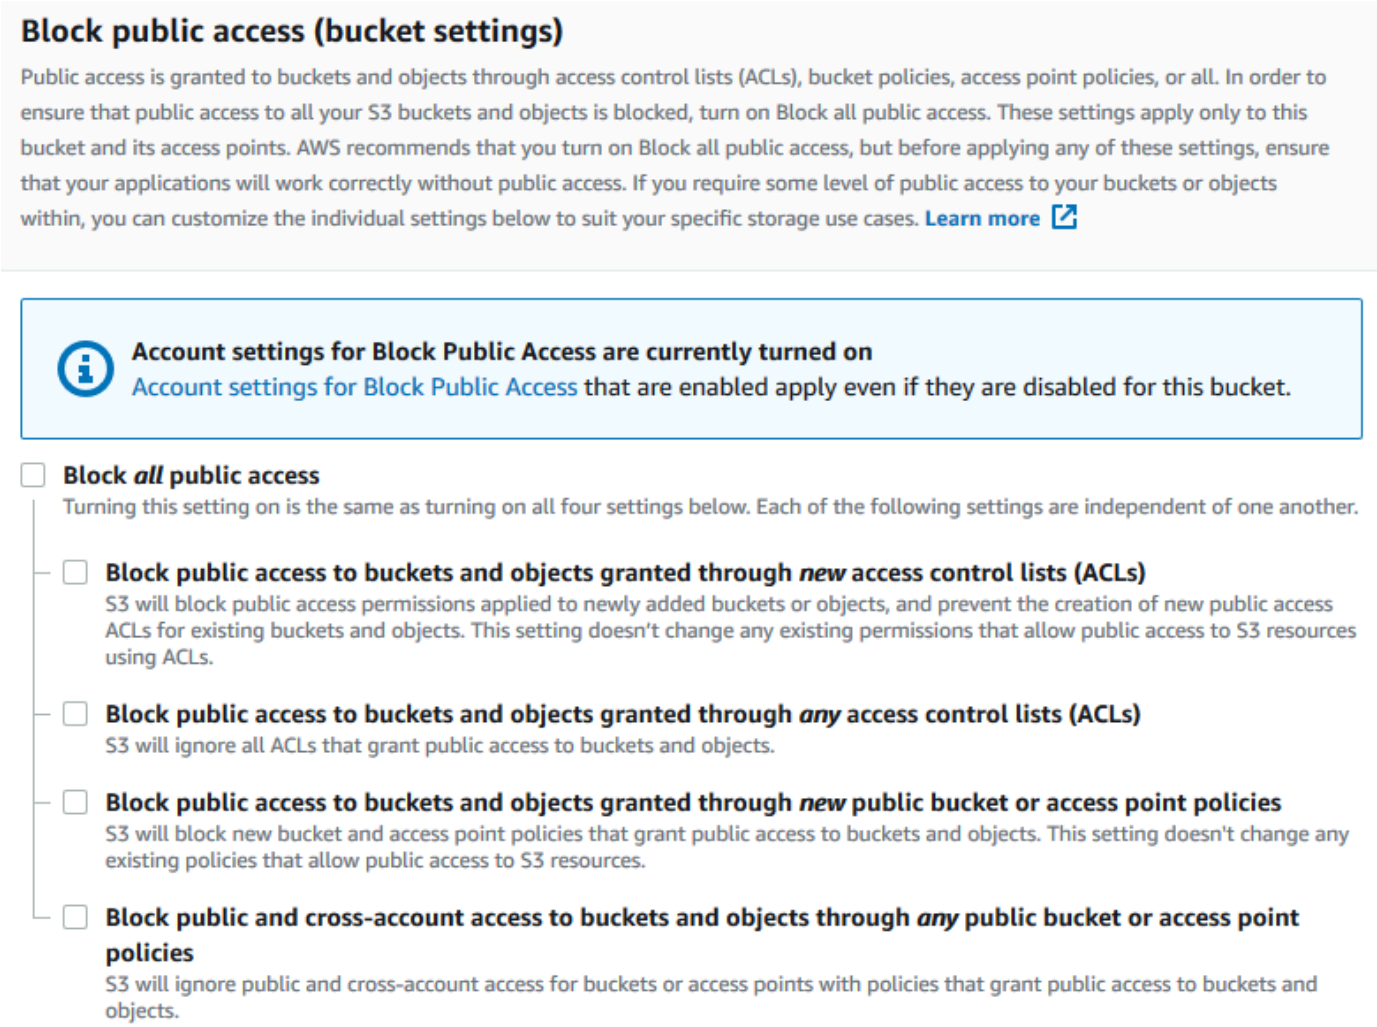
- Managing permissions for S3 Inventory, S3 analytics, and S3 Inventory reports
- Requiring MFA
- Preventing users from deleting objects



Granting read-only permission to a public anonymous user

You can use your policy settings to grant access to public anonymous users, which is useful if you're configuring your bucket as a static website. Granting access to public anonymous users requires you to disable the Block Public Access settings for your bucket. For more information about how to do this, and the policy required, see Setting permissions for website access. To learn how to set up more restrictive policies for the same purpose, see How can I grant public read access to some objects in my Amazon S3 bucket? in the AWS Knowledge Center.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Requiring encryption

You can require server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), as shown in the following examples.

Require SSE-KMS for all objects written to a bucket

The following example policy requires every object that is written to the bucket to be encrypted with server-side encryption using AWS Key Management Service (AWS KMS) keys (SSE-KMS). If the object isn't encrypted with SSE-KMS, the request is denied.

JSON

```
{
"Version":"2012-10-17",
"Id": "PutObjPolicy",
"Statement": [{
  "Sid": "DenyObjectsThatAreNotSSEKMS",
  "Principal": "*",
  "Effect": "Deny",
  "Action": "s3:PutObject",
  "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
  "Condition": {
    "Null": {
      "s3:x-amz-server-side-encryption-aws-kms-key-id": "true"
    }
  }
}]
}
```

Require SSE-KMS with a specific AWS KMS key for all objects written to a bucket

The following example policy denies any objects from being written to the bucket if they aren't encrypted with SSE-KMS by using a specific KMS key ID. Even if the objects are encrypted with SSE-KMS by using a per-request header or bucket default encryption, the objects can't be written to the bucket if they haven't been encrypted with the specified KMS key. Make sure to replace the KMS key ARN that's used in this example with your own KMS key ARN.

JSON

```
{
"Version":"2012-10-17",
"Id": "PutObjPolicy",
"Statement": [{
  "Sid": "DenyObjectsThatAreNotSSEKMSWithSpecificKey",
  "Principal": "*",
  "Effect": "Deny",
  "Action": "s3:PutObject",
  "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
  "Condition": {
    "ArnNotEqualsIfExists": {
```

```
      "s3:x-amz-server-side-encryption-aws-kms-key-id": "arn:aws:kms:us-
east-1:111122223333:key/01234567-89ab-cdef-0123-456789abcdef"
    }
  }
}]
}
```

Managing buckets using canned ACLs

Granting permissions to multiple accounts to upload objects or set object ACLs for public access

The following example policy grants the `s3:PutObject` and `s3:PutObjectAcl` permissions to multiple AWS accounts. Also, the example policy requires that any requests for these operations must include the `public-read` canned access control list (ACL). For more information, see Policy actions for Amazon S3 and Policy condition keys for Amazon S3.

> **Warning**
>
> The `public-read` canned ACL allows anyone in the world to view the objects in your bucket. Use caution when granting anonymous access to your Amazon S3 bucket or disabling block public access settings. When you grant anonymous access, anyone in the world can access your bucket. We recommend that you never grant anonymous access to your Amazon S3 bucket unless you specifically need to, such as with static website hosting. If you want to enable block public access settings for static website hosting, see Tutorial: Configuring a static website on Amazon S3.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AddPublicReadCannedAcl",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root",
                    "arn:aws:iam::444455556666:root"
```

```
                ]
            },
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": [
                        "public-read"
                    ]
                }
            }
        }
    ]
}
```

Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control

The following example shows how to allow another AWS account to upload objects to your bucket while ensuring that you have full control of the uploaded objects. This policy grants a specific AWS account (*111122223333*) the ability to upload objects only if that account includes the `bucket-owner-full-control` canned ACL on upload. The `StringEquals` condition in the policy specifies the `s3:x-amz-acl` condition key to express the canned ACL requirement. For more information, see Policy condition keys for Amazon S3.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
     {
       "Sid":"PolicyForAllowUploadWithACL",
       "Effect":"Allow",
       "Principal":{"AWS":"111122223333"},
       "Action":"s3:PutObject",
       "Resource":"arn:aws:s3:::amzn-s3-demo-bucket/*",
       "Condition": {
         "StringEquals": {"s3:x-amz-acl":"bucket-owner-full-control"}
```

```
        }
      }
   ]
}
```

Managing object access with object tagging

Allow a user to read only objects that have a specific tag key and value

The following permissions policy limits a user to only reading objects that have the `environment:production` tag key and value. This policy uses the `s3:ExistingObjectTag` condition key to specify the tag key and value.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Principal":{
            "AWS":"arn:aws:iam::111122223333:role/JohnDoe"
         },
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket/*",
         "Condition":{
            "StringEquals":{
               "s3:ExistingObjectTag/environment":"production"
            }
         }
      }
   ]
}
```

Restrict which object tag keys that users can add

The following example policy grants a user permission to perform the `s3:PutObjectTagging` action, which allows a user to add tags to an existing object. The condition uses the `s3:RequestObjectTagKeys` condition key to specify the allowed tag keys, such as `Owner` or `CreationDate`. For more information, see Creating a condition that tests multiple key values in the *IAM User Guide*.

The policy ensures that every tag key specified in the request is an authorized tag key. The `ForAnyValue` qualifier in the condition ensures that at least one of the specified keys must be present in the request.

JSON

```
{
   "Version":"2012-10-17",
  "Statement": [
    {"Principal":{"AWS":[
            "arn:aws:iam::111122223333:role/JohnDoe"
         ]
       },
 "Effect": "Allow",
      "Action": [
        "s3:PutObjectTagging"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ],
      "Condition": {"ForAnyValue:StringEquals": {"s3:RequestObjectTagKeys": [
            "Owner",
            "CreationDate"
          ]
        }
      }
    }
  ]
}
```

Require a specific tag key and value when allowing users to add object tags

The following example policy grants a user permission to perform the `s3:PutObjectTagging` action, which allows a user to add tags to an existing object. The condition requires the user to include a specific tag key (such as *`Project`*) with the value set to *`X`*.

JSON

```
{
   "Version":"2012-10-17",
  "Statement": [
    {"Principal":{"AWS":[
       "arn:aws:iam::111122223333:user/JohnDoe"
         ]
       },
      "Effect": "Allow",
      "Action": [
        "s3:PutObjectTagging"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ],
      "Condition": {"StringEquals": {"s3:RequestObjectTag/Project": "X"
        }
      }
    }
  ]
}
```

Allow a user to only add objects with a specific object tag key and value

The following example policy grants a user permission to perform the `s3:PutObject` action so that they can add objects to a bucket. However, the `Condition` statement restricts the tag keys and values that are allowed on the uploaded objects. In this example, the user can only add objects that have the specific tag key (*`Department`*) with the value set to *`Finance`* to the bucket.

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [{
        "Principal":{
            "AWS":[
                 "arn:aws:iam::111122223333:user/JohnDoe"
         ]
        },
        "Effect": "Allow",
        "Action": [
            "s3:PutObject"
        ],
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ],
        "Condition": {
            "StringEquals": {
                "s3:RequestObjectTag/Department": "Finance"
            }
        }
    }]
}
```

Managing object access by using global condition keys

Global condition keys are condition context keys with an `aws` prefix. AWS services can support global condition keys or service-specific keys that include the service prefix. You can use the `Condition` element of a JSON policy to compare the keys in a request with the key values that you specify in your policy.

Restrict access to only Amazon S3 server access log deliveries

In the following example bucket policy, the aws:SourceArn global condition key is used to compare the Amazon Resource Name (ARN) of the resource, making a service-to-service request with the ARN that is specified in the policy. The `aws:SourceArn` global condition key is used to prevent the Amazon S3 service from being used as a confused deputy during transactions between services. Only the Amazon S3 service is allowed to add objects to the Amazon S3 bucket.

This example bucket policy grants `s3:PutObject` permissions to only the logging service principal (`logging.s3.amazonaws.com`).

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowPutObjectS3ServerAccessLogsPolicy",
            "Principal": {
                "Service": "logging.s3.amazonaws.com"
            },
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket-logs/*",
            "Condition": {
                "StringEquals": {
                "aws:SourceAccount": "111122223333"
                },
                "ArnLike": {
                "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-bucket1"
                }
            }
        },
        {
            "Sid": "RestrictToS3ServerAccessLogs",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket-logs/*",
            "Condition": {
                "ForAllValues:StringNotEquals": {
                    "aws:PrincipalServiceNamesList": "logging.s3.amazonaws.com"
                }
            }
        }
    ]
}
```

Allow access to only your organization

If you want to restrict IAM-based access to a resource so that only principals from AWS accounts in your organization (including the AWS Organizations management account) can access it, you can use the `aws:PrincipalOrgID` global condition key.

Here's an example of a resource-based bucket policy that you can use to grant specific IAM principals in your organization direct access to your bucket. By adding the `aws:PrincipalOrgID` global condition key to your bucket policy, the principal account is now required to be in your organization to obtain access through this policy statement. Even if you accidentally specify an incorrect account when granting access, the `aws:PrincipalOrgID` global condition key acts as an additional safeguard. When this global key is used in an Allow statement, it ensures that only principals from accounts in the listed organization can obtain access through that statement.

> **Important**
>
> This Allow statement with a condition does not deny access granted through other mechanisms. If your bucket has ACLs enabled or other policies that grant access, principals outside your organization may still be able to access objects. To fully restrict access to only your organization, we recommend using this condition in a Deny statement (see example below), disabling ACLs by setting Object Ownership to "Bucket owner enforced", and enabling S3 Block Public Access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
        "Sid": "AllowGetObject",
        "Principal": {
            "AWS": "*"
        },
        "Effect": "Allow",
        "Action": "s3:GetObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
        "Condition": {
            "StringEquals": {
                "aws:PrincipalOrgID": ["o-aa111bb222"]
            }
```

```
        }
    }]
}
```

Deny access to principals outside your organization

For stronger protection, use a Deny statement with the `aws:PrincipalOrgID` condition. A Deny statement overrides any Allow, regardless of how access is granted. The following example denies all S3 actions to any principal that is not in your organization. This approach provides defense-in-depth even if ACLs or other policies would have inadvertently granted access.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyAccessFromOutsideOrg",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:*",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ],
            "Condition": {
                "StringNotEquals": {
                    "aws:PrincipalOrgID": "o-aa111bb222"
                }
            }
        }
    ]
}
```

Managing access based on HTTP or HTTPS requests

Restrict access to only HTTPS requests

If you want to prevent potential attackers from manipulating network traffic, you can use HTTPS (TLS) to only allow encrypted connections while restricting HTTP requests from accessing your bucket. To determine whether the request is HTTP or HTTPS, use the aws:SecureTransport global condition key in your S3 bucket policy. The `aws:SecureTransport` condition key checks whether a request was sent by using HTTP.

If a request returns `true`, then the request was sent through HTTPS. If the request returns `false`, then the request was sent through HTTP. You can then allow or deny access to your bucket based on the desired request scheme.

In the following example, the bucket policy explicitly denies HTTP requests.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
        "Sid": "RestrictToTLSRequestsOnly",
        "Action": "s3:*",
        "Effect": "Deny",
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket",
            "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ],
        "Condition": {
            "Bool": {
                "aws:SecureTransport": "false"
            }
        },
        "Principal": "*"
    }]
}
```

Restrict access to a specific HTTP referer

Suppose that you have a website with the domain name *www.example.com* or *example.com* with links to photos and videos stored in your bucket named *amzn-s3-demo-bucket*. By default, all Amazon S3 resources are private, so only the AWS account that created the resources can access them.

To allow read access to these objects from your website, you can add a bucket policy that allows the `s3:GetObject` permission with a condition that the `GET` request must originate from specific webpages. The following policy restricts requests by using the `StringLike` condition with the `aws:Referer` condition key.

Make sure that the browsers that you use include the HTTP `referer` header in the request.

> **Warning**
>
> We recommend that you use caution when using the `aws:Referer` condition key. It is dangerous to include a publicly known HTTP referer header value. Unauthorized parties can use modified or custom browsers to provide any `aws:Referer` value that they choose. Therefore, do not use `aws:Referer` to prevent unauthorized parties from making direct AWS requests.
>
> The `aws:Referer` condition key is offered only to allow customers to protect their digital content, such as content stored in Amazon S3, from being referenced on unauthorized third-party sites. For more information, see aws:Referer in the *IAM User Guide*.

Managing user access to specific folders

Grant users access to specific folders

Suppose that you're trying to grant users access to a specific folder. If the IAM user and the S3 bucket belong to the same AWS account, then you can use an IAM policy to grant the user access to a specific bucket folder. With this approach, you don't need to update your bucket policy to grant access. You can add the IAM policy to an IAM role that multiple users can switch to.

If the IAM identity and the S3 bucket belong to different AWS accounts, then you must grant cross-account access in both the IAM policy and the bucket policy. For more information about granting cross-account access, see Bucket owner granting cross-account bucket permissions.

The following example bucket policy grants *JohnDoe* full console access to only his folder (home/*JohnDoe*/). By creating a home folder and granting the appropriate permissions to your users, you can have multiple users share a single bucket. This policy consists of three `Allow` statements:

- *AllowRootAndHomeListingOfCompanyBucket*: Allows the user (*JohnDoe*) to list objects at the root level of the *amzn-s3-demo-bucket* bucket and in the home folder. This statement also allows the user to search on the prefix home/ by using the console.
- *AllowListingOfUserFolder*: Allows the user (*JohnDoe*) to list all objects in the home/*JohnDoe*/ folder and any subfolders.
- *AllowAllS3ActionsInUserFolder*: Allows the user to perform all Amazon S3 actions by granting `Read`, `Write`, and `Delete` permissions. Permissions are limited to the bucket owner's home folder.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRootAndHomeListingOfCompanyBucket",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/JohnDoe"
                ]
            },
            "Effect": "Allow",
            "Action": ["s3:ListBucket"],
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket"],
            "Condition": {
                "StringEquals": {
                    "s3:prefix": ["", "home/", "home/JohnDoe"],
                    "s3:delimiter": ["/"]
                }
            }
        },
        {
            "Sid": "AllowListingOfUserFolder",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/JohnDoe"
                ]
            },
            "Action": ["s3:ListBucket"],
            "Effect": "Allow",
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket"],
            "Condition": {
                "StringLike": {
                    "s3:prefix": ["home/JohnDoe/*"]
                }
            }
        },
        {
            "Sid": "AllowAllS3ActionsInUserFolder",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
```

```
                    "arn:aws:iam::111122223333:user/JohnDoe"
                ]
            },
            "Action": ["s3:*"],
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/home/JohnDoe/*"]
        }
    ]
}
```

Managing access for access logs

Grant access to Application Load Balancer for enabling access logs

When you enable access logs for Application Load Balancer, you must specify the name of the S3 bucket where the load balancer will store the logs. The bucket must have an attached policy that grants Elastic Load Balancing permission to write to the bucket.

In the following example, the bucket policy grants Elastic Load Balancing (ELB) permission to write the access logs to the bucket:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/
AWSLogs/111122223333/*"
        }
    ]
}
```

> **Note**
>
> Make sure to replace *elb-account-id* with the AWS account ID for Elastic Load Balancing for your AWS Region. For the list of Elastic Load Balancing Regions, see Attach a policy to your Amazon S3 bucket in the *Elastic Load Balancing User Guide*.

If your AWS Region does not appear in the supported Elastic Load Balancing Regions list, use the following policy, which grants permissions to the specified log delivery service.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
       "Principal": {
         "Service": "logdelivery.elasticloadbalancing.amazonaws.com"
          },
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/AWSLogs/111122223333/
*"
    }
  ]
}
```

Then, make sure to configure your Elastic Load Balancing access logs by enabling them. You can verify your bucket permissions by creating a test file.

Managing access to an Amazon CloudFront OAI

Grant permission to an Amazon CloudFront OAI

The following example bucket policy grants a CloudFront origin access identity (OAI) permission to get (read) all objects in your S3 bucket. You can use a CloudFront OAI to allow users to access objects in your bucket through CloudFront but not directly through Amazon S3. For more information, see Restricting access to Amazon S3 content by using an Origin Access Identity in the *Amazon CloudFront Developer Guide*.

The following policy uses the OAI's ID as the policy's `Principal`. For more information about using S3 bucket policies to grant access to a CloudFront OAI, see Migrating from origin access identity (OAI) to origin access control (OAC) in the *Amazon CloudFront Developer Guide*.

To use this example:

- Replace *EH1HDMB1FH2TC* with the OAI's ID. To find the OAI's ID, see the Origin Access Identity page on the CloudFront console, or use ListCloudFrontOriginAccessIdentities in the CloudFront API.
- Replace *amzn-s3-demo-bucket* with the name of your bucket.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "PolicyForCloudFrontPrivateContent",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access
 Identity EH1HDMB1FH2TC"
            },
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Managing access for Amazon S3 Storage Lens

Grant permissions for Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily

metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

S3 Storage Lens can export your aggregated storage usage metrics to an Amazon S3 bucket for further analysis. The bucket where S3 Storage Lens places its metrics exports is known as the *destination bucket*. When setting up your S3 Storage Lens metrics export, you must have a bucket policy for the destination bucket. For more information, see Monitoring your storage activity and usage with Amazon S3 Storage Lens.

The following example bucket policy grants Amazon S3 permission to write objects (PUT requests) to a destination bucket. You use a bucket policy like this on the destination bucket when setting up an S3 Storage Lens metrics export.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "S3StorageLensExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "storage-lens.s3.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/destination-prefix/
StorageLens/111122223333/*"
            ],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control",
                    "aws:SourceAccount": "111122223333",
                    "aws:SourceArn": "arn:aws:s3:region-
code:111122223333:storage-lens/storage-lens-dashboard-configuration-id"
                }
            }
        }
    ]
}
```

When you're setting up an S3 Storage Lens organization-level metrics export, use the following modification to the previous bucket policy's `Resource` statement.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/destination-prefix/
StorageLens/your-organization-id/*",
```

Managing permissions for S3 Inventory, S3 analytics, and S3 Inventory reports

Grant permissions for S3 Inventory and S3 analytics

S3 Inventory creates lists of the objects in a bucket, and S3 analytics Storage Class Analysis export creates output files of the data used in the analysis. The bucket that the inventory lists the objects for is called the *source bucket*. The bucket where the inventory file or the analytics export file is written to is called a *destination bucket*. When setting up an inventory or an analytics export, you must create a bucket policy for the destination bucket. For more information, see Cataloging and analyzing your data with S3 Inventory and Amazon S3 analytics – Storage Class Analysis.

The following example bucket policy grants Amazon S3 permission to write objects (PUT requests) from the account for the source bucket to the destination bucket. You use a bucket policy like this on the destination bucket when setting up S3 Inventory and S3 analytics export.

JSON

```
{
      "Version":"2012-10-17",
      "Statement": [
        {
            "Sid": "InventoryAndAnalyticsExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
            "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
            ],
            "Condition": {
                "ArnLike": {
```

```
                "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-bucket"
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

Control S3 Inventory report configuration creation

Cataloging and analyzing your data with S3 Inventory creates lists of the objects in an S3 bucket and the metadata for each object. The `s3:PutInventoryConfiguration` permission allows a user to create an inventory configuration that includes all object metadata fields that are available by default and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory report. For more information about the metadata fields that are available in S3 Inventory, see Amazon S3 Inventory list.

To restrict a user from configuring an S3 Inventory report, remove the `s3:PutInventoryConfiguration` permission from the user.

Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key. For a list of the optional metadata fields available in S3 Inventory, see OptionalFields in the *Amazon Simple Storage Service API Reference*.

> **Note**
>
> For directory buckets, use the `s3express:InventoryAccessibleOptionalFields` condition key instead of `s3:InventoryAccessibleOptionalFields`. For more information about configuring S3 Inventory for directory buckets, see Configuring Amazon S3 Inventory.

To grant a user permission to create an inventory configuration with specific optional metadata fields, use the `s3:InventoryAccessibleOptionalFields` condition key to refine the conditions in your bucket policy.

The following example policy grants a user (*Ana*) permission to create an inventory configuration conditionally. The `ForAllValues:StringEquals` condition in the policy uses the `s3:InventoryAccessibleOptionalFields` condition key to specify the two allowed optional metadata fields, namely `Size` and `StorageClass`. So, when *Ana* is creating an inventory configuration, the only optional metadata fields that she can include are `Size` and `StorageClass`.

JSON

```
{
 "Id": "InventoryConfigPolicy",
 "Version":"2012-10-17",
 "Statement": [{
   "Sid": "AllowInventoryCreationConditionally",
   "Effect": "Allow",
   "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/Ana"
   },
   "Action":
    "s3:PutInventoryConfiguration",
   "Resource":
    "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET",
   "Condition": {
    "ForAllValues:StringEquals": {
     "s3:InventoryAccessibleOptionalFields": [
        "Size",
        "StorageClass"
        ]
      }
    }
   }
 ]
}
```

To restrict a user from configuring an S3 Inventory report that includes specific optional metadata fields, add an explicit Deny statement to the bucket policy for the source bucket. The following

example bucket policy denies the user *Ana* from creating an inventory configuration in the source bucket *amzn-s3-demo-source-bucket* that includes the optional `ObjectAccessControlList` or `ObjectOwner` metadata fields. The user *Ana* can still create an inventory configuration with other optional metadata fields.

```
{
 "Id": "InventoryConfigSomeFields",
 "Version": "2012-10-17",
 "Statement": [{
   "Sid": "AllowInventoryCreation",
   "Effect": "Allow",
   "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/Ana"
   },
   "Action": "s3:PutInventoryConfiguration",
   "Resource":
    "arn:aws:s3:::amzn-s3-demo-source-bucket"

  },
  {
   "Sid": "DenyCertainInventoryFieldCreation",
   "Effect": "Deny",
   "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/Ana"
   },
   "Action": "s3:PutInventoryConfiguration",
   "Resource":
     "arn:aws:s3:::amzn-s3-demo-source-bucket",
   "Condition": {
    "ForAnyValue:StringEquals": {
     "s3:InventoryAccessibleOptionalFields": [
        "ObjectOwner",
        "ObjectAccessControlList"
        ]
      }
    }
   }
 ]
}
```

Note

The use of the `s3:InventoryAccessibleOptionalFields` condition key in bucket policies doesn't affect the delivery of inventory reports based on the existing inventory configurations.

Important

We recommend that you use `ForAllValues` with an `Allow` effect or `ForAnyValue` with a `Deny` effect, as shown in the prior examples.
Don't use `ForAllValues` with a `Deny` effect nor `ForAnyValue` with an `Allow` effect, because these combinations can be overly restrictive and block inventory configuration deletion.
To learn more about the `ForAllValues` and `ForAnyValue` condition set operators, see Multivalued context keys in the *IAM User Guide*.

Control S3 Inventory report configuration creation for directory buckets

For directory buckets, you use the `s3express:InventoryAccessibleOptionalFields` condition key in an IAM identity-based policy instead of a bucket policy. The following example IAM policy grants a user permission to create an inventory configuration for a directory bucket. The `ForAllValues:StringEquals` condition uses the `s3express:InventoryAccessibleOptionalFields` condition key to specify the allowed optional metadata fields.

```
{
 "Version": "2012-10-17",
 "Statement": [{
  "Sid": "AllowInventoryCreationForDirectoryBucket",
  "Effect": "Allow",
  "Action": "s3express:PutInventoryConfiguration",
  "Resource": "arn:aws:s3express:region:account-id:bucket/bucket-base-name--zone-id--x-
s3",
  "Condition": {
   "ForAllValues:StringEquals": {
    "s3express:InventoryAccessibleOptionalFields": [
     "Size",
```

```
      "StorageClass"
     ]
    }
   }
  }]
}
```

Requiring MFA

Amazon S3 supports MFA-protected API access, a feature that can enforce multi-factor authentication (MFA) for access to your Amazon S3 resources. Multi-factor authentication provides an extra level of security that you can apply to your AWS environment. MFA is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, see AWS Multi-Factor Authentication. You can require MFA for any requests to access your Amazon S3 resources.

To enforce the MFA requirement, use the `aws:MultiFactorAuthAge` condition key in a bucket policy. IAM users can access Amazon S3 resources by using temporary credentials issued by the AWS Security Token Service (AWS STS). You provide the MFA code at the time of the AWS STS request.

When Amazon S3 receives a request with multi-factor authentication, the `aws:MultiFactorAuthAge` condition key provides a numeric value that indicates how long ago (in seconds) the temporary credential was created. If the temporary credential provided in the request was not created by using an MFA device, this key value is null (absent). In a bucket policy, you can add a condition to check this value, as shown in the following example.

This example policy denies any Amazon S3 operation on the */taxdocuments* folder in the *amzn-s3-demo-bucket* bucket if the request is not authenticated by using MFA. To learn more about MFA, see Using Multi-Factor Authentication (MFA) in AWS in the *IAM User Guide*.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "123",
    "Statement": [
      {
        "Sid": "",
        "Effect": "Deny",
```

```
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": { "Null": { "aws:MultiFactorAuthAge": true }}
      }
    ]
 }
```

The `Null` condition in the `Condition` block evaluates to `true` if the `aws:MultiFactorAuthAge` condition key value is null, indicating that the temporary security credentials in the request were created without an MFA device.

The following bucket policy is an extension of the preceding bucket policy. The following policy includes two policy statements. One statement allows the `s3:GetObject` permission on a bucket (*amzn-s3-demo-bucket*) to everyone. Another statement further restricts access to the *amzn-s3-demo-bucket/taxdocuments* folder in the bucket by requiring MFA.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "123",
    "Statement": [
      {
        "Sid": "DenyInsecureConnections",
        "Effect": "Deny",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:root"
        },
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": { "Null": { "aws:MultiFactorAuthAge": true } }
      },
      {
        "Sid": "AllowGetObject",
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:root"
        },
        "Action": ["s3:GetObject"],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

```
      }
    ]
}
```

You can optionally use a numeric condition to limit the duration for which the `aws:MultiFactorAuthAge` key is valid. The duration that you specify with the `aws:MultiFactorAuthAge` key is independent of the lifetime of the temporary security credential that's used in authenticating the request.

For example, the following bucket policy, in addition to requiring MFA authentication, also checks how long ago the temporary session was created. The policy denies any operation if the `aws:MultiFactorAuthAge` key value indicates that the temporary session was created more than an hour ago (3,600 seconds).

JSON

```
{
    "Version":"2012-10-17",
    "Id": "123",
    "Statement": [
      {
        "Sid": "",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": {"Null": {"aws:MultiFactorAuthAge": true }}
      },
      {
        "Sid": "",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/taxdocuments/*",
        "Condition": {"NumericGreaterThan": {"aws:MultiFactorAuthAge": 3600 }}
       },
       {
         "Sid": "",
         "Effect": "Allow",
         "Principal": "*",
         "Action": ["s3:GetObject"],
```

```
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
      }
    ]
}
```

Preventing users from deleting objects

By default, users have no permissions. But as you create policies, you might grant users permissions that you didn't intend to grant. To avoid such permission loopholes, you can write a stricter access policy by adding an explicit deny.

To explicitly block users or accounts from deleting objects, you must add the following actions to a bucket policy: `s3:DeleteObject`, `s3:DeleteObjectVersion`, and `s3:PutLifecycleConfiguration` permissions. All three actions are required because you can delete objects either by explicitly calling the `DELETE Object` API operations or by configuring their lifecycle (see Managing the lifecycle of objects) so that Amazon S3 can remove the objects when their lifetime expires.

In the following policy example, you explicitly deny `DELETE Object` permissions to the user *`MaryMajor`*. An explicit Deny statement always supersedes any other permission granted.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "statement1",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/MaryMajor"
      },
      "Action": [
        "s3:GetObjectVersion",
        "s3:GetBucketAcl"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket1",
   "arn:aws:s3:::amzn-s3-demo-bucket1/*"
      ]
```

```
    },
    {
      "Sid": "statement2",
      "Effect": "Deny",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/MaryMajor"
      },
      "Action": [
        "s3:DeleteObject",
        "s3:DeleteObjectVersion",
        "s3:PutLifecycleConfiguration"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket1",
     "arn:aws:s3:::amzn-s3-demo-bucket1/*"
      ]
    }
  ]
}
```

Bucket policy examples using condition keys

You can use access policy language to specify conditions when you grant permissions. You can use the optional `Condition` element, or `Condition` block, to specify conditions for when a policy is in effect.

For policies that use Amazon S3 condition keys for object and bucket operations, see the following examples. For more information about condition keys, see Policy condition keys for Amazon S3. For a complete list of Amazon S3 actions, condition keys, and resources that you can specify in policies, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Examples: Amazon S3 condition keys for object operations

The following examples show how you can use Amazon S3-specific condition keys for object operations. For a complete list of Amazon S3 actions, condition keys, and resources that you can specify in policies, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Several of the example policies show how you can use conditions keys with PUT Object operations. PUT Object operations allow access control list (ACL)–specific headers that you can use to grant ACL-based permissions. By using these condition keys, you can set a condition to require specific access permissions when the user uploads an object. You can also grant ACL–based permissions with the PutObjectAcl operation. For more information, see PutObjectAcl in the *Amazon S3 Amazon Simple Storage Service API Reference*. For more information about ACLs, see Access control list (ACL) overview.

Topics

- Example 1: Granting s3:PutObject permission requiring that objects be stored using server-side encryption
- Example 2: Granting s3:PutObject permission to copy objects with a restriction on the copy source
- Example 3: Granting access to a specific version of an object
- Example 4: Granting permissions based on object tags
- Example 5: Restricting access by the AWS account ID of the bucket owner
- Example 6: Requiring a minimum TLS version
- Example 7: Excluding certain principals from a Deny statement
- Example 8: Enforcing clients to conditionally upload objects based on object key names or ETags
- Example 9: Restricting annotation listing by name prefix
- Example 10: Requiring conditional writes for annotation operations
- Example 11: Limiting pagination size for ListObjectAnnotations

Example 1: Granting `s3:PutObject` permission requiring that objects be stored using server-side encryption

Suppose that Account A owns a bucket. The account administrator wants to grant Jane, a user in Account A, permission to upload objects with the condition that Jane always request server-side encryption with Amazon S3 managed keys (SSE-S3). The Account A administrator can specify this requirement by using the `s3:x-amz-server-side-encryption` condition key as shown. The key-value pair in the following `Condition` block specifies the `s3:x-amz-server-side-encryption` condition key and SSE-S3 (`AES256`) as the encryption type:

```
"Condition": {
     "StringNotEquals": {
         "s3:x-amz-server-side-encryption": "AES256"
     }}
```

When testing this permission by using the AWS CLI, you must add the required encryption by using the `--server-side-encryption` parameter, as shown in the following example. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key HappyFace.jpg --body c:
\HappyFace.jpg --server-side-encryption "AES256" --profile AccountAadmin
```

Example 2: Granting `s3:PutObject` permission to copy objects with a restriction on the copy source

In a PUT object request, when you specify a source object, the request is a copy operation (see CopyObject). Accordingly, the bucket owner can grant a user permission to copy objects with restrictions on the source, for example:

- Allow copying objects only from the specified source bucket (for example, *amzn-s3-demo-source-bucket*).
- Allow copying objects from the specified source bucket and only the objects whose key name prefix starts with as specific prefix, such as *public/* (for example, *amzn-s3-demo-source-bucket/public/**).
- Allow copying only a specific object from the source bucket (for example, *amzn-s3-demo-source-bucket/example.jpg*).

The following bucket policy grants a user (*Dave*) the `s3:PutObject` permission. This policy allows him to copy objects only with a condition that the request include the `s3:x-amz-copy-source` header and that the header value specify the */amzn-s3-demo-source-bucket/public/** key name prefix. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [
       {
            "Sid": "cross-account permission to user in your own account",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
        },
        {
            "Sid": "Deny your user permission to upload object if copy source is
 not /bucket/prefix",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-source-bucket/*",
            "Condition": {
                "StringNotLike": {
                    "s3:x-amz-copy-source": "amzn-s3-demo-source-bucket/public/*"
                }
            }
        }
    ]
}
```

Test the policy with the AWS CLI

You can test the permission using the AWS CLI `copy-object` command. You specify the source by adding the `--copy-source` parameter; the key name prefix must match the prefix allowed in the policy. You need to provide the user Dave credentials using the `--profile` parameter. For more information about setting up the AWS CLI, see Developing with Amazon S3 using the AWS CLI in the *Amazon S3 API Reference*.

```
aws s3api copy-object --bucket amzn-s3-demo-source-bucket --key HappyFace.jpg
--copy-source amzn-s3-demo-source-bucket/public/PublicHappyFace1.jpg --
profile AccountADave
```

Give permission to copy only a specific object

The preceding policy uses the `StringNotLike` condition. To grant permission to copy only a specific object, you must change the condition from `StringNotLike` to `StringNotEquals` and then specify the exact object key, as shown in the following example. To use this example command, replace the *`user input placeholders`* with your own information.

```
"Condition": {
       "StringNotEquals": {
           "s3:x-amz-copy-source": "amzn-s3-demo-source-bucket/public/
PublicHappyFace1.jpg"
       }
}
```

Example 3: Granting access to a specific version of an object

Suppose that Account A owns a versioning-enabled bucket. The bucket has several versions of the *`HappyFace.jpg`* object. The Account A administrator now wants to grant the user *`Dave`* permission to get only a specific version of the object. The account administrator can accomplish this by granting the user *`Dave`* the `s3:GetObjectVersion` permission conditionally, as shown in the following example. The key-value pair in the `Condition` block specifies the `s3:VersionId` condition key. In this case, to retrieve the object from the specified versioning-enabled bucket, *`Dave`* needs to know the exact object version ID. To use this example policy, replace the *`user input placeholders`* with your own information.

For more information, see GetObject in the *Amazon Simple Storage Service API Reference*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:GetObjectVersion",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/HappyFace.jpg"
        },
        {
```

```
            "Sid": "statement2",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": "s3:GetObjectVersion",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/HappyFace.jpg",
            "Condition": {
                "StringNotEquals": {
                    "s3:VersionId": "AaaHbAQitwiL_h47_44lRO2DDfLlBO5e"
                }
            }
        }
    ]
}
```

Test the policy with the AWS CLI

You can test the permissions in this policy by using the AWS CLI `get-object` command with the `--version-id` parameter to identify the specific object version to retrieve. The command retrieves the specified version of the object and saves it to the *`OutputFile.jpg`* file.

```
aws s3api get-object --bucket amzn-s3-demo-bucket --key HappyFace.jpg OutputFile.jpg --
version-id AaaHbAQitwiL_h47_44lRO2DDfLlBO5e --profile AccountADave
```

Example 4: Granting permissions based on object tags

For examples of how to use object tagging condition keys with Amazon S3 operations, see Tagging and access control policies.

Example 5: Restricting access by the AWS account ID of the bucket owner

You can use either the `aws:ResourceAccount` or `s3:ResourceAccount` condition key to write IAM or virtual private cloud (VPC) endpoint policies that restrict user, role, or application access to the Amazon S3 buckets that are owned by a specific AWS account ID. You can use these condition keys to restrict clients within your VPC from accessing buckets that you don't own.

However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources. For more information, see the following resources:

- Restrict access to buckets in a specified AWS account in the *AWS PrivateLink Guide*
- Restrict access to buckets that Amazon ECR uses in the *Amazon ECR Guide*
- Provide required access to Systems Manager for AWS managed Amazon S3 buckets in the *AWS Systems Manager Guide*

For more information about the `aws:ResourceAccount` and `s3:ResourceAccount` condition keys and examples that show how to use them, see Limit access to Amazon S3 buckets owned by specific AWS accounts in the *AWS Storage Blog*.

Example 6: Requiring a minimum TLS version

You can use the `s3:TlsVersion` condition key to write IAM, virtual private cloud endpoint (VPCE), or bucket policies that restrict user or application access to Amazon S3 buckets based on the TLS version that's used by the client. You can use this condition key to write policies that require a minimum TLS version.

Note

When AWS services make calls to other AWS services on your behalf (service-to-service calls), certain network-specific authorization context is redacted, including `s3:TlsVersion`, `aws:SecureTransport`, `aws:SourceIp`, and `aws:VpcSourceIp`. If your policy uses these condition keys with `Deny` statements, AWS service principals might be unintentionally blocked. To allow AWS services to work properly while maintaining your security requirements, exclude service principals from your `Deny` statements by adding the `aws:PrincipalIsAWSService` condition key with a value of `false`. For example:

```
{
  "Effect": "Deny",
  "Action": "s3:*",
  "Resource": "*",
  "Condition": {
    "Bool": {
      "aws:SecureTransport": "false",
      "aws:PrincipalIsAWSService": "false"
    }
  }
}
```

This policy denies access to S3 operations when HTTPS is not used (`aws:SecureTransport` is false), but only for non-AWS service principals. This ensures your conditional restrictions apply to all principals except AWS service principals.

Example

The following example bucket policy *denies* `PutObject` requests by clients that have a TLS version earlier than 1.2, for example, 1.1 or 1.0. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1",
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ],
            "Condition": {
                "NumericLessThan": {
                    "s3:TlsVersion": 1.2
                }
            }
        }
    ]
}
```

Example

The following example bucket policy *allows* `PutObject` requests by clients that have a TLS version later than 1.1, for example, 1.2, 1.3, or later:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1",
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ],
            "Condition": {
                "NumericGreaterThan": {
                    "s3:TlsVersion": 1.1
                }
            }
        }
    ]
}
```

Example 7: Excluding certain principals from a Deny statement

The following bucket policy denies `s3:GetObject` access to the *amzn-s3-demo-bucket*, except to principals with the account number *123456789012*. To use this example policy, replace the *user input placeholders* with your own information.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "DenyAccessFromPrincipalNotInSpecificAccount",
      "Principal": {
        "AWS": "*"
      },
```

```
      "Action": "s3:GetObject",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:PrincipalAccount": [
            "123456789012"
          ]
        }
      }
    }
  ]
}
```

Example 8: Enforcing clients to conditionally upload objects based on object key names or ETags

With conditional writes, you can add an additional header to your `WRITE` requests in order to specify preconditions for your S3 operation. This header specifies a condition that, if not met, will result in the S3 operation failing. For example you can prevent overwrites of existing data by validating there is no object with the same key name already in your bucket during object upload. You can alternatively check an object's entity tag (ETag) in Amazon S3 before writing an object.

For bucket policy examples that use conditions in a bucket policy to enforce conditional writes, see the section called “Enforce conditional writes”.

Example 9: Restricting annotation listing by name prefix

The following bucket policy grants the `s3user` user permission to list only the annotations whose names start with `ml-output` on objects in `amzn-s3-demo-bucket`. The `s3:annotation-prefix` condition key applies only to the `ListObjectAnnotations` and `ListObjectVersionAnnotations` actions.

> **Note**
>
> You can't use `s3:annotation-prefix` with `PutObjectAnnotation`, `GetObjectAnnotation`, or `DeleteObjectAnnotation`. If a policy statement combines

this condition key with those actions, IAM rejects the policy with the error `Conditions do not apply to combination of actions and resources in statement`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/s3user"
            },
            "Action": [
                "s3:ListObjectAnnotations",
                "s3:ListObjectVersionAnnotations"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringLike": {
                    "s3:annotation-prefix": "ml-output*"
                }
            }
        }
    ]
}
```

Example 10: Requiring conditional writes for annotation operations

The following bucket policy denies `PutObjectAnnotation` and `DeleteObjectAnnotation` requests unless the caller includes the `x-amz-object-if-match` conditional header. This enforces optimistic concurrency control for all annotation writes on the bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RequireConditionalWritesForAnnotations",
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:PutObjectAnnotation",
                "s3:DeleteObjectAnnotation"
```

```
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "Null": {
                    "s3:x-amz-object-if-match": "true"
                }
            }
        }
    ]
}
```

Example 11: Limiting pagination size for ListObjectAnnotations

The following bucket policy limits the `max-annotation-results` parameter to 100 or fewer for all `ListObjectAnnotations` requests. This prevents callers from requesting excessively large result sets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "LimitAnnotationListPageSize",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:ListObjectAnnotations",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "NumericGreaterThan": {
                    "s3:max-annotation-results": "100"
                }
            }
        }
    ]
}
```

Examples: Amazon S3 condition keys for bucket operations

The following example policies show how you can use Amazon S3 specific condition keys for bucket operations.

Topics

- Example 1: Granting s3:GetObject permission with a condition on an IP address

- Example 2: Getting a list of objects in a bucket with a specific prefix
- Example 3: Setting the maximum number of keys

Example 1: Granting `s3:GetObject` permission with a condition on an IP address

You can give authenticated users permission to use the `s3:GetObject` action if the request originates from a specific range of IP addresses (for example, *`192.0.2.*`*), unless the IP address is one that you want to exclude (for example, *`192.0.2.188`*). In the `Condition` block, `IpAddress` and `NotIpAddress` are conditions, and each condition is provided a key-value pair for evaluation. Both of the key-value pairs in this example use the `aws:SourceIp` AWS wide key. To use this example policy, replace the *`user input placeholders`* with your own information.

> **Note**
>
> The `IPAddress` and `NotIpAddress` key values specified in the `Condition` block use CIDR notation, as described in RFC 4632. For more information, see http://www.rfc-editor.org/rfc/rfc4632.txt.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "S3PolicyId1",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": "*",
            "Action":"s3:GetObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition" : {
                "IpAddress" : {
                    "aws:SourceIp": "192.0.2.0/24"
                },
                "NotIpAddress" : {
                    "aws:SourceIp": "192.0.2.188/32"
                }
            }
```

```
        }
    ]
}
```

You can also use other AWS-wide condition keys in Amazon S3 policies. For example, you can specify the `aws:SourceVpce` and `aws:SourceVpc` condition keys in bucket policies for VPC endpoints. For specific examples, see Controlling access from VPC endpoints with bucket policies.

> **Note**
>
> For some AWS global condition keys, only certain resource types are supported. Therefore, check whether Amazon S3 supports the global condition key and resource type that you want to use, or if you'll need to use an Amazon S3 specific condition key instead. For a complete list of supported resource types and condition keys for Amazon S3, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.
> For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Example 2: Getting a list of objects in a bucket with a specific prefix

You can use the `s3:prefix` condition key to limit the response of the ListObjectsV2 API operation to key names with a specific prefix. If you are the bucket owner, you can use this condition key to restrict a user to list the contents of a specific prefix in the bucket. The `s3:prefix` condition key is useful if the objects in the bucket are organized by key name prefixes.

The Amazon S3 console uses key name prefixes to show a folder concept. Only the console supports the concept of folders; the Amazon S3 API supports only buckets and objects. For example, if you have two objects with the key names *`public/object1.jpg`* and *`public/object2.jpg`*, the console shows the objects under the *`public`* folder. In the Amazon S3 API, these are objects with prefixes, not objects in folders. For more information about using prefixes and delimiters to filter access permissions, see Controlling access to a bucket with user policies.

In the following scenario, the bucket owner and the parent account to which the user belongs are the same. So the bucket owner can use either a bucket policy or a user policy to grant access. For more information about other condition keys that you can use with the `ListObjectsV2` API operation, see ListObjectsV2.

Note

If the bucket is versioning-enabled, to list the objects in the bucket, you must grant the `s3:ListBucketVersions` permission in the following policies, instead of the `s3:ListBucket` permission. The `s3:ListBucketVersions` permission also supports the `s3:prefix` condition key.

User policy

The following user policy grants the `s3:ListBucket` permission (see ListObjectsV2) with a `Condition` statement that requires the user to specify a prefix in the request with a value of *`projects`*. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action": "s3:ListBucket",
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket",
         "Condition" : {
             "StringEquals" : {
                 "s3:prefix": "projects"
             }
          }
       },
      {
         "Sid":"statement2",
         "Effect":"Deny",
         "Action": "s3:ListBucket",
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
         "Condition" : {
             "StringNotEquals" : {
                 "s3:prefix": "projects"
             }
          }
```

```
        }
    ]
}
```

The `Condition` statement restricts the user to listing only object keys that have the *`projects`* prefix. The added explicit `Deny` statement denies the user from listing keys with any other prefix, no matter what other permissions the user might have. For example, it's possible that the user could get permission to list object keys without any restriction, either through updates to the preceding user policy or through a bucket policy. Because explicit `Deny` statements always override `Allow` statements, if the user tries to list keys other than those that have the *`projects`* prefix, the request is denied.

Bucket policy

If you add the `Principal` element to the above user policy, identifying the user, you now have a bucket policy, as shown in the following example. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/bucket-owner"
         },
         "Action":  "s3:ListBucket",
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
         "Condition" : {
             "StringEquals" : {
                 "s3:prefix": "projects"
             }
          }
       },
      {
         "Sid":"statement2",
         "Effect":"Deny",
```

```
            "Principal": {
               "AWS": "arn:aws:iam::123456789012:user/bucket-owner"
            },
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
            "Condition" : {
                "StringNotEquals" : {
                    "s3:prefix": "projects"
                }
             }
          }
       ]
}
```

Test the policy with the AWS CLI

You can test the policy using the following `list-object` AWS CLI command. In the command, you provide user credentials using the `--profile` parameter. For more information about setting up and using the AWS CLI, see Developing with Amazon S3 using the AWS CLI in the *Amazon S3 API Reference*.

```
aws s3api list-objects --bucket amzn-s3-demo-bucket --prefix projects --
profile AccountA
```

Example 3: Setting the maximum number of keys

You can use the `s3:max-keys` condition key to set the maximum number of keys that a requester can return in a ListObjectsV2 or ListObjectVersions request. By default, these API operations return up to 1,000 keys. For a list of numeric condition operators that you can use with `s3:max-keys` and accompanying examples, see Numeric Condition Operators in the *IAM User Guide*.

Identity-based policies for Amazon S3

By default, users and roles don't have permission to create or modify Amazon S3 resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by Amazon S3, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Topics

- Policy best practices
- Controlling access to a bucket with user policies
- Identity-based policy examples for Amazon S3

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon S3 resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies

adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.

- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Controlling access to a bucket with user policies

This walkthrough explains how user permissions work with Amazon S3. In this example, you create a bucket with folders. You then create AWS Identity and Access Management IAM users in your AWS account and grant those users incremental permissions on your Amazon S3 bucket and the folders in it.

Topics

- Basics of buckets and folders
- Walkthrough summary
- Preparing for the walkthrough
- Step 1: Create a bucket
- Step 2: Create IAM users and a group
- Step 3: Verify that IAM users have no permissions
- Step 4: Grant group-level permissions
- Step 5: Grant IAM user Alice specific permissions
- Step 6: Grant IAM user Bob specific permissions
- Step 7: Secure the private folder
- Step 8: Clean up
- Related resources

Basics of buckets and folders

The Amazon S3 data model is a flat structure: You create a bucket, and the bucket stores objects. There is no hierarchy of subbuckets or subfolders, but you can emulate a folder hierarchy. Tools like the Amazon S3 console can present a view of these logical folders and subfolders in your bucket.

The console shows that a bucket named `companybucket` has three folders, `Private`, `Development`, and `Finance`, and an object, `s3-dg.pdf`. The console uses the object names (keys) to create a logical hierarchy with folders and subfolders. Consider the following examples:

- When you create the `Development` folder, the console creates an object with the key `Development/`. Note the trailing slash (/) delimiter.
- When you upload an object named `Projects1.xls` in the `Development` folder, the console uploads the object and gives it the key `Development/Projects1.xls`.

  In the key, `Development` is the prefix and / is the delimiter. The Amazon S3 API supports prefixes and delimiters in its operations. For example, you can get a list of all objects from a bucket with a specific prefix and delimiter. On the console, when you open the `Development` folder, the console lists the objects in that folder. In the following example, the `Development` folder contains one object.

  When the console lists the `Development` folder in the `companybucket` bucket, it sends a request to Amazon S3 in which it specifies a prefix of `Development` and a delimiter of / in the request. The console's response looks just like a folder list in your computer's file system. The preceding example shows that the bucket `companybucket` has an object with the key `Development/Projects1.xls`.

The console is using object keys to infer a logical hierarchy. Amazon S3 has no physical hierarchy. Amazon S3 only has buckets that contain objects in a flat file structure. When you create objects using the Amazon S3 API, you can use object keys that imply a logical hierarchy. When you create a logical hierarchy of objects, you can manage access to individual folders, as this walkthrough demonstrates.

Before you start, be sure that you are familiar with the concept of the *root-level* bucket content. Suppose that your `companybucket` bucket has the following objects:

- `Private/privDoc1.txt`
- `Private/privDoc2.zip`

- Development/project1.xls
- Development/project2.xls
- Finance/Tax2011/document1.pdf
- Finance/Tax2011/document2.pdf
- s3-dg.pdf

These object keys create a logical hierarchy with Private, Development, and the Finance as root-level folders and s3-dg.pdf as a root-level object. When you choose the bucket name on the Amazon S3 console, the root-level items appear. The console shows the top-level prefixes (Private/, Development/, and Finance/) as root-level folders. The object key s3-dg.pdf has no prefix, and so it appears as a root-level item.

Walkthrough summary

In this walkthrough, you create a bucket with three folders (Private, Development, and Finance) in it.

You have two users, Alice and Bob. You want Alice to access only the Development folder, and you want Bob to access only the Finance folder. You want to keep the Private folder content private. In the walkthrough, you manage access by creating IAM users (the example uses the usernames Alice and Bob) and granting them the necessary permissions.

IAM also supports creating user groups and granting group-level permissions that apply to all users in the group. This helps you better manage permissions. For this exercise, both Alice and Bob need some common permissions. So you also create a group named Consultants and then add both Alice and Bob to the group. You first grant permissions by attaching a group policy to the group. Then you add user-specific permissions by attaching policies to specific users.

> **Note**
>
> The walkthrough uses companybucket as the bucket name, Alice and Bob as the IAM users, and Consultants as the group name. Because Amazon S3 requires that bucket names be globally unique, you must replace the bucket name with a name that you create.

Preparing for the walkthrough

In this example, you use your AWS account credentials to create IAM users. Initially, these users have no permissions. You incrementally grant these users permissions to perform specific Amazon S3 actions. To test these permissions, you sign in to the console with each user's credentials. As you incrementally grant permissions as an AWS account owner and test permissions as an IAM user, you need to sign in and out, each time using different credentials. You can do this testing with one browser, but the process will go faster if you can use two different browsers. Use one browser to connect to the AWS Management Console with your AWS account credentials and another browser to connect with the IAM user credentials.

To sign in to the AWS Management Console with your AWS account credentials, go to https://console.aws.amazon.com/. An IAM user can't sign in using the same link. An IAM user must use an IAM-enabled sign-in page. As the account owner, you can provide this link to your users.

For more information about IAM, see The AWS Management Console Sign-in Page in the *IAM User Guide*.

To provide a sign-in link for IAM users

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the **Navigation** pane, choose **IAM Dashboard** .
3. Note the URL under **IAM users sign in link:**. You will give this link to IAM users to sign in to the console with their IAM user name and password.

Step 1: Create a bucket

In this step, you sign in to the Amazon S3 console with your AWS account credentials, create a bucket, add folders to the bucket, and upload one or two sample documents in each folder.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create a bucket.

   For step-by-step instructions, see Creating a general purpose bucket.
3. Upload one document to the bucket.

This exercise assumes that you have the `s3-dg.pdf` document at the root level of this bucket. If you upload a different document, substitute its file name for `s3-dg.pdf`.

4. Add three folders named `Private`, `Finance`, and `Development` to the bucket.

   For step-by-step instructions to create a folder, see Organizing objects in the Amazon S3 console by using folders> in the *Amazon Simple Storage Service User Guide*.

5. Upload one or two documents to each folder.

   For this exercise, assume that you have uploaded a couple of documents in each folder, resulting in the bucket having objects with the following keys:

   - `Private/privDoc1.txt`
   - `Private/privDoc2.zip`
   - `Development/project1.xls`
   - `Development/project2.xls`
   - `Finance/Tax2011/document1.pdf`
   - `Finance/Tax2011/document2.pdf`
   - `s3-dg.pdf`

   For step-by-step instructions, see Uploading objects.

Step 2: Create IAM users and a group

Now use the IAM Console to add two IAM users, Alice and Bob, to your AWS account. For step-by-step instructions, see Creating an IAM user in your AWS account in the *IAM User Guide*.

Also create an administrative group named `Consultants`. Then add both users to the group. For step-by-step instructions, see Creating IAM user groups.

> **Warning**
>
> When you add users and a group, do not attach any policies that grant permissions to these users. At first, these users don't have any permissions. In the following sections, you grant permissions incrementally. First you must ensure that you have assigned passwords to

these IAM users. You use these user credentials to test Amazon S3 actions and verify that the permissions work as expected.

For step-by-step instructions for creating a new IAM user, see Creating an IAM user in your AWS account in the *IAM User Guide*. When you create the users for this walkthrough, select **AWS Management Console access** and clear programmatic access.

For step-by-step instructions for creating an administrative group, see Creating Your First IAM Admin User and Group in the *IAM User Guide*.

Step 3: Verify that IAM users have no permissions

If you are using two browsers, you can now use the second browser to sign in to the console using one of the IAM user credentials.

1. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the AWS Management Console using either of the IAM user credentials.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   Verify the console message telling you that access is denied.

Now, you can begin granting incremental permissions to the users. First, you attach a group policy that grants permissions that both users must have.

Step 4: Grant group-level permissions

You want the users to be able to do the following:

- List all buckets owned by the parent account. To do so, Bob and Alice must have permission for the `s3:ListAllMyBuckets` action.
- List root-level items, folders, and objects in the `companybucket` bucket. To do so, Bob and Alice must have permission for the `s3:ListBucket` action on the `companybucket` bucket.

First, you create a policy that grants these permissions, and then you attach it to the `Consultants` group.

Step 4.1: Grant permission to list all buckets

In this step, you create a managed policy that grants the users minimum permissions to enable them to list all buckets owned by the parent account. Then you attach the policy to the `Consultants` group. When you attach the managed policy to a user or a group, you grant the user or group permission to obtain a list of buckets owned by the parent AWS account.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

   > **Note**
   >
   > Because you are granting user permissions, sign in using your AWS account credentials, not as an IAM user.

2. Create the managed policy.

   a. In the navigation pane on the left, choose **Policies**, and then choose **Create Policy**.

   b. Choose the **JSON** tab.

   c. Copy the following access policy and paste it into the policy text field.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGroupToSeeBucketListInTheConsole",
      "Action": ["s3:ListAllMyBuckets"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::*"]
    }
  ]
}
```

   A policy is a JSON document. In the document, a `Statement` is an array of objects, each describing a permission using a collection of name-value pairs. The preceding policy describes one specific permission. The `Action` specifies the type of access. In the policy,

the `s3:ListAllMyBuckets` is a predefined Amazon S3 action. This action covers the Amazon S3 GET Service operation, which returns a list of all buckets owned by the authenticated sender. The `Effect` element value determines whether specific permission is allowed or denied.

d. Choose **Review Policy**. On the next page, enter `AllowGroupToSeeBucketListInTheConsole` in the **Name** field, and then choose **Create policy**.

> **Note**
>
> The **Summary** entry displays a message stating that the policy does not grant any permissions. For this walkthrough, you can safely ignore this message.

3. Attach the `AllowGroupToSeeBucketListInTheConsole` managed policy that you created to the `Consultants` group.

   For step-by-step instructions for attaching a managed policy, see Adding and removing IAM identity permissions in the *IAM User Guide*.

   You attach policy documents to IAM users and groups in the IAM console. Because you want both users to be able to list the buckets, you attach the policy to the group.

4. Test the permission.

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the console using any one of IAM user credentials.

   b. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

      The console should now list all the buckets but not the objects in any of the buckets.

Step 4.2: Enable users to list root-level content of a bucket

Next, you allow all users in the `Consultants` group to list the root-level `companybucket` bucket items. When a user chooses the company bucket on the Amazon S3 console, the user can see the root-level items in the bucket.

> **Note**
>
> This example uses `companybucket` for illustration. You must use the name of the bucket that you created.

To understand the request that the console sends to Amazon S3 when you choose a bucket name, the response that Amazon S3 returns, and how the console interprets the response, examine the flow a little more closely.

When you choose a bucket name, the console sends the GET Bucket (List Objects) request to Amazon S3. This request includes the following parameters:

- The `prefix` parameter with an empty string as its value.
- The `delimiter` parameter with `/` as its value.

The following is an example request.

```
GET ?prefix=&delimiter=/ HTTP/1.1
Host: companybucket.s3.amazonaws.com
Date: Wed, 01 Aug  2012 12:00:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
```

Amazon S3 returns a response that includes the following `<ListBucketResult/>` element.

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>companybucket</Name>
  <Prefix></Prefix>
  <Delimiter>/</Delimiter>
   ...
  <Contents>
    <Key>s3-dg.pdf</Key>
    ...
  </Contents>
  <CommonPrefixes>
    <Prefix>Development/</Prefix>
  </CommonPrefixes>
  <CommonPrefixes>
    <Prefix>Finance/</Prefix>
  </CommonPrefixes>
```

```
  <CommonPrefixes>
    <Prefix>Private/</Prefix>
  </CommonPrefixes>
</ListBucketResult>
```

The key `s3-dg.pdf` object does not contain the slash (/) delimiter, and Amazon S3 returns the key in the `<Contents>` element. However, all other keys in the example bucket contain the / delimiter. Amazon S3 groups these keys and returns a `<CommonPrefixes>` element for each of the distinct prefix values `Development/`, `Finance/`, and `Private/` that is a substring from the beginning of these keys to the first occurrence of the specified / delimiter.

The console interprets this result and displays the root-level items as three folders and one object key.

If Bob or Alice opens the **Development** folder, the console sends the GET Bucket (List Objects) request to Amazon S3 with the `prefix` and the `delimiter` parameters set to the following values:

- The `prefix` parameter with the value `Development/`.
- The `delimiter` parameter with the "/" value.

In response, Amazon S3 returns the object keys that start with the specified prefix.

```
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>companybucket</Name>
  <Prefix>Development</Prefix>
  <Delimiter>/</Delimiter>
   ...
  <Contents>
    <Key>Project1.xls</Key>
    ...
  </Contents>
  <Contents>
    <Key>Project2.xls</Key>
    ...
  </Contents>
</ListBucketResult>
```

The console shows the object keys.

Now, return to granting users permission to list the root-level bucket items. To list bucket content, users need permission to call the `s3:ListBucket` action, as shown in the following policy statement. To ensure that they see only the root-level content, you add a condition that users must specify an empty `prefix` in the request—that is, they are not allowed to open any of the root-level folders. Finally, you add a condition to require folder-style access by requiring user requests to include the `delimiter` parameter with the value "/".

```
{
  "Sid": "AllowRootLevelListingOfCompanyBucket",
  "Action": ["s3:ListBucket"],
  "Effect": "Allow",
  "Resource": ["arn:aws:s3:::companybucket"],
  "Condition":{
         "StringEquals":{
             "s3:prefix":[""], "s3:delimiter":["/"]
                       }
              }
}
```

When you choose a bucket on the Amazon S3 console, the console first sends the GET Bucket location request to find the AWS Region where the bucket is deployed. Then the console uses the Region-specific endpoint for the bucket to send the GET Bucket (List Objects) request. As a result, if users are going to use the console, you must grant permission for the `s3:GetBucketLocation` action as shown in the following policy statement.

```
{
   "Sid": "RequiredByS3Console",
   "Action": ["s3:GetBucketLocation"],
   "Effect": "Allow",
   "Resource": ["arn:aws:s3:::*"]
}
```

To enable users to list root-level bucket content

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.
2. Replace the existing `AllowGroupToSeeBucketListInTheConsole` managed policy that is attached to the `Consultants` group with the following policy, which also allows the

`s3:ListBucket` action. Remember to replace *`companybucket`* in the policy `Resource` with the name of your bucket.

For step-by-step instructions, see Editing IAM policies in the *IAM User Guide*. When following the step-by-step instructions, be sure to follow the steps for applying your changes to all principal entities that the policy is attached to.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
     {
       "Sid":
 "AllowGroupToSeeBucketListAndAlsoAllowGetBucketLocationRequiredForListBucket",
       "Action": [ "s3:ListAllMyBuckets", "s3:GetBucketLocation" ],
       "Effect": "Allow",
       "Resource": [ "arn:aws:s3:::*"  ]
     },
     {
       "Sid": "AllowRootLevelListingOfCompanyBucket",
       "Action": ["s3:ListBucket"],
       "Effect": "Allow",
       "Resource": ["arn:aws:s3:::companybucket"],
       "Condition":{
             "StringEquals":{
                    "s3:prefix":[""], "s3:delimiter":["/"]
                           }
                  }
     }
  ]
}
```

3. Test the updated permissions.

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the AWS Management Console.

      Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

b. Choose the bucket that you created, and the console shows the root-level bucket items. If you choose any folders in the bucket, you won't be able to see the folder content because you haven't yet granted those permissions.

This test succeeds when users use the Amazon S3 console. When you choose a bucket on the console, the console implementation sends a request that includes the `prefix` parameter with an empty string as its value and the `delimiter` parameter with "`/`" as its value.

Step 4.3: Summary of the group policy

The net effect of the group policy that you added is to grant the IAM users Alice and Bob the following minimum permissions:

- List all buckets owned by the parent account.
- See root-level items in the `companybucket` bucket.

However, the users still can't do much. Next, you grant user-specific permissions, as follows:

- Allow Alice to get and put objects in the `Development` folder.
- Allow Bob to get and put objects in the `Finance` folder.

For user-specific permissions, you attach a policy to the specific user, not to the group. In the following section, you grant Alice permission to work in the `Development` folder. You can repeat the steps to grant similar permission to Bob to work in the `Finance` folder.

Step 5: Grant IAM user Alice specific permissions

Now you grant additional permissions to Alice so that she can see the content of the `Development` folder and get and put objects in that folder.

Step 5.1: Grant IAM user Alice permission to list the development folder content

For Alice to list the `Development` folder content, you must apply a policy to the user Alice that grants permission for the `s3:ListBucket` action on the `companybucket` bucket, provided the request includes the prefix `Development/`. You want this policy to be applied only to the user Alice, so you use an inline policy. For more information about inline policies, see Managed policies and inline policies in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Create an inline policy to grant the user Alice permission to list the `Development` folder content.

   a. In the navigation pane on the left, choose **Users**.

   b. Choose the username **Alice**.

   c. On the user details page, choose the **Permissions** tab and then choose **Add inline policy**.

   d. Choose the **JSON** tab.

   e. Copy the following policy, and paste it into the policy text field.

      JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
      "Sid": "AllowListBucketIfSpecificPrefixIsIncludedInRequest",
      "Action": ["s3:ListBucket"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::companybucket"],
      "Condition": { "StringLike": {"s3:prefix": ["Development/*"] }
       }
    }
  ]
}
```

   f. Choose **Review Policy**. On the next page, enter a name in the **Name** field, and then choose **Create policy**.

3. Test the change to Alice's permissions:

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign in to the AWS Management Console.

   b. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   c. On the Amazon S3 console, verify that Alice can see the list of objects in the `Development/` folder in the bucket.

When the user chooses the /Development folder to see the list of objects in it, the Amazon S3 console sends the ListObjects request to Amazon S3 with the prefix /Development. Because the user is granted permission to see the object list with the prefix Development and delimiter /, Amazon S3 returns the list of objects with the key prefix Development/, and the console displays the list.

Step 5.2: Grant IAM user Alice permissions to get and put objects in the development folder

For Alice to get and put objects in the Development folder, she needs permission to call the s3:GetObject and s3:PutObject actions. The following policy statements grant these permissions, provided that the request includes the prefix parameter with a value of Development/.

```
{
    "Sid":"AllowUserToReadWriteObjectData",
    "Action":["s3:GetObject", "s3:PutObject"],
    "Effect":"Allow",
    "Resource":["arn:aws:s3:::companybucket/Development/*"]
 }
```

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Edit the inline policy that you created in the previous step.

   a. In the navigation pane on the left, choose **Users**.

   b. Choose the user name Alice.

   c. On the user details page, choose the **Permissions** tab and expand the **Inline Policies** section.

   d. Next to the name of the policy that you created in the previous step, choose **Edit Policy**.

   e. Copy the following policy and paste it into the policy text field, replacing the existing policy.

JSON

```
{
     "Version":"2012-10-17",
     "Statement":[
      {
         "Sid":"AllowListBucketIfSpecificPrefixIsIncludedInRequest",
         "Action":["s3:ListBucket"],
         "Effect":"Allow",
         "Resource":["arn:aws:s3:::companybucket"],
         "Condition":{
            "StringLike":{"s3:prefix":["Development/*"]
            }
         }
      },
      {
        "Sid":"AllowUserToReadWriteObjectDataInDevelopmentFolder",
        "Action":["s3:GetObject", "s3:PutObject"],
        "Effect":"Allow",
        "Resource":["arn:aws:s3:::companybucket/Development/*"]
      }
   ]
}
```

3. Test the updated policy:

   a. Using the IAM user sign-in link (see To provide a sign-in link for IAM users), sign into the AWS Management Console.

   b. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   c. On the Amazon S3 console, verify that Alice can now add an object and download an object in the `Development` folder.

Step 5.3: Explicitly deny IAM user Alice permissions to any other folders in the bucket

User Alice can now list the root-level content in the `companybucket` bucket. She can also get and put objects in the `Development` folder. If you really want to tighten the access permissions, you could explicitly deny Alice access to any other folders in the bucket. If there is any other policy (bucket policy or ACL) that grants Alice access to any other folders in the bucket, this explicit deny overrides those permissions.

You can add the following statement to the user Alice policy that requires all requests that Alice sends to Amazon S3 to include the `prefix` parameter, whose value can be either `Development/*` or an empty string.

```
{
   "Sid": "ExplicitlyDenyAnyRequestsForAllOtherFoldersExceptDevelopment",
   "Action": ["s3:ListBucket"],
   "Effect": "Deny",
   "Resource": ["arn:aws:s3:::companybucket"],
   "Condition":{  "StringNotLike": {"s3:prefix":["Development/*",""] },
                  "Null"         : {"s3:prefix":false }
    }
}
```

There are two conditional expressions in the `Condition` block. The result of these conditional expressions is combined by using the logical `AND`. If both conditions are true, the result of the combined condition is true. Because the `Effect` in this policy is `Deny`, when the `Condition` evaluates to true, users can't perform the specified `Action`.

- The `Null` conditional expression ensures that requests from Alice include the `prefix` parameter.

  The `prefix` parameter requires folder-like access. If you send a request without the `prefix` parameter, Amazon S3 returns all the object keys.

  If the request includes the `prefix` parameter with a null value, the expression evaluates to true, and so the entire `Condition` evaluates to true. You must allow an empty string as value of the `prefix` parameter. From the preceding discussion, recall that allowing the null string allows Alice to retrieve root-level bucket items as the console does in the preceding discussion. For more information, see Step 4.2: Enable users to list root-level content of a bucket.
- The `StringNotLike` conditional expression ensures that if the value of the `prefix` parameter is specified and is not `Development/*`, the request fails.

Follow the steps in the preceding section and again update the inline policy that you created for user Alice.

Copy the following policy and paste it into the policy text field, replacing the existing policy.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowListBucketIfSpecificPrefixIsIncludedInRequest",
         "Action":["s3:ListBucket"],
         "Effect":"Allow",
         "Resource":["arn:aws:s3:::companybucket"],
         "Condition":{
            "StringLike":{"s3:prefix":["Development/*"]
            }
         }
      },
      {
        "Sid":"AllowUserToReadWriteObjectDataInDevelopmentFolder",
        "Action":["s3:GetObject", "s3:PutObject"],
        "Effect":"Allow",
        "Resource":["arn:aws:s3:::companybucket/Development/*"]
      },
      {
         "Sid": "ExplicitlyDenyAnyRequestsForAllOtherFoldersExceptDevelopment",
         "Action": ["s3:ListBucket"],
         "Effect": "Deny",
         "Resource": ["arn:aws:s3:::companybucket"],
         "Condition":{  "StringNotLike": {"s3:prefix":["Development/*",""] },
                        "Null"         : {"s3:prefix":false }
          }
      }
   ]
}
```

Step 6: Grant IAM user Bob specific permissions

Now you want to grant Bob permission to the `Finance` folder. Follow the steps that you used earlier to grant permissions to Alice, but replace the `Development` folder with the `Finance` folder. For step-by-step instructions, see Step 5: Grant IAM user Alice specific permissions.

Step 7: Secure the private folder

In this example, you have only two users. You granted all the minimum required permissions at the group level and granted user-level permissions only when you really need to permissions at the individual user level. This approach helps minimize the effort of managing permissions. As the number of users increases, managing permissions can become cumbersome. For example, you don't want any of the users in this example to access the content of the `Private` folder. How do you ensure that you don't accidentally grant a user permission to the `Private` folder? You add a policy that explicitly denies access to the folder. An explicit deny overrides any other permissions.

To ensure that the `Private` folder remains private, you can add the following two deny statements to the group policy:

- Add the following statement to explicitly deny any action on resources in the `Private` folder (`companybucket/Private/*`).

```
{
  "Sid": "ExplictDenyAccessToPrivateFolderToEveryoneInTheGroup",
  "Action": ["s3:*"],
  "Effect": "Deny",
  "Resource":["arn:aws:s3:::companybucket/Private/*"]
}
```

- You also deny permission for the list objects action when the request specifies the `Private/` prefix. On the console, if Bob or Alice opens the `Private` folder, this policy causes Amazon S3 to return an error response.

```
{
  "Sid": "DenyListBucketOnPrivateFolder",
  "Action": ["s3:ListBucket"],
  "Effect": "Deny",
  "Resource": ["arn:aws:s3:::*"],
  "Condition":{
      "StringLike":{"s3:prefix":["Private/"]}
   }
}
```

Replace the `Consultants` group policy with an updated policy that includes the preceding deny statements. After the updated policy is applied, none of the users in the group can access the `Private` folder in your bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   Use your AWS account credentials, not the credentials of an IAM user, to sign in to the console.

2. Replace the existing `AllowGroupToSeeBucketListInTheConsole` managed policy that is attached to the `Consultants` group with the following policy. Remember to replace *`companybucket`* in the policy with the name of your bucket.

   For instructions, see Editing customer managed policies in the *IAM User Guide*. When following the instructions, make sure to follow the directions for applying your changes to all principal entities that the policy is attached to.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid":
 "AllowGroupToSeeBucketListAndAlsoAllowGetBucketLocationRequiredForListBucket",
      "Action": ["s3:ListAllMyBuckets", "s3:GetBucketLocation"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::*"]
    },
    {
      "Sid": "AllowRootLevelListingOfCompanyBucket",
      "Action": ["s3:ListBucket"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::companybucket"],
      "Condition":{
          "StringEquals":{"s3:prefix":[""]}
       }
    },
    {
      "Sid": "RequireFolderStyleList",
      "Action": ["s3:ListBucket"],
      "Effect": "Deny",
      "Resource": ["arn:aws:s3:::*"],
      "Condition":{
          "StringNotEquals":{"s3:delimiter":"/"}
       }
```

```
     },
    {
      "Sid": "ExplictDenyAccessToPrivateFolderToEveryoneInTheGroup",
      "Action": ["s3:*"],
      "Effect": "Deny",
      "Resource":["arn:aws:s3:::companybucket/Private/*"]
    },
    {
      "Sid": "DenyListBucketOnPrivateFolder",
      "Action": ["s3:ListBucket"],
      "Effect": "Deny",
      "Resource": ["arn:aws:s3:::*"],
      "Condition":{
          "StringLike":{"s3:prefix":["Private/"]}
       }
    }
  ]
}
```

Step 8: Clean up

To clean up, open the IAM Console and remove the users Alice and Bob. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.

To ensure that you aren't charged further for storage, you should also delete the objects and the bucket that you created for this exercise.

Identity-based policy examples for Amazon S3

This section shows several example AWS Identity and Access Management (IAM) identity-based policies for controlling access to Amazon S3. For example *bucket policies* (resource-based policies), see Bucket policies for Amazon S3. For information about IAM policy language, see Policies and permissions in Amazon S3.

The following example policies will work if you use them programmatically. However, to use them with the Amazon S3 console, you must grant additional permissions that are required by

the console. For information about using policies such as these with the Amazon S3 console, see Controlling access to a bucket with user policies.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Topics

- Allowing an IAM user access to one of your buckets
- Allowing each IAM user access to a folder in a bucket
- Allowing a group to have a shared folder in Amazon S3
- Allowing all your users to read objects in a portion of a bucket
- Allowing a partner to drop files into a specific portion of a bucket
- Restricting access to Amazon S3 buckets within a specific AWS account
- Restricting access to Amazon S3 buckets within your organizational unit
- Restricting access to Amazon S3 buckets within your organization
- Granting permission to retrieve the PublicAccessBlock configuration for an AWS account
- Restricting bucket creation to one Region

Allowing an IAM user access to one of your buckets

In this example, you want to grant an IAM user in your AWS account access to one of your buckets, *amzn-s3-demo-bucket1*, and allow the user to add, update, and delete objects.

In addition to granting the `s3:PutObject`, `s3:GetObject`, and `s3:DeleteObject` permissions to the user, the policy also grants the `s3:ListAllMyBuckets`, `s3:GetBucketLocation`, and `s3:ListBucket` permissions. These are the additional permissions required by the console. Also, the `s3:PutObjectAcl` and the `s3:GetObjectAcl` actions are required to be able to copy, cut, and paste objects in the console. For an example walkthrough that grants permissions to users and tests them using the console, see Controlling access to a bucket with user policies.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
```

```
            "Effect":"Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource":"*"
        },
        {
            "Effect":"Allow",
            "Action":["s3:ListBucket","s3:GetBucketLocation"],
            "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1"
        },
        {
            "Effect":"Allow",
            "Action":[
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:DeleteObject"
            ],
            "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/*"
        }
    ]
}
```

Allowing each IAM user access to a folder in a bucket

In this example, you want two IAM users, Mary and Carlos, to have access to your bucket, *amzn-s3-demo-bucket1*, so that they can add, update, and delete objects. However, you want to restrict each user's access to a single prefix (folder) in the bucket. You might create folders with names that match their usernames.

```
amzn-s3-demo-bucket1
   Mary/
   Carlos/
```

To grant each user access only to their folder, you can write a policy for each user and attach it individually. For example, you can attach the following policy to the user Mary to allow her specific Amazon S3 permissions on the *amzn-s3-demo-bucket1*/*Mary* folder.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/Mary/*"
      }
   ]
}
```

You can then attach a similar policy to the user Carlos, specifying the folder *`Carlos`* in the `Resource` value.

Instead of attaching policies to individual users, you can write a single policy that uses a policy variable and then attach the policy to a group. First, you must create a group and add both Mary and Carlos to the group. The following example policy allows a set of Amazon S3 permissions in the *`amzn-s3-demo-bucket1`*`/${aws:username}` folder. When the policy is evaluated, the policy variable `${aws:username}` is replaced by the requester's username. For example, if Mary sends a request to put an object, the operation is allowed only if Mary is uploading the object to the *`amzn-s3-demo-bucket1`*`/Mary` folder.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
```

```
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/${aws:username}/*"
      }
   ]
}
```

Note

When using policy variables, you must explicitly specify version 2012-10-17 in the policy. The default version of the IAM policy language, 2008-10-17, does not support policy variables.

If you want to test the preceding policy on the Amazon S3 console, the console requires additional permissions, as shown in the following policy. For information about how the console uses these permissions, see Controlling access to a bucket with user policies.

JSON

```
{
 "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGroupToSeeBucketListInTheConsole",
      "Action": [
       "s3:ListAllMyBuckets",
       "s3:GetBucketLocation"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::*"
    },
    {
      "Sid": "AllowRootLevelListingOfTheBucket",
      "Action": "s3:ListBucket",
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
```

```
      "Condition": {
            "StringEquals": {
                    "s3:prefix": [""], "s3:delimiter": ["/"]
                           }
                 }
    },
    {
      "Sid": "AllowListBucketOfASpecificUserPrefix",
      "Action": "s3:ListBucket",
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
      "Condition": {  "StringLike": {"s3:prefix": ["${aws:username}/*"] }
       }
    },
      {
     "Sid": "AllowUserSpecificActionsOnlyInTheSpecificUserPrefix",
         "Effect": "Allow",
         "Action": [
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/${aws:username}/*"
      }
  ]
}
```

Note

In the 2012-10-17 version of the policy, policy variables start with $. This change in syntax can potentially create a conflict if your object key (object name) includes a $.
To avoid this conflict, specify the $ character by using `${$}`. For example, to include the object key `my$file` in a policy, specify it as `my${$}file`.

Although IAM user names are friendly, human-readable identifiers, they aren't required to be globally unique. For example, if the user Carlos leaves the organization and another Carlos joins, then the new Carlos could access the old Carlos's information.

Instead of using usernames, you could create folders based on IAM user IDs. Each IAM user ID is unique. In this case, you must modify the preceding policy to use the `${aws:userid}` policy variable. For more information about user identifiers, see IAM Identifiers in the *IAM User Guide*.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/home/${aws:userid}/*"
      }
   ]
}
```

Allowing non-IAM users (mobile app users) access to folders in a bucket

Suppose that you want to develop a mobile app, a game that stores users' data in an S3 bucket. For each app user, you want to create a folder in your bucket. You also want to limit each user's access to their own folder. But you can't create folders before someone downloads your app and starts playing the game, because you don't have their user ID.

In this case, you can require users to sign in to your app by using public identity providers such as Login with Amazon, Facebook, or Google. After users have signed in to your app through one of these providers, they have a user ID that you can use to create user-specific folders at runtime.

You can then use web identity federation in AWS Security Token Service to integrate information from the identity provider with your app and to get temporary security credentials for each user. You can then create IAM policies that allow the app to access your bucket and perform such operations as creating user-specific folders and uploading data. For more information about web identity federation, see About web identity Federation in the *IAM User Guide*.

Allowing a group to have a shared folder in Amazon S3

Attaching the following policy to the group grants everybody in the group access to the following folder in Amazon S3: *amzn-s3-demo-bucket1*/share/marketing. Group members are allowed to access only the specific Amazon S3 permissions shown in the policy and only for objects in the specified folder.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/share/marketing/*"
      }
   ]
}
```

Allowing all your users to read objects in a portion of a bucket

In this example, you create a group named *AllUsers*, which contains all the IAM users that are owned by the AWS account. You then attach a policy that gives the group access to GetObject and GetObjectVersion, but only for objects in the *amzn-s3-demo-bucket1*/readonly folder.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
```

```
            "s3:GetObject",
            "s3:GetObjectVersion"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/readonly/*"
      }
   ]
}
```

Allowing a partner to drop files into a specific portion of a bucket

In this example, you create a group called *AnyCompany* that represents a partner company. You create an IAM user for the specific person or application at the partner company that needs access, and then you put the user in the group.

You then attach a policy that gives the group `PutObject` access to the following folder in a bucket:

amzn-s3-demo-bucket1/uploads/anycompany

You want to prevent the *AnyCompany* group from doing anything else with the bucket, so you add a statement that explicitly denies permission to any Amazon S3 actions except `PutObject` on any Amazon S3 resource in the AWS account.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"s3:PutObject",
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/uploads/anycompany/*"
      },
      {
         "Effect":"Deny",
         "Action":"s3:*",
         "NotResource":"arn:aws:s3:::amzn-s3-demo-bucket1/uploads/anycompany/*"
      }
   ]
}
```

Restricting access to Amazon S3 buckets within a specific AWS account

If you want to ensure that your Amazon S3 principals are accessing only the resources that are inside of a trusted AWS account, you can restrict access. For example, this identity-based IAM policy uses a Deny effect to block access to Amazon S3 actions, unless the Amazon S3 resource that's being accessed is in account *222222222222*. To prevent an IAM principal in an AWS account from accessing Amazon S3 objects outside of the account, attach the following IAM policy:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "DenyS3AccessOutsideMyBoundary",
      "Effect": "Deny",
      "Action": [
        "s3:*"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
            "222222222222"
          ]
        }
      }
    }
  ]
}
```

Note

This policy doesn't replace your existing IAM access controls, because it doesn't grant any access. Instead, this policy acts as an additional guardrail for your other IAM permissions, regardless of the permissions granted through other IAM policies.

Make sure to replace account ID *222222222222* in the policy with your own AWS account. To apply a policy to multiple accounts while still maintaining this restriction, replace the account ID with the `aws:PrincipalAccount` condition key. This condition requires that the principal and the resource must be in the same account.

Restricting access to Amazon S3 buckets within your organizational unit

If you have an organizational unit (OU) set up in AWS Organizations, you might want to restrict Amazon S3 bucket access to a specific part of your organization. In this example, we'll use the `aws:ResourceOrgPaths` key to restrict Amazon S3 bucket access to an OU in your organization. For this example, the OU ID is *ou-acroot-exampleou*. Make sure to replace this value in your own policy with your own OU IDs.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
     {
       "Sid": "DenyS3AccessOutsideMyBoundary",
       "Effect": "Deny",
       "Action": [
         "s3:*"
       ],
       "Resource": "*",
       "Condition": {
         "ForAllValues:StringNotLike": {
           "aws:ResourceOrgPaths": [
             "o-acorg/r-acroot/ou-acroot-exampleou/*"
           ]
         }
       }
     }
   ]
 }
```

> **Note**
>
> This policy doesn't grant any access. Instead, this policy acts as a backstop for your other IAM permissions, preventing your principals from accessing Amazon S3 objects outside of an OU-defined boundary.

The policy denies access to Amazon S3 actions unless the Amazon S3 object that's being accessed is in the *ou-acroot-exampleou* OU in your organization. The IAM policy condition requires `aws:ResourceOrgPaths`, a multivalued condition key, to contain any of the listed OU paths. The policy uses the `ForAllValues:StringNotLike` operator to compare the values of `aws:ResourceOrgPaths` to the listed OUs without case-sensitive matching.

Restricting access to Amazon S3 buckets within your organization

To restrict access to Amazon S3 objects within your organization, attach an IAM policy to the root of the organization, applying it to all accounts in your organization. To require your IAM principals to follow this rule, use a service-control policy (SCP). If you choose to use an SCP, make sure to thoroughly test the SCP before attaching the policy to the root of the organization.

In the following example policy, access is denied to Amazon S3 actions unless the Amazon S3 object that's being accessed is in the same organization as the IAM principal that is accessing it:

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
     {
       "Sid": "DenyS3AccessOutsideMyBoundary",
       "Effect": "Deny",
       "Action": [
         "s3:*"
       ],
       "Resource": "arn:aws:s3:::*/*",
       "Condition": {
         "StringNotEquals": {
           "aws:ResourceOrgID": "${aws:PrincipalOrgID}"
         }
       }
```

```
      }
    ]
 }
```

> **Note**
>
> This policy doesn't grant any access. Instead, this policy acts as a backstop for your other IAM permissions, preventing your principals from accessing any Amazon S3 objects outside of your organization. This policy also applies to Amazon S3 resources that are created after the policy is put into effect.

The IAM policy condition in this example requires `aws:ResourceOrgID` and `aws:PrincipalOrgID` to be equal to each other. With this requirement, the principal making the request and the resource being accessed must be in the same organization.

Granting permission to retrieve the PublicAccessBlock configuration for an AWS account

The following example identity-based policy grants the `s3:GetAccountPublicAccessBlock` permission to a user. For these permissions, you set the `Resource` value to `"*"`. For information about resource ARNs, see Policy resources for Amazon S3.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action":[
            "s3:GetAccountPublicAccessBlock"
         ],
         "Resource":[
            "*"
         ]
       }
    ]
}
```

Restricting bucket creation to one Region

Suppose that an AWS account administrator wants to grant its user (Dave) permission to create a bucket in the South America (São Paulo) Region only. The account administrator can attach the following user policy granting the `s3:CreateBucket` permission with a condition as shown. The key-value pair in the `Condition` block specifies the `s3:LocationConstraint` key and the `sa-east-1` Region as its value.

> **Note**
>
> In this example, the bucket owner is granting permission to one of its users, so either a bucket policy or a user policy can be used. This example shows a user policy.

For a list of Amazon S3 Regions, see Regions and Endpoints in the *AWS General Reference*.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "statement1",
         "Effect": "Allow",
         "Action": "s3:CreateBucket",
         "Resource": "arn:aws:s3:::*",
         "Condition": {
             "StringLike": {
                 "s3:LocationConstraint": "sa-east-1"
             }
         }
       }
    ]
}
```

Add explicit deny

The preceding policy restricts the user from creating a bucket in any other Region except `sa-east-1`. However, some other policy might grant this user permission to create buckets in another Region. For example, if the user belongs to a group, the group might have a policy attached to it

that allows all users in the group permission to create buckets in another Region. To ensure that the user doesn't get permission to create buckets in any other Region, you can add an explicit deny statement in the above policy.

The `Deny` statement uses the `StringNotLike` condition. That is, a create bucket request is denied if the location constraint is not `sa-east-1`. The explicit deny doesn't allow the user to create a bucket in any other Region, no matter what other permission the user gets. The following policy includes an explicit deny statement.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"statement1",
         "Effect":"Allow",
         "Action": "s3:CreateBucket",
         "Resource": "arn:aws:s3:::*",
         "Condition": {
             "StringLike": {
                 "s3:LocationConstraint": "sa-east-1"
             }
         }
       },
      {
         "Sid":"statement2",
         "Effect":"Deny",
         "Action": "s3:CreateBucket",
         "Resource": "arn:aws:s3:::*",
         "Condition": {
             "StringNotLike": {
                 "s3:LocationConstraint": "sa-east-1"
             }
         }
       }
    ]
}
```

Test the policy with the AWS CLI

You can test the policy using the following `create-bucket` AWS CLI command. This example uses the `bucketconfig.txt` file to specify the location constraint. Note the Windows file path. You need to update the bucket name and path as appropriate. You must provide user credentials using the `--profile` parameter. For more information about setting up and using the AWS CLI, see Developing with Amazon S3 using the AWS CLI in the *Amazon S3 API Reference*.

```
aws s3api create-bucket --bucket examplebucket --profile AccountADave --create-bucket-
configuration file://c:/Users/someUser/bucketconfig.txt
```

The `bucketconfig.txt` file specifies the configuration as follows.

```
{"LocationConstraint": "sa-east-1"}
```

Walkthroughs that use policies to manage access to your Amazon S3 resources

This topic provides the following introductory walkthrough examples for granting access to Amazon S3 resources. These examples use the AWS Management Console to create resources (buckets, objects, users) and grant them permissions. The examples then show you how to verify permissions using the command line tools, so you don't have to write any code. We provide commands using both the AWS Command Line Interface (AWS CLI) and the AWS Tools for Windows PowerShell.

- Example 1: Bucket owner granting its users bucket permissions

  The IAM users you create in your account have no permissions by default. In this exercise, you grant a user permission to perform bucket and object operations.
- Example 2: Bucket owner granting cross-account bucket permissions

  In this exercise, a bucket owner, Account A, grants cross-account permissions to another AWS account, Account B. Account B then delegates those permissions to users in its account.
- **Managing object permissions when the object and bucket owners are not the same**

  The example scenarios in this case are about a bucket owner granting object permissions to others, but not all objects in the bucket are owned by the bucket owner. What permissions does the bucket owner need, and how can it delegate those permissions?

  The AWS account that creates a bucket is called the *bucket owner*. The owner can grant other AWS accounts permission to upload objects, and the AWS accounts that create objects own them. The bucket owner has no permissions on those objects created by other AWS accounts. If the bucket owner writes a bucket policy granting access to objects, the policy doesn't apply to objects that are owned by other accounts.

  In this case, the object owner must first grant permissions to the bucket owner using an object ACL. The bucket owner can then delegate those object permissions to others, to users in its own account, or to another AWS account, as illustrated by the following examples.

  - Example 3: Bucket owner granting permissions to objects it does not own

    In this exercise, the bucket owner first gets permissions from the object owner. The bucket owner then delegates those permissions to users in its own account.
  - Example 4 - Bucket owner granting cross-account permission to objects it does not own

After receiving permissions from the object owner, the bucket owner can't delegate permission to other AWS accounts because cross-account delegation isn't supported (see Permission delegation). Instead, the bucket owner can create an IAM role with permissions to perform specific operations (such as get object) and allow another AWS account to assume that role. Anyone who assumes the role can then access objects. This example shows how a bucket owner can use an IAM role to enable this cross-account delegation.

Before you try the example walkthroughs

These examples use the AWS Management Console to create resources and grant permissions. To test permissions, the examples use the command line tools, AWS CLI, and AWS Tools for Windows PowerShell, so you don't need to write any code. To test permissions, you must set up one of these tools. For more information, see Setting up the tools for the walkthroughs.

In addition, when creating resources, these examples don't use root user credentials of an AWS account. Instead, you create an administrator user in these accounts to perform these tasks.

About using an administrator user to create resources and grant permissions

AWS Identity and Access Management (IAM) recommends not using the root user credentials of your AWS account to make requests. Instead, create an IAM user or role, grant them full access, and then use their credentials to make requests. We refer to this as an administrative user or role. For more information, go to AWS account root user credentials and IAM identities in the *AWS General Reference* and IAM Best Practices in the *IAM User Guide*.

All example walkthroughs in this section use the administrator user credentials. If you have not created an administrator user for your AWS account, the topics show you how.

To sign in to the AWS Management Console using the user credentials, you must use the IAM user sign-In URL. The IAM Console provides this URL for your AWS account. The topics show you how to get the URL.

Setting up the tools for the walkthroughs

The introductory examples (see Walkthroughs that use policies to manage access to your Amazon S3 resources) use the AWS Management Console to create resources and grant permissions. To test permissions, the examples use the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code. To test permissions, you must set up one of these tools.

To set up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:

   Install or update to the latest version of the AWS Command Line Interface

   Get started with the AWS Command Line Interface

2. Set the default profile.

   You store user credentials in the AWS CLI config file. Create a default profile in the config file using your AWS account credentials. For instructions on finding and editing your AWS CLI config file, see Configuration and credential file settings.

   ```
   [default]
   aws_access_key_id = access key ID
   aws_secret_access_key = secret access key
   region = us-west-2
   ```

3. Verify the setup by entering the following command at the command prompt. Both these commands don't provide credentials explicitly, so the credentials of the default profile are used.

   - Try the `help` command.

     ```
     aws help
     ```

   - To get a list of buckets on the configured account, use the `aws s3 ls` command.

     ```
     aws s3 ls
     ```

As you go through the walkthroughs, you will create users, and you will save user credentials in the config files by creating profiles, as the following example shows. These profiles have the names of `AccountAadmin` and `AccountBadmin`.

```
[profile AccountAadmin]
aws_access_key_id = User AccountAadmin access key ID
aws_secret_access_key = User AccountAadmin secret access key
region = us-west-2
```

```
[profile AccountBadmin]
aws_access_key_id = Account B access key ID
aws_secret_access_key = Account B secret access key
region = us-east-1
```

To run a command using these user credentials, you add the `--profile` parameter specifying the profile name. The following AWS CLI command retrieves a listing of objects in *examplebucket* and specifies the `AccountBadmin` profile.

```
aws s3 ls s3://examplebucket --profile AccountBadmin
```

Alternatively, you can configure one set of user credentials as the default profile by changing the `AWS_DEFAULT_PROFILE` environment variable from the command prompt. After you've done this, whenever you perform AWS CLI commands without the `--profile` parameter, the AWS CLI uses the profile you set in the environment variable as the default profile.

```
$ export AWS_DEFAULT_PROFILE=AccountAadmin
```

To set up AWS Tools for Windows PowerShell

1. Download and configure the AWS Tools for Windows PowerShell. For instructions, go to Installing the AWS Tools for Windows PowerShell in the *AWS Tools for PowerShell User Guide*.

   > **Note**
   >
   > To load the AWS Tools for Windows PowerShell module, you must enable PowerShell script execution. For more information, see Enable Script Execution in the *AWS Tools for PowerShell User Guide*.

2. For these walkthroughs, you specify AWS credentials per session using the `Set-AWSCredentials` command. The command saves the credentials to a persistent store (`-StoreAs` parameter).

   ```
   Set-AWSCredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -
   storeas string
   ```

3. Verify the setup.

- To retrieve a list of available commands that you can use for Amazon S3 operations, run the `Get-Command` command.

```
Get-Command -module awspowershell -noun s3* -StoredCredentials string
```

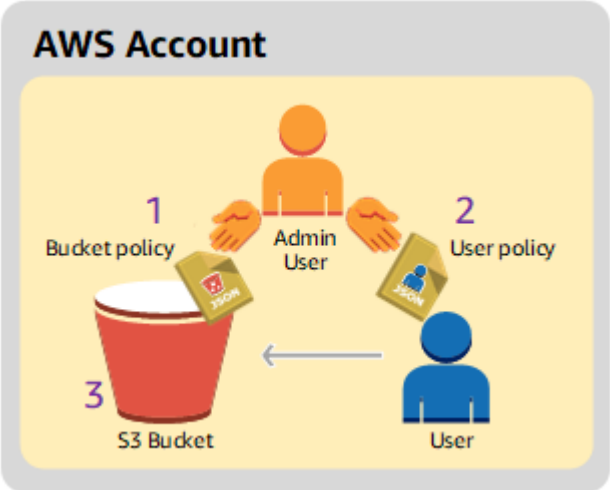
- To retrieve a list of objects in a bucket, run the `Get-S3Object` command.

```
Get-S3Object -BucketName bucketname -StoredCredentials string
```

For a list of commands, see AWS Tools for PowerShell Cmdlet Reference.

Now you're ready to try the walkthroughs. Follow the links provided at the beginning of each section.

Example 1: Bucket owner granting its users bucket permissions



> **Important**
>
> Granting permissions to IAM roles is a better practice than granting permissions to individual users.For more information about how to grant permissions to IAM roles, see Understanding cross-account permissions and using IAM roles.

Topics

- Preparing for the walkthrough
- Step 1: Create resources in Account A and grant permissions
- Step 2: Test permissions

In this walkthrough, an AWS account owns a bucket, and the account includes an IAM user By default, the user has no permissions. For the user to perform any tasks, the parent account must grant them permissions. The bucket owner and parent account are the same. Therefore, to grant the user permissions on the bucket, the AWS account can use a bucket policy, a user policy, or both. The account owner will grant some permissions using a bucket policy and other permissions using a user policy.

The following steps summarize the walkthrough:

1. Account administrator creates a bucket policy granting a set of permissions to the user.
2. Account administrator attaches a user policy to the user granting additional permissions.
3. User then tries permissions granted through both the bucket policy and the user policy.

For this example, you will need an AWS account. Instead of using the root user credentials of the account, you will create an administrator user (see About using an administrator user to create resources and grant permissions). We refer to the AWS account and the administrator user as shown in the following table.

Account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin

> **Note**
>
> The administrator user in this example is **AccountAadmin**, which refers to Account A, and not **AccountAdmin**.

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Preparing for the walkthrough

1. Make sure you have an AWS account and that it has a user with administrator privileges.

   a. Sign up for an AWS account, if needed. We refer to this account as Account A.

      i. Go to https://aws.amazon.com/s3 and choose **Create an AWS account**.

      ii. Follow the on-screen instructions.

      AWS will notify you by email when your account is active and available for you to use.

   b. In Account A, create an administrator user **`AccountAadmin`**. Using Account A credentials, sign in to the IAM console and do the following:

      i. Create user **`AccountAadmin`** and note the user security credentials.

      For instructions, see Creating an IAM user in your AWS account in the *IAM User Guide*.

      ii. Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access.

For instructions, see Managing IAM policies in the *IAM User Guide*.

iii. Note the **IAM user Sign-In URL** for **AccountAadmin**. You will need to use this URL when signing in to the AWS Management Console. For more information about where to find the sign-in URL, see Sign in to the AWS Management Console as an IAM user in *IAM User Guide*. Note the URL for each of the accounts.

2. Set up either the AWS CLI or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

   - If using the AWS CLI, create a profile, `AccountAadmin`, in the config file.
   - If using the AWS Tools for Windows PowerShell, make sure you store credentials for the session as `AccountAadmin`.

   For instructions, see Setting up the tools for the walkthroughs.

Step 1: Create resources in Account A and grant permissions

Using the credentials of user `AccountAadmin` in Account A, and the special IAM user sign-in URL, sign in to the AWS Management Console and do the following:

1. Create resources of a bucket and an IAM user

   a. In the Amazon S3 console, create a bucket. Note the AWS Region in which you created the bucket. For instructions, see Creating a general purpose bucket.

   b. In the IAM Console, do the following:

      i. Create a user named Dave.

      For step-by-step instructions, see Creating IAM users (console) in the *IAM User Guide*.

      ii. Note the `UserDave` credentials.

      iii. Note the Amazon Resource Name (ARN) for user Dave. In the IAM Console, select the user, and the **Summary** tab provides the user ARN.

2. Grant permissions.

   Because the bucket owner and the parent account to which the user belongs are the same, the AWS account can grant user permissions using a bucket policy, a user policy, or both. In this

example, you do both. If the object is also owned by the same account, the bucket owner can grant object permissions in the bucket policy (or an IAM policy).

a. In the Amazon S3 console, attach the following bucket policy to *awsexamplebucket1*.

The policy has two statements.

- The first statement grants Dave the bucket operation permissions `s3:GetBucketLocation` and `s3:ListBucket`.
- The second statement grants the `s3:GetObject` permission. Because Account A also owns the object, the account administrator is able to grant the `s3:GetObject` permission.

In the `Principal` statement, Dave is identified by his user ARN. For more information about policy elements, see Policies and permissions in Amazon S3.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Dave"
            },
            "Action": [
                "s3:GetBucketLocation",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::awsexamplebucket1"
            ]
        },
        {
            "Sid": "statement2",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Dave"
```

```
            },
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::awsexamplebucket1/*"
            ]
        }
    ]
}
```

b. Create an inline policy for the user Dave by using the following policy. The policy grants Dave the `s3:PutObject` permission. You need to update the policy by providing your bucket name.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "PermissionForObjectOperations",
         "Effect": "Allow",
         "Action": [
            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::awsexamplebucket1/*"
         ]
      }
   ]
}
```

For instructions, see Managing IAMpolicies in the *IAM User Guide*. Note you need to sign in to the console using Account A credentials.

Step 2: Test permissions

Using Dave's credentials, verify that the permissions work. You can use either of the following two procedures.

Test permissions using the AWS CLI

1. Update the AWS CLI config file by adding the following `UserDaveAccountA` profile. For more information, see Setting up the tools for the walkthroughs.

   ```
   [profile UserDaveAccountA]
   aws_access_key_id = access-key
   aws_secret_access_key = secret-access-key
   region = us-east-1
   ```

2. Verify that Dave can perform the operations as granted in the user policy. Upload a sample object using the following AWS CLI `put-object` command.

   The `--body` parameter in the command identifies the source file to upload. For example, if the file is in the root of the C: drive on a Windows machine, you specify `c:\HappyFace.jpg`. The `--key` parameter provides the key name for the object.

   ```
   aws s3api put-object --bucket awsexamplebucket1 --key HappyFace.jpg --
   body HappyFace.jpg --profile UserDaveAccountA
   ```

   Run the following AWS CLI command to get the object.

   ```
   aws s3api get-object --bucket awsexamplebucket1 --key HappyFace.jpg OutputFile.jpg
    --profile UserDaveAccountA
   ```

Test permissions using the AWS Tools for Windows PowerShell

1. Store Dave's credentials as `AccountADave`. You then use these credentials to PUT and GET an object.

   ```
   set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas
    AccountADave
   ```

2. Upload a sample object using the AWS Tools for Windows PowerShell `Write-S3Object` command using user Dave's stored credentials.

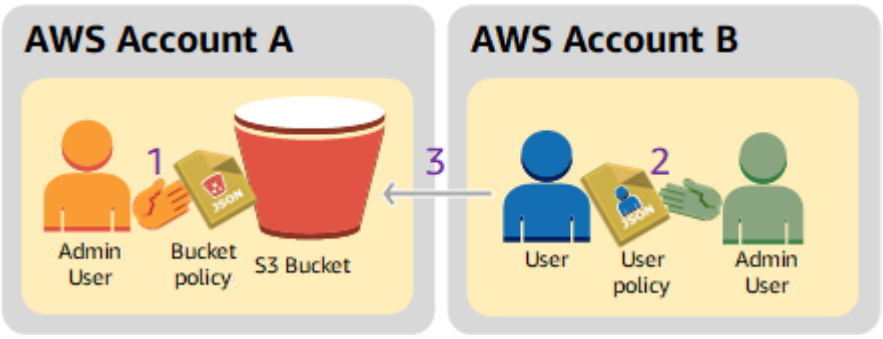
   ```
   Write-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file HappyFace.jpg
    -StoredCredentials AccountADave
   ```

Download the previously uploaded object.

```
Read-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file Output.jpg -
StoredCredentials AccountADave
```

Example 2: Bucket owner granting cross-account bucket permissions

> **Important**
>
> Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see Understanding cross-account permissions and using IAM roles.



Topics

- Preparing for the walkthrough
- Step 1: Do the Account A tasks
- Step 2: Do the Account B tasks
- Step 3: (Optional) Try explicit deny
- Step 4: Clean up

An AWS account—for example, Account A—can grant another AWS account, Account B, permission to access its resources such as buckets and objects. Account B can then delegate those permissions to users in its account. In this example scenario, a bucket owner grants cross-account permission to another account to perform specific bucket operations.

> **Note**
>
> Account A can also directly grant a user in Account B permissions using a bucket policy. However, the user will still need permission from the parent account, Account B, to which the user belongs, even if Account B doesn't have permissions from Account A. As long as the user has permission from both the resource owner and the parent account, the user will be able to access the resource.

The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy granting cross-account permissions to Account B to perform specific bucket operations.

   Note that administrator user in Account B will automatically inherit the permissions.
2. Account B administrator user attaches user policy to the user delegating the permissions it received from Account A.
3. User in Account B then verifies permissions by accessing an object in the bucket owned by Account A.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in them. In accordance with the IAM guidelines (see About using an administrator user to create resources and grant permissions), we don't use the root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Preparing for the walkthrough

1. Make sure you have two AWS accounts and that each account has one administrator user as shown in the table in the preceding section.

   a. Sign up for an AWS account, if needed.

   b. Using Account A credentials, sign in to the IAM console to create the administrator user:

      i. Create user **`AccountAadmin`** and note the security credentials. For instructions, see Creating an IAM user in Your AWS account in the *IAM User Guide*.

      ii. Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access. For instructions, see Working with Policies in the *IAM User Guide*.

   c. While you are in the IAM console, note the **IAM user Sign-In URL** on the **Dashboard**. All users in the account must use this URL when signing in to the AWS Management Console.

      For more information, see How Users Sign in to Your Account in *IAM User Guide*.

   d. Repeat the preceding step using Account B credentials and create administrator user **`AccountBadmin`**.

2. Set up either the AWS Command Line Interface (AWS CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

   - If using the AWS CLI, create two profiles, `AccountAadmin` and `AccountBadmin`, in the config file.
   - If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as `AccountAadmin` and `AccountBadmin`.

   For instructions, see Setting up the tools for the walkthroughs.

3. Save the administrator user credentials, also referred to as profiles. You can use the profile name instead of specifying credentials for each command you enter. For more information, see Setting up the tools for the walkthroughs.

   a. Add profiles in the AWS CLI credentials file for each of the administrator users, `AccountAadmin` and `AccountBadmin`, in the two accounts.

```
[AccountAadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
```

```
region = us-east-1

[AccountBadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
region = us-east-1
```

b. If you're using the AWS Tools for Windows PowerShell, run the following command.

```
set-awscredentials -AccessKey AcctA-access-key-ID -SecretKey AcctA-secret-
access-key -storeas AccountAadmin
set-awscredentials -AccessKey AcctB-access-key-ID -SecretKey AcctB-secret-
access-key -storeas AccountBadmin
```

Step 1: Do the Account A tasks

Step 1.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account A, first sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket

1. In the Amazon S3 console, create a bucket. This exercise assumes the bucket is created in the US East (N. Virginia) AWS Region and is named *amzn-s3-demo-bucket*.

   For instructions, see Creating a general purpose bucket.
2. Upload a sample object to the bucket.

   For instructions, go to Step 2: Upload an object to your bucket.

Step 1.3: Attach a bucket policy to grant cross-account permissions to Account B

The bucket policy grants the `s3:GetLifecycleConfiguration` and `s3:ListBucket` permissions to Account B. It's assumed that you're still signed in to the console using **AccountAadmin** user credentials.

1. Attach the following bucket policy to *amzn-s3-demo-bucket*. The policy grants Account B permission for the `s3:GetLifecycleConfiguration` and `s3:ListBucket` actions.

   For instructions, see Adding a bucket policy by using the Amazon S3 console.

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Example permissions",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::2222-2222-2222:root"
         },
         "Action": [
            "s3:GetLifecycleConfiguration",
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
         ]
      }
   ]
}
```

2. Verify that Account B (and thus its administrator user) can perform the operations.

   - Verify using the AWS CLI

   ```
   aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin
   aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --
   profile AccountBadmin
   ```

   - Verify using the AWS Tools for Windows PowerShell

   ```
   get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBadmin
   get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -
   StoredCredentials AccountBadmin
   ```

Step 2: Do the Account B tasks

Now the Account B administrator creates a user, Dave, and delegates the permissions received from Account A.

Step 2.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account B, first sign in to the AWS Management Console as **AccountBadmin** user.

Step 2.2: Create user Dave in Account B

In the IAM Console, create a user, **Dave**.

For instructions, see Creating IAM users (console) in the *IAM User Guide*.

Step 2.3: Delegate permissions to user Dave

Create an inline policy for the user Dave by using the following policy. You will need to update the policy by providing your bucket name.

It's assumed that you're signed in to the console using **AccountBadmin** user credentials.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "Example",
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
         ]
      }
   ]
}
```

For instructions, see Managing IAM policies in the *IAM User Guide*.

Step 2.4: Test permissions

Now Dave in Account B can list the contents of *amzn-s3-demo-bucket* owned by Account A. You can verify the permissions using either of the following procedures.

Test permissions using the AWS CLI

1. Add the UserDave profile to the AWS CLI config file. For more information about the config file, see Setting up the tools for the walkthroughs.

```
[profile UserDave]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. At the command prompt, enter the following AWS CLI command to verify Dave can now get an object list from the *amzn-s3-demo-bucket* owned by Account A. Note the command specifies the UserDave profile.

```
aws s3 ls s3://amzn-s3-demo-bucket --profile UserDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following get-bucket-lifecycle configuration—Amazon S3 returns permission denied.

```
aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --profile
 UserDave
```

Test permissions using AWS Tools for Windows PowerShell

1. Store Dave's credentials as AccountBDave.

```
set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas
 AccountBDave
```

2. Try the List Bucket command.

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following get-s3bucketlifecycleconfiguration—Amazon S3 returns permission denied.

```
get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -
StoredCredentials AccountBDave
```

Step 3: (Optional) Try explicit deny

You can have permissions granted by using an access control list (ACL), a bucket policy, or a user policy. But if there is an explicit deny set by either a bucket policy or a user policy, the explicit deny takes precedence over any other permissions. For testing, update the bucket policy and explicitly deny Account B the `s3:ListBucket` permission. The policy also grants `s3:ListBucket` permission. However, explicit deny takes precedence, and Account B or users in Account B will not be able to list objects in *amzn-s3-demo-bucket*.

1. Using credentials of user `AccountAadmin` in Account A, replace the bucket policy by the following.
2. Now if you try to get a bucket list using `AccountBadmin` credentials, access is denied.
   - Using the AWS CLI, run the following command:

     ```
     aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin
     ```

   - Using the AWS Tools for Windows PowerShell, run the following command:

     ```
     get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
     ```

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:
   - Sign in to the AWS Management Console (AWS Management Console) using Account A credentials, and do the following:
     - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket*. In the bucket **Properties**, delete the policy in the **Permissions** section.
     - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
     - In the IAM Console, remove the `AccountAadmin` user.

2. Sign in to the IAM Console using Account B credentials. Delete user `AccountBadmin`. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.

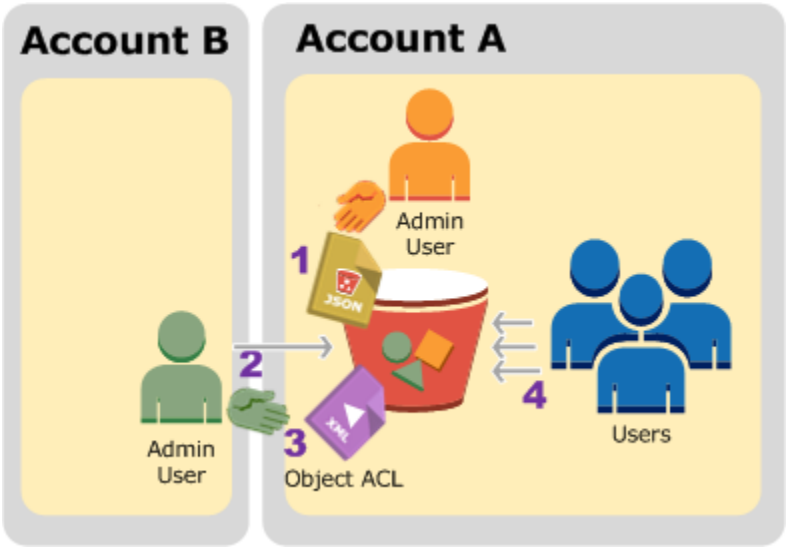
Example 3: Bucket owner granting permissions to objects it does not own

> **Important**
>
> Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see Understanding cross-account permissions and using IAM roles.

Topics

- Step 0: Preparing for the walkthrough
- Step 1: Do the Account A tasks
- Step 2: Do the Account B tasks
- Step 3: Test permissions
- Step 4: Clean up

The scenario for this example is that a bucket owner wants to grant permission to access objects, but the bucket owner doesn't own all objects in the bucket. For this example, the bucket owner is trying to grant permission to users in its own account.



A bucket owner can enable other AWS accounts to upload objects. By default, the bucket owner doesn't own objects written to a bucket by another AWS account. Objects are owned by the accounts that write them to an S3 bucket. If the bucket owner doesn't own objects in the bucket, the object owner must first grant permission to the bucket owner using an object access control list (ACL). Then, the bucket owner can grant permissions to an object that they don't own. For more information, see Amazon S3 bucket and object ownership.

If the bucket owner applies the bucket owner enforced setting for S3 Object Ownership for the bucket, the bucket owner will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts.

Note

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.
A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

In this example, we assume the bucket owner has not applied the bucket owner enforced setting for Object Ownership. The bucket owner delegates permission to users in its own account. The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy with two statements.
   - Allow cross-account permission to Account B to upload objects.
   - Allow a user in its own account to access objects in the bucket.
2. Account B administrator user uploads objects to the bucket owned by Account A.

3. Account B administrator updates the object ACL adding grant that gives the bucket owner full-control permission on the object.
4. User in Account A verifies by accessing objects in the bucket, regardless of who owns them.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In this walkthrough, you don't use the account root user credentials, according to the recommended IAM guidelines. For more information, see About using an administrator user to create resources and grant permissions. Instead, you create an administrator in each account and use those credentials in creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Step 0: Preparing for the walkthrough

1. Make sure that you have two AWS accounts and each account has one administrator as shown in the table in the preceding section.
   a. Sign up for an AWS account, if needed.
   b. Using Account A credentials, sign in to the IAM Console and do the following to create an administrator user:
      - Create user **`AccountAadmin`** and note the user's security credentials. For more information about adding users, see Creating an IAM user in your AWS account in the *IAM User Guide*.
      - Grant administrator permissions to **AccountAadmin** by attaching a user policy that gives full access. For instructions, see Managing IAM policies in the *IAM User Guide*.

- In the IAM Console **Dashboard**, note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see How users sign in to your account in *IAM User Guide*.

c. Repeat the preceding step using Account B credentials and create administrator user **`AccountBadmin`**.

2. Set up either the AWS CLI or the Tools for Windows PowerShell. Make sure that you save the administrator credentials as follows:

   - If using the AWS CLI, create two profiles, `AccountAadmin` and `AccountBadmin`, in the config file.
   - If using the Tools for Windows PowerShell, make sure that you store credentials for the session as `AccountAadmin` and `AccountBadmin`.

   For instructions, see Setting up the tools for the walkthroughs.

Step 1: Do the Account A tasks

Perform the following steps for Account A:

Step 1.1: Sign in to the console

Using the IAM user sign-in URL for Account A, sign in to the AWS Management Console as **`AccountAadmin`** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket and user, and add a bucket policy to grant user permissions

1. In the Amazon S3 console, create a bucket. This exercise assumes that the bucket is created in the US East (N. Virginia) AWS Region, and the name is *`amzn-s3-demo-bucket1`*.

   For instructions, see Creating a general purpose bucket.

2. In the IAM Console, create a user **`Dave`**.

   For step-by-step instructions, see Creating IAM users (console) in the *IAM User Guide*.

3. Note the user Dave credentials.
4. In the Amazon S3 console, attach the following bucket policy to *`amzn-s3-demo-bucket1`* bucket. For instructions, see Adding a bucket policy by using the Amazon S3 console. Follow the steps to add a bucket policy. For information about how to find account IDs, see Finding your AWS account ID.

The policy grants Account B the `s3:PutObject` and `s3:ListBucket` permissions. The policy also grants user `Dave` the `s3:GetObject` permission.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": [
                "s3:PutObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1/*",
                "arn:aws:s3:::amzn-s3-demo-bucket1"
            ]
        },
        {
            "Sid": "Statement3",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Dave"
            },
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ]
        }
    ]
}
```

Step 2: Do the Account B tasks

Now that Account B has permissions to perform operations on Account A's bucket, the Account B administrator does the following:

- Uploads an object to Account A's bucket
- Adds a grant in the object ACL to allow Account A, the bucket owner, full control

Using the AWS CLI

1. Using the `put-object` AWS CLI command, upload an object. The `--body` parameter in the command identifies the source file to upload. For example, if the file is on the `C:` drive of a Windows machine, specify `c:\HappyFace.jpg`. The `--key` parameter provides the key name for the object.

   ```
   aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --body
    HappyFace.jpg --profile AccountBadmin
   ```

2. Add a grant to the object ACL to allow the bucket owner full control of the object. For information about how to find a canonical user ID, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.

   ```
   aws s3api put-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --grant-
   full-control id="AccountA-CanonicalUserID" --profile AccountBadmin
   ```

Using the Tools for Windows PowerShell

1. Using the `Write-S3Object` command, upload an object.

   ```
   Write-S3Object -BucketName amzn-s3-demo-bucket1 -key HappyFace.jpg -file
    HappyFace.jpg -StoredCredentials AccountBadmin
   ```

2. Add a grant to the object ACL to allow the bucket owner full control of the object.

   ```
   Set-S3ACL -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -CannedACLName
    "bucket-owner-full-control" -StoredCreden
   ```

Step 3: Test permissions

Now verify that user Dave in Account A can access the object owned by Account B.

Using the AWS CLI

1. Add user Dave credentials to the AWS CLI config file and create a new profile, `UserDaveAccountA`. For more information, see Setting up the tools for the walkthroughs.

   ```
   [profile UserDaveAccountA]
   aws_access_key_id = access-key
   aws_secret_access_key = secret-access-key
   region = us-east-1
   ```

2. Run the `get-object` CLI command to download `HappyFace.jpg` and save it locally. You provide user Dave credentials by adding the `--profile` parameter.

   ```
   aws s3api get-object --bucket amzn-s3-demo-bucket1 --key
    HappyFace.jpg Outputfile.jpg --profile UserDaveAccountA
   ```

Using the Tools for Windows PowerShell

1. Store user Dave AWS credentials, as `UserDaveAccountA`, to persistent store.

   ```
   Set-AWSCredentials -AccessKey UserDave-AccessKey -SecretKey UserDave-
   SecretAccessKey -storeas UserDaveAccountA
   ```

2. Run the `Read-S3Object` command to download the `HappyFace.jpg` object and save it locally. You provide user Dave credentials by adding the `-StoredCredentials` parameter.

   ```
   Read-S3Object -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -file
    HappyFace.jpg  -StoredCredentials UserDaveAccountA
   ```

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:

   - Sign in to the AWS Management Console using Account A credentials, and do the following:

- In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
- If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
- In the IAM Console, remove the **AccountAadmin** user. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.

2. Sign in to the AWS Management Console using Account B credentials. In the IAM Console, delete the user **AccountBadmin**.

Example 4 - Bucket owner granting cross-account permission to objects it does not own

Topics

- Understanding cross-account permissions and using IAM roles
- Step 0: Preparing for the walkthrough
- Step 1: Do the account A tasks
- Step 2: Do the Account B tasks
- Step 3: Do the Account C tasks
- Step 4: Clean up
- Related resources

In this example scenario, you own a bucket and you have enabled other AWS accounts to upload objects. If you have applied the bucket owner enforced setting for S3 Object Ownership for the bucket, you will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by you, the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts. Suppose the bucket owner enforced setting for S3 Object Ownership is not enabled. That is, your bucket can have objects that other AWS accounts own.

Now, suppose as a bucket owner, you need to grant cross-account permission on objects, regardless of who the owner is, to a user in another account. For example, that user could be a billing application that needs to access object metadata. There are two core issues:

- The bucket owner has no permissions on those objects created by other AWS accounts. For the bucket owner to grant permissions on objects it doesn't own, the object owner must first grant permission to the bucket owner. The object owner is the AWS account that created the objects. The bucket owner can then delegate those permissions.
- The bucket owner account can delegate permissions to users in its own account (see Example 3: Bucket owner granting permissions to objects it does not own). However, the bucket owner account can't delegate permissions to other AWS accounts because cross-account delegation isn't supported.

In this scenario, the bucket owner can create an AWS Identity and Access Management (IAM) role with permission to access objects Then, the bucket owner can grant another AWS account permission to assume the role, temporarily enabling it to access objects in the bucket.

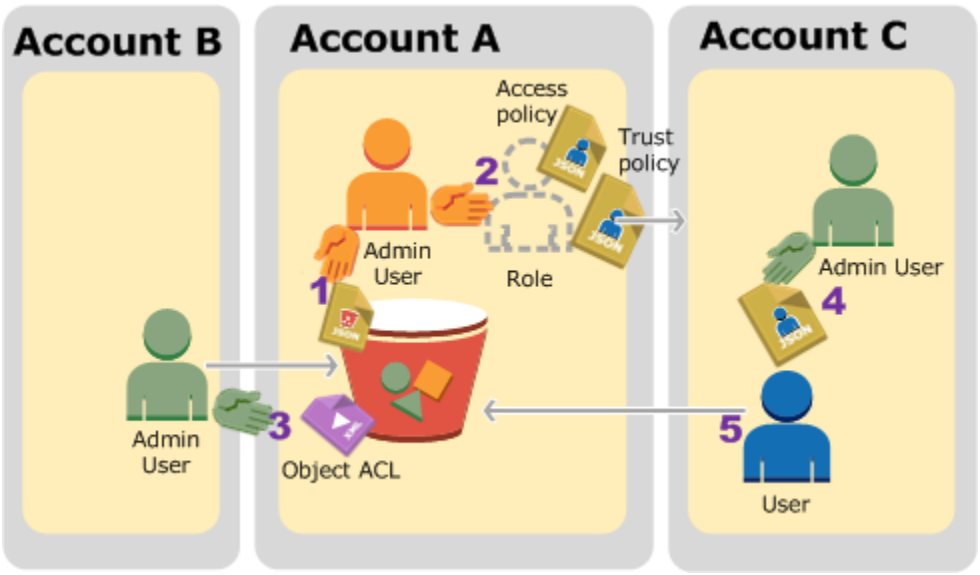
> **Note**
>
> S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.
> A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

Understanding cross-account permissions and using IAM roles

IAM roles enable several scenarios to delegate access to your resources, and cross-account access is one of the key scenarios. In this example, the bucket owner, Account A, uses an IAM role to temporarily delegate object access cross-account to users in another AWS account, Account C. Each IAM role that you create has the following two policies attached to it:

- A trust policy identifying another AWS account that can assume the role.

- An access policy defining what permissions—for example, `s3:GetObject`—are allowed when someone assumes the role. For a list of permissions you can specify in a policy, see Policy actions for Amazon S3.



The AWS account identified in the trust policy then grants its user permission to assume the role. The user can then do the following to access objects:

- Assume the role and, in response, get temporary security credentials.
- Using the temporary security credentials, access the objects in the bucket.

For more information about IAM roles, see IAM Roles in the *IAM User Guide*.

1. Account A administrator user attaches a bucket policy granting Account B conditional permission to upload objects.
2. Account A administrator creates an IAM role, establishing trust with Account C, so users in that account can access Account A. The access policy attached to the role limits what user in Account C can do when the user accesses Account A.
3. Account B administrator uploads an object to the bucket owned by Account A, granting full-control permission to the bucket owner.
4. Account C administrator creates a user and attaches a user policy that allows the user to assume the role.
5. User in Account C first assumes the role, which returns the user temporary security credentials. Using those temporary credentials, the user then accesses objects in the bucket.

The following is a summary of the walkthrough steps:

For this example, you need three accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In accordance with the IAM guidelines (see About using an administrator user to create resources and grant permissions), we don't use the AWS account root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin
3333-3333-3333	Account C	AccountCadmin

Step 0: Preparing for the walkthrough

> **Note**
>
> You might want to open a text editor, and write down some of the information as you go through the steps. In particular, you will need account IDs, canonical user IDs, IAM user Sign-in URLs for each account to connect to the console, and Amazon Resource Names (ARNs) of the IAM users, and roles.

1. Make sure that you have three AWS accounts and each account has one administrator user as shown in the table in the preceding section.

   a. Sign up for AWS accounts, as needed. We refer to these accounts as Account A, Account B, and Account C.

   b. Using Account A credentials, sign in to the IAM console and do the following to create an administrator user:

      - Create user **`AccountAadmin`** and note its security credentials. For more information about adding users, see Creating an IAM user in your AWS account in the *IAM User Guide*.
      - Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access. For instructions, see Managing IAM policies in the *IAM User Guide*.
      - In the IAM Console **Dashboard**, note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see Sign in to the AWS Management Console as an IAM user in the *IAM User Guide*.

   c. Repeat the preceding step to create administrator users in Account B and Account C.

2. For Account C, note the canonical user ID.

   When you create an IAM role in Account A, the trust policy grants Account C permission to assume the role by specifying the account ID. You can find account information as follows:

   a. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the Amazon S3 console.

   b. Choose the name of an Amazon S3 bucket to view the details about that bucket.

   c. Choose the **Permissions** tab and then choose **Access Control List**.

   d. In the **Access for your AWS account** section, in the **Account** column is a long identifier, such as `c1daexampleaaf850ea79cf0430f33d72579fd1611c97f7ded193374c0b163b6`. This is your canonical user ID.

3. When creating a bucket policy, you will need the following information. Note these values:

   - **Canonical user ID of Account A** – When the Account A administrator grants conditional upload object permission to the Account B administrator, the condition specifies the canonical user ID of the Account A user that must get full-control of the objects.

> **Note**
>
> The canonical user ID is the Amazon S3–only concept. It is a 64-character obfuscated version of the account ID.

- **User ARN for Account B administrator** – You can find the user ARN in the IAM Console.You must select the user and find the user's ARN in the **Summary** tab.

  In the bucket policy, you grant `AccountBadmin` permission to upload objects and you specify the user using the ARN. Here's an example ARN value:

  ```
  arn:aws:iam::AccountB-ID:user/AccountBadmin
  ```

4. Set up either the AWS Command Line Interface (CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:

   - If using the AWS CLI, create profiles, `AccountAadmin` and `AccountBadmin`, in the config file.
   - If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as `AccountAadmin` and `AccountBadmin`.

   For instructions, see Setting up the tools for the walkthroughs.

Step 1: Do the account A tasks

In this example, Account A is the bucket owner. So user AccountAadmin in Account A will do the following:

- Create a bucket.
- Attach a bucket policy that grants the Account B administrator permission to upload objects.
- Create an IAM role that grants Account C permission to assume the role so it can access objects in the bucket.

Step 1.1: Sign in to the AWS Management Console

Using the IAM user Sign-in URL for Account A, first sign in to the AWS Management Console as **`AccountAadmin`** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket and attach a bucket policy

In the Amazon S3 console, do the following:

1. Create a bucket. This exercise assumes the bucket name is *amzn-s3-demo-bucket1*.

   For instructions, see Creating a general purpose bucket.

2. Attach the following bucket policy. The policy grants conditional permission to the Account B administrator permission to upload objects.

   Update the policy by providing your own values for *amzn-s3-demo-bucket1*, *AccountB-ID*, and the *CanonicalUserId-of-AWSaccountA-BucketOwner*.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "111",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"
        },
        {
            "Sid": "112",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
            "Condition": {
                "StringNotEquals": {
                    "s3:x-amz-grant-full-control": "id=CanonicalUserId-of-
AWSaccountA-BucketOwner"
                }
            }
        }
```

```
    ]
}
```

Step 1.3: Create an IAM role to allow Account C cross-account access in Account A

In the IAM Console, create an IAM role (**examplerole**) that grants Account C permission to assume the role. Make sure that you are still signed in as the Account A administrator because the role must be created in Account A.

1. Before creating the role, prepare the managed policy that defines the permissions that the role requires. You attach this policy to the role in a later step.

   a. In the navigation pane on the left, choose **Policies** and then choose **Create Policy**.

   b. Next to **Create Your Own Policy**, choose **Select**.

   c. Enter **access-accountA-bucket** in the **Policy Name** field.

   d. Copy the following access policy and paste it into the **Policy Document** field. The access policy grants the role `s3:GetObject` permission so, when the Account C user assumes the role, it can only perform the `s3:GetObject` operation.

      JSON

      ```
      {
        "Version":"2012-10-17",
        "Statement": [
          {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"
          }
        ]
      }
      ```

   e. Choose **Create Policy**.

      The new policy appears in the list of managed policies.

2. In the navigation pane on the left, choose **Roles** and then choose **Create New Role**.

3. Under **Select Role Type**, select **Role for Cross-Account Access**, and then choose the **Select** button next to **Provide access between AWS accounts you own**.

4. Enter the Account C account ID.

   For this walkthrough, you don't need to require users to have multi-factor authentication (MFA) to assume the role, so leave that option unselected.

5. Choose **Next Step** to set the permissions that will be associated with the role.

6. Select the checkbox next to the **access-accountA-bucket** policy that you created, and then choose **Next Step**.

   The Review page appears so you can confirm the settings for the role before it's created. One very important item to note on this page is the link that you can send to your users who need to use this role. Users who use the link go straight to the **Switch Role** page with the Account ID and Role Name fields already filled in. You can also see this link later on the **Role Summary** page for any cross-account role.

7. Enter `examplerole` for the role name, and then choose **Next Step**.

8. After reviewing the role, choose **Create Role**.

   The `examplerole` role is displayed in the list of roles.

9. Choose the role name `examplerole`.

10. Select the **Trust Relationships** tab.

11. Choose **Show policy document** and verify the trust policy shown matches the following policy.

    The following trust policy establishes trust with Account C, by allowing it the `sts:AssumeRole` action. For more information, see AssumeRole in the *AWS Security Token Service API Reference*.

    JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": "sts:AssumeRole"
```

```
        }
    ]
}
```

12. Note the Amazon Resource Name (ARN) of the `examplerole` role that you created.

    Later in the following steps, you attach a user policy to allow an IAM user to assume this role, and you identify the role by the ARN value.

Step 2: Do the Account B tasks

The example bucket owned by Account A needs objects owned by other accounts. In this step, the Account B administrator uploads an object using the command line tools.

- Using the `put-object` AWS CLI command, upload an object to *amzn-s3-demo-bucket1*.

  ```
  aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --
  body HappyFace.jpg --grant-full-control id="canonicalUserId-ofTheBucketOwner" --
  profile AccountBadmin
  ```

  Note the following:

  - The `--Profile` parameter specifies the `AccountBadmin` profile, so the object is owned by Account B.
  - The parameter `grant-full-control` grants the bucket owner full-control permission on the object as required by the bucket policy.
  - The `--body` parameter identifies the source file to upload. For example, if the file is on the C: drive of a Windows computer, you specify `c:\HappyFace.jpg`.

Step 3: Do the Account C tasks

In the preceding steps, Account A has already created a role, `examplerole`, establishing trust with Account C. This role allows users in Account C to access Account A. In this step, the Account C administrator creates a user (Dave) and delegates him the `sts:AssumeRole` permission it received from Account A. This approach allows Dave to assume the `examplerole` and temporarily gain access to Account A. The access policy that Account A attached to the role limits what Dave can do when he accesses Account A—specifically, get objects in *amzn-s3-demo-bucket1*.

Step 3.1: Create a user in Account C and delegate permission to assume examplerole

1. Using the IAM user sign-in URL for Account C, first sign in to the AWS Management Console as **`AccountCadmin`** user.

2. In the IAM Console, create a user, Dave.

   For step-by-step instructions, see Creating IAM users (AWS Management Console) in the *IAM User Guide*.

3. Note the Dave credentials. Dave will need these credentials to assume the `examplerole` role.

4. Create an inline policy for the Dave IAM user to delegate the `sts:AssumeRole` permission to Dave on the `examplerole` role in Account A.

   a. In the navigation pane on the left, choose **Users**.

   b. Choose the user name **Dave**.

   c. On the user details page, select the **Permissions** tab and then expand the **Inline Policies** section.

   d. Choose **click here** (or **Create User Policy**).

   e. Choose **Custom Policy**, and then choose **Select**.

   f. Enter a name for the policy in the **Policy Name** field.

   g. Copy the following policy into the **Policy Document** field.

      You must update the policy by providing the *`AccountA-ID`*.

      JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": "arn:aws:iam::111122223333:role/examplerole"
        }
    ]
```

```
}
```

h. Choose **Apply Policy**.

5. Save Dave's credentials to the config file of the AWS CLI by adding another profile, `AccountCDave`.

```
[profile AccountCDave]
aws_access_key_id = UserDaveAccessKeyID
aws_secret_access_key = UserDaveSecretAccessKey
region = us-west-2
```

Step 3.2: Assume role (examplerole) and access objects

Now Dave can access objects in the bucket owned by Account A as follows:

- Dave first assumes the `examplerole` using his own credentials. This will return temporary credentials.
- Using the temporary credentials, Dave will then access objects in Account A's bucket.

1. At the command prompt, run the following AWS CLI `assume-role` command using the `AccountCDave` profile.

   You must update the ARN value in the command by providing the *`AccountA-ID`* where `examplerole` is defined.

```
aws sts assume-role --role-arn arn:aws:iam::AccountA-ID:role/examplerole --profile
 AccountCDave --role-session-name test
```

   In response, AWS Security Token Service (AWS STS) returns temporary security credentials (access key ID, secret access key, and a session token).

2. Save the temporary security credentials in the AWS CLI config file under the `TempCred` profile.

```
[profile TempCred]
aws_access_key_id = temp-access-key-ID
aws_secret_access_key = temp-secret-access-key
aws_session_token = session-token
region = us-west-2
```

3. At the command prompt, run the following AWS CLI command to access objects using the temporary credentials. For example, the command specifies the head-object API to retrieve object metadata for the `HappyFace.jpg` object.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --
key HappyFace.jpg SaveFileAs.jpg --profile TempCred
```

Because the access policy attached to `examplerole` allows the actions, Amazon S3 processes the request. You can try any other action on any other object in the bucket.

If you try any other action—for example, `get-object-acl`—you will get permission denied because the role isn't allowed that action.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --
profile TempCred
```

We used user Dave to assume the role and access the object using temporary credentials. It could also be an application in Account C that accesses objects in *amzn-s3-demo-bucket1*. The application can obtain temporary security credentials, and Account C can delegate the application permission to assume `examplerole`.

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:

   - Sign in to the AWS Management Console using Account A credentials, and do the following:

     - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
     - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
     - In the IAM Console, remove the `examplerole` you created in Account A. For step-by-step instructions, see Deleting an IAM user in the *IAM User Guide*.
     - In the IAM Console, remove the **AccountAadmin** user.

2. Sign in to the IAM Console by using Account B credentials. Delete the user **AccountBadmin**.

3. Sign in to the IAM Console by using Account C credentials. Delete **AccountCadmin** and the user Dave.

Using service-linked roles for Amazon S3 Storage Lens

To use Amazon S3 Storage Lens to collect and aggregate metrics across all your accounts in AWS Organizations, you must first ensure that S3 Storage Lens has trusted access enabled by the management account in your organization. S3 Storage Lens creates a service-linked role (SLR) to allow it to get the list of AWS accounts belonging to your organization. This list of accounts is used by S3 Storage Lens to collect metrics for S3 resources in all the member accounts when the S3 Storage Lens dashboard or configurations are created or updated.

Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up S3 Storage Lens easier because you don't have to add the necessary permissions manually. S3 Storage Lens defines the permissions of its service-linked roles, and unless defined otherwise, only S3 Storage Lens can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

You can delete this service-linked role only after first deleting the related resources. This protects your S3 Storage Lens resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon S3 Storage Lens

S3 Storage Lens uses the service-linked role named **AWSServiceRoleForS3StorageLens** – This enables access to AWS services and resources used or managed by S3 Storage Lens. This allows S3 Storage Lens to access AWS Organizations resources on your behalf.

The S3 Storage Lens service-linked role trusts the following service on your organization's storage:

- `storage-lens.s3.amazonaws.com`

The role permissions policy allows S3 Storage Lens to complete the following actions:

- `organizations:DescribeOrganization`

  `organizations:ListAccounts`

  `organizations:ListAWSServiceAccessForOrganization`

  `organizations:ListDelegatedAdministrators`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the *IAM User Guide*.

Creating a service-linked role for S3 Storage Lens

You don't need to manually create a service-linked role. When you complete one of the following tasks while signed into the AWS Organizations management or the delegate administrator accounts, S3 Storage Lens creates the service-linked role for you:

- Create an S3 Storage Lens dashboard configuration for your organization in the Amazon S3 console.
- PUT an S3 Storage Lens configuration for your organization using the REST API, AWS CLI and SDKs.

> **Note**
>
> S3 Storage Lens will support a maximum of five delegated administrators per organization.

If you delete this service-linked role, the preceding actions will re-create it as needed.

Example policy for S3 Storage Lens service-linked role

Example Permissions policy for the S3 Storage Lens service-linked role

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AwsOrgsAccess",
            "Effect": "Allow",
            "Action": [
                "organizations:DescribeOrganization",
                "organizations:ListAccounts",
                "organizations:ListAWSServiceAccessForOrganization",
                "organizations:ListDelegatedAdministrators"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

Editing a service-linked role for Amazon S3 Storage Lens

S3 Storage Lens doesn't allow you to edit the AWSServiceRoleForS3StorageLens service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Amazon S3 Storage Lens

If you no longer need to use the service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

> **Note**
>
> If the Amazon S3 Storage Lens service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the AWSServiceRoleForS3StorageLens you must delete all the organization level S3 Storage Lens configurations present in all AWS Regions using the AWS Organizations management or the delegate administrator accounts.

The resources are organization-level S3 Storage Lens configurations. Use S3 Storage Lens to clean up the resources and then use the IAM Console, CLI, REST API, or AWS SDK to delete the role.

In the REST API, AWS CLI, and SDKs, S3 Storage Lens configurations can be discovered using `ListStorageLensConfigurations` in all the Regions where your organization has created S3 Storage Lens configurations. Use the action `DeleteStorageLensConfiguration` to delete these configurations so that you can then delete the role.

> **Note**
>
> To delete the service-linked role, you must delete all the organization-level S3 Storage Lens configurations in all the Regions where they exist.

To delete Amazon S3 Storage Lens resources used by the AWSServiceRoleForS3StorageLens SLR

1. To get a list of your organization level configurations, you must use the `ListStorageLensConfigurations` in every Region that you have S3 Storage Lens configurations. This list can also be obtained from the Amazon S3 console.
2. Delete these configurations from the appropriate Regional endpoints by invoking the `DeleteStorageLensConfiguration` API call or by using the Amazon S3 console.

To manually delete the service-linked role using IAM

After you have deleted the configurations, delete the AWSServiceRoleForS3StorageLens SLR from the IAM Console or by invoking the IAM API `DeleteServiceLinkedRole`, or using the AWS CLI or AWS SDK. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Supported Regions for S3 Storage Lens service-linked roles

S3 Storage Lens supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see Amazon S3 Regions and Endpoints.

Troubleshooting Amazon S3 identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon S3 and IAM.

Topics

- I received an access denied error
- I am not authorized to perform an action in Amazon S3
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Amazon S3 resources
- Troubleshoot access denied (403 Forbidden) errors in Amazon S3

I received an access denied error

Verify that there is not an explicit `Deny` statement against the requester you are trying to grant permissions to in either the bucket policy or the identity-based policy.

For detailed information about troubleshooting access denied errors, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3.

I am not authorized to perform an action in Amazon S3

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `s3:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 s3:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *`my-example-widget`* resource by using the `s3:GetWidget` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Amazon S3.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Amazon S3. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my Amazon S3 resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon S3 supports these features, see How Amazon S3 works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

Troubleshoot access denied (403 Forbidden) errors in Amazon S3

Access denied (HTTP `403 Forbidden`) errors appear when AWS explicitly or implicitly denies an authorization request.

- An *explicit denial* occurs when a policy contains a `Deny` statement for the specific AWS action.
- An *implicit denial* occurs when there is no applicable `Deny` statement and also no applicable `Allow` statement.

Because an AWS Identity and Access Management (IAM) policy implicitly denies an IAM principal by default, the policy must explicitly allow the principal to perform an action. Otherwise, the policy implicitly denies access. For more information, see The difference between explicit and implicit denies in the *IAM User Guide*. For information about the policy evaluation logic that determines whether an access request is allowed or denied, see Policy evaluation logic in the *IAM User Guide*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

The following topics cover the most common causes of access denied errors in Amazon S3.

> **Note**
>
> For access denied (HTTP `403 Forbidden`) errors, Amazon S3 doesn't charge the bucket owner when the request is initiated outside of the bucket owner's individual AWS account or the bucket owner's AWS organization.

> **Note**
>
> If you're trying to troubleshoot a permissions issue, start with the the section called "Access denied message examples and how to troubleshoot them" section, then go to the ??? section. Also be sure to follow the guidance in the section called "Tips for checking permissions".

Access denied message examples and how to troubleshoot them

Amazon S3 now includes additional context in access denied (HTTP `403 Forbidden`) errors for requests made to resources within the same AWS account or same organization in AWS Organizations. This context includes the type of policy that denied access, the reason for denial, and information about the IAM user or role that requested access to the resource.

With this additional context, you can troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account or same-organization requests are available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions.

For explicit deny cases, the error message also includes the Amazon Resource Name (ARN) of the specific policy that denied the request. With this policy ARN, you can quickly identify the exact policy responsible for the denial and navigate directly to it to make the necessary changes. The error message includes the policy ARN for Service Control Policies (SCPs), resource control policies (RCPs), identity-based policies, session policies, and permissions boundaries.

Most access denied error messages appear in the format `User user-arn is not authorized to perform action on "resource-arn" because context`. In this example, *`user-arn`* is the Amazon Resource Name (ARN) of the user that doesn't receive access, *`action`* is the service action that the policy denies, and *`resource-arn`* is the ARN of the resource on which the policy acts. The *`context`* field represents additional context about the policy type that explains why the policy denied access.

When a policy explicitly denies access because the policy contains a `Deny` statement, then the access denied error message includes the phrase `with an explicit deny in a type policy`, along with the ARN of the specific policy that denied the request. When the policy implicitly denies access, then the access denied error message includes the phrase `because no type policy allows the action action`.

Important

- Enhanced access denied messages are returned only for same-account requests or for requests within the same organization in AWS Organizations. Cross-account requests outside of the same organization return a generic `Access Denied` message.

  For information about the policy evaluation logic that determines whether a cross-account access request is allowed or denied, see Cross-account policy evaluation logic in the *IAM User Guide*. For a walkthrough that shows how to grant cross-account access, see the section called "Granting cross-account permissions".
- For requests within the same organization in AWS Organizations:
  - Enhanced access denied messages aren't returned if a denial occurs because of a virtual private cloud (VPC) endpoint policy.
  - Enhanced access denied messages are provided whenever both the bucket owner and the caller account belong to the same organization in AWS Organizations. Although buckets configured with the S3 Object Ownership **Bucket owner preferred** or **Object writer** settings might contain objects owned by different accounts, object ownership doesn't affect enhanced access denied messages. Enhanced access denied messages

are returned for all object requests as long as the bucket owner and caller are in the same organization, regardless of who owns the specific object. For information about Object Ownership settings and configurations, see the section called "Controlling object ownership".

- Enhanced access denied error messages aren't returned for requests made to directory buckets. Directory bucket requests return a generic `Access Denied` message.
- If multiple policies of the same policy type deny an authorization request, the access denied error message doesn't specify the number of policies.
- For explicit deny cases, the error message includes the ARN of the specific policy that denied the request. This applies to Service Control Policies (SCPs), resource control policies (RCPs), identity-based policies, session policies, and permissions boundaries.
- If multiple policy types deny an authorization request, the error message includes only one of those policy types.
- If an access request is denied due to multiple reasons, the error message includes only one of the reasons for denial.

The following examples show the format for different types of access denied error messages and how to troubleshoot each type of message.

Access denied due to Blocked Encryption Type

To limit the server-side encryption types you can use in your general purpose buckets, you can choose to block SSE-C write requests by updating your default encryption configuration for your buckets. This bucket-level configuration blocks requests to upload objects that specify SSE-C. When SSE-C is blocked for a bucket, any `PutObject`, `CopyObject`, `PostObject`, or Multipart Upload or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 `AccessDenied` error.

This setting is a parameter on the `PutBucketEncryption` API and can also be updated using the S3 Console, AWS CLI, and AWS SDKs, if you have the `s3:PutEncryptionConfiguration` permission. Valid values are `SSE-C`, which blocks SSE-C encryption for the general purpose bucket, and `NONE`, which allows the use SSE-C for writes to the bucket.

For example, when access is denied for a `PutObject` request because the `BlockedEncryptionTypes` setting blocks write requests specifying SSE-C, you receive the following message:

```
An error occurred (AccessDenied) when calling the PutObject operation:
User: arn:aws:iam::123456789012:user/MaryMajor  is not
authorized to perform: s3:PutObject on resource:
"arn:aws:s3:::amzn-s3-demo-bucket1/object-name" because this
bucket has blocked upload requests that specify
Server Side Encryption with Customer provided keys (SSE-C).
Please specify a different server-side encryption type
```

For more information about this setting, see the section called “Blocking or unblocking SSE-C”.

Access denied due to a resource control policy – explicit denial

1. Check for an explicit `Deny` statement for the action in your resource control policies (RCPs). The error message includes the policy ARN, which you can use to identify and navigate directly to the policy that denied the request. For the following example, the action is `s3:GetObject`.
2. Update your RCP by removing the `Deny` statement. For more information, see Update a resource control policy (RCP) in the *AWS Organizations User Guide*.

```
An error occurred (AccessDenied) when calling the GetObject operation:
User: arn:aws:iam::777788889999:user/MaryMajor is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"
with an explicit deny in a resource control policy, with policy ARN:
arn:aws:organizations::777788889999:policy/o-exampleorgid/resource_control_policy/p-
examplepolicyid
```

Access denied due to a Service Control Policy – implicit denial

1. Check for a missing `Allow` statement for the action in your service control policies (SCPs). For the following example, the action is `s3:GetObject`.
2. Update your SCP by adding the `Allow` statement. For more information, see Updating an SCP in the *AWS Organizations User Guide*.

```
User: arn:aws:iam::777788889999:user/MaryMajor is not authorized to perform:
s3:GetObject because no service control policy allows the s3:GetObject action
```

Access denied due to a Service Control Policy – explicit denial

1. Check for an explicit `Deny` statement for the action in your Service Control Policies (SCPs). The error message includes the policy ARN, which you can use to identify and navigate directly to the policy that denied the request. For the following example, the action is `s3:GetObject`.
2. Update your SCP by changing the `Deny` statement to allow the user the necessary access. For an example of how you can do this, see Service control policy examples on GitHub. For more information about updating your SCP, see Updating an SCP in the *AWS Organizations User Guide*.

```
User: arn:aws:iam::777788889999:user/MaryMajor is not authorized to perform:
s3:GetObject with an explicit deny in a service control policy, with policy ARN:
arn:aws:organizations::777788889999:policy/o-exampleorgid/service_control_policy/p-
examplepolicyid
```

Access denied due to a VPC endpoint policy – implicit denial

1. Check for a missing `Allow` statement for the action in your virtual private cloud (VPC) endpoint policies. For the following example, the action is `s3:GetObject`.
2. Update your VPC endpoint policy by adding the `Allow` statement. For more information, see Update a VPC endpoint policy in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject because no VPC endpoint policy allows the s3:GetObject action
```

Access denied due to a VPC endpoint policy – explicit denial

1. Check for an explicit `Deny` statement for the action in your virtual private cloud (VPC) endpoint policies. For the following example, the action is `s3:GetObject`.
2. Update your VPC endpoint policy by changing the `Deny` statement to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in the section called "Example 7: Excluding principals from Deny statements". For more information about updating your VPC endpoint policy, see Update a VPC endpoint policy in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
```

```
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with
an explicit deny in a VPC endpoint policy
```

Access denied due to a permissions boundary – implicit denial

1. Check for a missing `Allow` statement for the action in your permissions boundary. For the following example, the action is `s3:GetObject`.
2. Update your permissions boundary by adding the `Allow` statement to your IAM policy. For more information, see Permissions boundaries for IAM entities and Editing IAM policies in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"
because no permissions boundary allows the s3:GetObject action
```

Access denied due to a permissions boundary – explicit denial

1. Check for an explicit `Deny` statement for the action in your permissions boundary. The error message includes the policy ARN, which you can use to identify and navigate directly to the policy that denied the request. For the following example, the action is `s3:GetObject`.
2. Update your permissions boundary by changing the `Deny` statement in your IAM policy to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in aws:PrincipalAccount in the *IAM User Guide*. For more information, see Permissions boundaries for IAM entities and Editing IAM policies in the *IAM User Guide*.

```
User: arn:aws:iam::777788889999:user/MaryMajor is not authorized to perform:
s3:GetObject with an explicit deny in a permissions boundary, with policy ARN:
arn:aws:iam::777788889999:policy/ExamplePermissionsBoundaryPolicy
```

Access denied due to session policies – implicit denial

1. Check for a missing `Allow` statement for the action in your session policies. For the following example, the action is `s3:GetObject`.
2. Update your session policy by adding the `Allow` statement. For more information, see Session policies and Editing IAM policies in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject because no session policy allows the s3:GetObject action
```

Access denied due to session policies – explicit denial

1. Check for an explicit `Deny` statement for the action in your session policies. The error message includes the policy ARN, which you can use to identify and navigate directly to the policy that denied the request. For the following example, the action is `s3:GetObject`.
2. Update your session policy by changing the `Deny` statement to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in the section called "Example 7: Excluding principals from Deny statements". For more information about updating your session policy, see Session policies and Editing IAM policies in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with
an explicit deny in a session policy, with policy ARN:
arn:aws:iam::123456789012:policy/ExampleSessionPolicy
```

Access denied due to resource-based policies – implicit denial

> **Note**
>
> *Resource-based policies* means policies such as bucket policies and access point policies.

1. Check for a missing `Allow` statement for the action in your resource-based policy. Also check whether the `IgnorePublicAcls` S3 Block Public Access setting is applied on the bucket, access point, or account level. For the following example, the action is `s3:GetObject`.
2. Update your policy by adding the `Allow` statement. For more information, see Resource-based policies and Editing IAM policies in the *IAM User Guide*.

   You might also need to adjust your `IgnorePublicAcls` block public access setting for the bucket, access point, or account. For more information, see the section called "Access denied due to Block Public Access settings" and the section called "Configuring bucket and access point settings".

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject because no resource-based policy allows the s3:GetObject action
```

Access denied due to resource-based policies – explicit denial

> **Note**
>
> *Resource-based policies* means policies such as bucket policies and access point policies.

1. Check for an explicit `Deny` statement for the action in your resource-based policy. Also check whether the `RestrictPublicBuckets` S3 Block Public Access setting is applied on the bucket, access point, or account level. For the following example, the action is `s3:GetObject`.
2. Update your policy by changing the `Deny` statement to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in the section called "Example 7: Excluding principals from Deny statements". For more information about updating your resource-based policy, see Resource-based policies and Editing IAM policies in the *IAM User Guide*.

   You might also need to adjust your `RestrictPublicBuckets` block public access setting for the bucket, access point, or account. For more information, see the section called "Access denied due to Block Public Access settings" and the section called "Configuring bucket and access point settings".

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with
an explicit deny in a resource-based policy
```

Access denied due to identity-based policies – implicit denial

1. Check for a missing `Allow` statement for the action in identity-based policies attached to the identity. For the following example, the action is `s3:GetObject` and the identity is the IAM user `MaryMajor`.
2. Update your policy by adding the `Allow` statement. For more information, see Identity-based policies and Editing IAM policies in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject because no identity-based policy allows the s3:GetObject action
```

Access denied due to identity-based policies – explicit denial

1. Check for an explicit `Deny` statement for the action in identity-based policies attached to the identity. The error message includes the policy ARN, which you can use to identify and navigate directly to the policy that denied the request. For the following example, the action is `s3:GetObject` and the identity is the IAM user `MaryMajor`.
2. Update your policy by changing the `Deny` statement to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in aws:PrincipalAccount in the *IAM User Guide*. For more information, see Identity-based policies and Editing IAM policies in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with
an explicit deny in an identity-based policy, with policy ARN:
arn:aws:iam::123456789012:policy/ExampleIdentityBasedPolicy
```

Access denied due to Block Public Access settings

The Amazon S3 Block Public Access feature provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. For more information about how Amazon S3 defines "public," see The meaning of "public".

By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, IAM user policies, object permissions, or access control lists (ACLs) to allow public access. S3 Block Public Access settings override these policies, permissions, and ACLs. Since April 2023, all Block Public Access settings are enabled by default for new buckets.

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an access point, bucket, or account setting.

The four settings provided by Amazon S3 Block Public Access are as follows:

- `BlockPublicAcls` – This setting applies to `PutBucketAcl`, `PutObjectAcl`, `PutObject`, `CreateBucket`, `CopyObject`, and `POST Object` requests. The `BlockPublicAcls` setting causes the following behavior:
  - `PutBucketAcl` and `PutObjectAcl` calls fail if the specified access control list (ACL) is public.
  - `PutObject` calls fail if the request includes a public ACL.
  - If this setting is applied to an account, then `CreateBucket` calls fail with an HTTP `400` (`Bad Request`) response if the request includes a public ACL.

  For example, when access is denied for a `CopyObject` request because of the `BlockPublicAcls` setting, you receive the following message:

  ```
  An error occurred (AccessDenied) when calling the CopyObject operation:
  User: arn:aws:sts::123456789012:user/MaryMajor is not authorized to
  perform: s3:CopyObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"
  because public ACLs are prevented by the BlockPublicAcls setting in S3 Block Public
   Access.
  ```

- `IgnorePublicAcls` – The `IgnorePublicAcls` setting causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. If your request's permission is granted only by a public ACL, then the `IgnorePublicAcls` setting rejects the request.

  Any denial resulting from the `IgnorePublicAcls` setting is implicit. For example, if `IgnorePublicAcls` denies a `GetObject` request because of a public ACL, you receive the following message:

  ```
  User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
  s3:GetObject because no resource-based policy allows the s3:GetObject action
  ```

- `BlockPublicPolicy` – This setting applies to `PutBucketPolicy` and `PutAccessPointPolicy` requests.

  Setting `BlockPublicPolicy` for a bucket causes Amazon S3 to reject calls to `PutBucketPolicy` if the specified bucket policy allows public access. This setting also causes Amazon S3 to reject calls to `PutAccessPointPolicy` for all of the bucket's same-account access points if the specified policy allows public access.

  Setting `BlockPublicPolicy` for an access point causes Amazon S3 to reject calls to `PutAccessPointPolicy` and `PutBucketPolicy` that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access.

  For example, when access is denied on a `PutBucketPolicy` request because of the `BlockPublicPolicy` setting, you receive the following message:

  ```
  An error occurred (AccessDenied) when calling the PutBucketPolicy operation:
  User: arn:aws:sts::123456789012:user/MaryMajor is not authorized to
  perform: s3:PutBucketPolicy on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-
  name"
  because public policies are prevented by the BlockPublicPolicy setting in S3 Block
   Public Access.
  ```

- `RestrictPublicBuckets` – The `RestrictPublicBuckets` setting restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and the access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket. This setting also rejects all anonymous (or unsigned) calls.

  Any denial resulting from the `RestrictPublicBuckets` setting is explicit. For example, if `RestrictPublicBuckets` denies a `GetObject` request because of a public bucket or access point policy, you receive the following message:

  ```
  User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:
  s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with
  an explicit deny in a resource-based policy
  ```

For more information about these settings, see the section called “Block public access settings”. To review and update these settings, see the section called “Configuring block public access”.

Access denied due to Requester Pays settings

If the Amazon S3 bucket you are trying to access has the Requester Pays feature enabled, you need to make sure you are passing the correct request parameters when making requests to that bucket. The Requester Pays feature in Amazon S3 allows the requester, instead of the bucket owner, to pay the data transfer and request costs for accessing objects in the bucket. When Requester Pays is enabled for a bucket, the bucket owner is not charged for requests made by other AWS accounts.

If you make a request to a Requester Pays-enabled bucket without passing the necessary parameters, you will receive an Access Denied (403 Forbidden) error. To access objects in a Requester Pays-enabled bucket, you must do the following:

1. When making requests using the AWS CLI, you must include the `--request-payer requester` parameter. For example, to copy an object with the key `object.txt` located in the `s3://amzn-s3-demo-bucket/` S3 bucket to a location on your local machine, you must also pass the parameter `--request-payer requester` if this bucket has Requester Pays enabled.

   ```
   aws s3 cp s3://amzn-s3-demo-bucket/object.txt /local/path \
   --request-payer requester
   ```

2. When making programmatic requests using an AWS SDK, set the `x-amz-request-payer` header to the value `requester`. For an example, see Downloading objects from Requester Pays buckets.
3. Make sure that the IAM user or role making the request has the necessary permissions to access the Requester Pays bucket, such as the `s3:GetObject` and `s3:ListBucket` permissions.

By including the `--request-payer requester` parameter or setting the `x-amz-request-payer` header, you are informing Amazon S3 that you, the requester, will pay the costs associated with accessing the objects in the Requester Pays-enabled bucket. This will prevent the Access Denied (403 Forbidden) error.

Bucket policies and IAM policies

Bucket-level operations

If there is no bucket policy in place, then the bucket implicitly allows requests from any AWS Identity and Access Management (IAM) identity in the bucket-owner's account. The bucket also implicitly denies requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they're

the AWS account root user) is implicitly denied from making any requests. For more information about this evaluation logic, see Determining whether a request is denied or allowed within an account in the *IAM User Guide*.

Object-level operations

If the object is owned by the bucket-owning account, the bucket policy and IAM user policy will function in the same way for object-level operations as they do for bucket-level operations. For example, if there is no bucket policy in place, then the bucket implicitly allows object requests from any IAM identity in the bucket-owner's account. The bucket also implicitly denies object requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they're the AWS account root user) is implicitly denied from making any object requests.

If the object is owned by an external account, then access to the object can be granted only through object access control lists (ACLs). The bucket policy and IAM user policy can still be used to deny object requests.

Therefore, to ensure that your bucket policy or IAM user policy isn't causing an Access Denied (403 Forbidden) error, make sure that the following requirements are met:

- For same-account access, there must not be an explicit `Deny` statement against the requester you are trying to grant permissions to, in either the bucket policy or the IAM user policy. If you want to grant permissions by using only the bucket policy and the IAM user policy, there must be at least one explicit `Allow` statement in one of these policies.
- For cross-account access, there must not be an explicit `Deny` statement against the requester that you're trying to grant permissions to, in either the bucket policy or the IAM user policy. To grant cross-account permissions by using only the bucket policy and IAM user policy, make sure that both the bucket policy and the IAM user policy of the requester include an explicit `Allow` statement.

> **Note**
>
> `Allow` statements in a bucket policy apply only to objects that are owned by the same bucket-owning account. However, `Deny` statements in a bucket policy apply to all objects regardless of object ownership.

To review or edit your bucket policy

> **Note**
>
> To view a bucket policy, you must have the `s3:GetBucketPolicy` permission. To edit a bucket policy, you must have the `s3:PutBucketPolicy` permission.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to view or edit a bucket policy for.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.

To review your bucket policy by using the AWS Command Line Interface (AWS CLI), use the get-bucket-policy command. To edit your bucket policy, use the put-bucket-policy command.

> **Note**
>
> If you get locked out of a bucket because of an incorrect bucket policy, sign in to the AWS Management Console by using your AWS account root user credentials. To regain access to your bucket, make sure to delete the incorrect bucket policy by using your AWS account root user credentials.

Tips for checking permissions

To check whether the requester has proper permissions to perform an Amazon S3 operation, try the following:

- Identify the requester. If it's an unsigned request, then it's an anonymous request without an IAM user policy. If it's a request that uses a presigned URL, then the user policy is the same as the one for the IAM user or role that signed the request.
- Verify that you're using the correct IAM user or role. You can verify your IAM user or role by checking the console navigation bar or by using the aws sts get-caller-identity command.

- Check the IAM policies that are related to the IAM user or role. You can use one of the following methods:
  - Test IAM policies with the IAM policy simulator.
  - Review the different IAM policy types.
- If needed, edit your IAM user policy.
- Review the following examples of policies that explicitly deny or allow access:
  - Explicit allow IAM user policy: IAM: Allows and denies access to multiple services programmatically and in the console
  - Explicit allow bucket policy: Granting permissions to multiple accounts to upload objects or set object ACLs for public access
  - Explicit deny IAM user policy: AWS: Denies access to AWS based on the requested AWS Region
  - Explicit deny bucket policy: Require SSE-KMS for all objects written to a bucket

Amazon S3 ACL settings

When checking your ACL settings, first review your Object Ownership setting to check whether ACLs are enabled on the bucket. Be aware that ACL permissions can be used only to grant permissions and can't be used to reject requests. ACLs also can't be used to grant access to requesters that are rejected by explicit denials in bucket policies or IAM user policies.

The Object Ownership setting is set to Bucket owner enforced

If the **Bucket owner enforced** setting is enabled, then ACL settings are unlikely to cause an Access Denied (403 Forbidden) error because this setting disables all ACLs that apply to bucket and objects. **Bucket owner enforced** is the default (and recommended) setting for Amazon S3 buckets.

The Object Ownership setting is set to Bucket owner preferred or Object writer

ACL permissions are still valid with the **Bucket owner preferred** setting or the **Object writer** setting. There are two kinds of ACLs: bucket ACLs and object ACLs. For the differences between these two types of ACLs, see Mapping of ACL permissions and access policy permissions.

Depending on the action of the rejected request, check the ACL permissions for your bucket or the object:

- If Amazon S3 rejected a `LIST`, PUT object, `GetBucketAcl`, or `PutBucketAcl` request, then review the ACL permissions for your bucket.

> **Note**
>
> You can't grant GET object permissions with bucket ACL settings.

- If Amazon S3 rejected a GET request on an S3 object, or a PutObjectAcl request, then review the ACL permissions for the object.

> **Important**
>
> If the account that owns the object is different from the account that owns the bucket, then access to the object isn't controlled by the bucket policy.

Troubleshooting an Access Denied (403 Forbidden) error from a GET object request during cross-account object ownership

Review the bucket's Object Ownership settings to determine the object owner. If you have access to the object ACLs, then you can also check the object owner's account. (To view the object owner's account, review the object ACL setting in the Amazon S3 console.) Alternatively, you can also make a `GetObjectAcl` request to find the object owner's canonical ID to verify the object owner account. By default, ACLs grant explicit allow permissions for GET requests to the object owner's account.

After you've confirmed that the object owner is different from the bucket owner, then depending on your use case and access level, choose one of the following methods to help address the Access Denied (403 Forbidden) error:

- **Disable ACLs (recommended)** – This method will apply to all objects and can be performed by the bucket owner. This method automatically gives the bucket owner ownership and full control over every object in the bucket. Before you implement this method, check the prerequisites for disabling ACLs. For information about how to set your bucket to **Bucket owner enforced** (recommended) mode, see Setting Object Ownership on an existing bucket.

> **Important**
>
> To prevent an Access Denied (403 Forbidden) error, be sure to migrate the ACL permissions to a bucket policy before you disable ACLs. For more information, see Bucket policy examples for migrating from ACL permissions.

- **Change the object owner to the bucket owner** – This method can be applied to individual objects, but only the object owner (or a user with the appropriate permissions) can change an object's ownership. Additional PUT costs might apply. (For more information, see Amazon S3 pricing.) This method grants the bucket owner full ownership of the object, allowing the bucket owner to control access to the object through a bucket policy.

  To change the object's ownership, do one of the following:

  - You (the bucket owner) can copy the object back to the bucket.
  - You can change the Object Ownership setting of the bucket to **Bucket owner preferred**. If versioning is disabled, the objects in the bucket are overwritten. If versioning is enabled, duplicate versions of the same object will appear in the bucket, which the bucket owner can set a lifecycle rule to expire. For instructions on how to change your Object Ownership setting, see Setting Object Ownership on an existing bucket.

    > **Note**
    >
    > When you update your Object Ownership setting to **Bucket owner preferred**, the setting is applied only to new objects that are uploaded to the bucket.

  - You can have the object owner upload the object again with the `bucket-owner-full-control` canned object ACL.

  > **Note**
  >
  > For cross-account uploads, you can also require the `bucket-owner-full-control` canned object ACL in your bucket policy. For an example bucket policy, see Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control.

- **Keep the object writer as the object owner** – This method doesn't change the object owner, but it does allow you to grant access to objects individually. To grant access to an object, you

must have the `PutObjectAcl` permission for the object. Then, to fix the Access Denied (403 Forbidden) error, add the requester as a grantee to access the object in the object's ACLs. For more information, see Configuring ACLs.

S3 Block Public Access settings

If the failed request involves public access or public policies, then check the S3 Block Public Access settings on your account, bucket, or access point. For more information about troubleshooting access denied errors related to S3 Block Public Access settings, see the section called "Access denied due to Block Public Access settings".

Amazon S3 encryption settings

Amazon S3 supports server-side encryption on your bucket. Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it.

By default, Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Amazon S3 also allows you to specify the server-side encryption method when uploading objects.

To review your bucket's server-side encryption status and encryption settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the bucket that you want to check the encryption settings for.
4. Choose the **Properties** tab.
5. Scroll down to the **Default encryption** section and view the **Encryption type** settings.

To check your encryption settings by using the AWS CLI, use the get-bucket-encryption command.

To check the encryption status of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.

3. From the **Buckets** list, choose the name of the bucket that contains the object.
4. From the **Objects** list, choose the name of the object that you want to add or change encryption for.

   The object's details page appears.
5. Scroll down to the **Server-side encryption settings** section to view the object's server-side encryption settings.

To check your object encryption status by using the AWS CLI, use the head-object command.

Encryption and permissions requirements

Amazon S3 supports three types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

Based on your encryption settings, make sure that the following permissions requirements are met:

- **SSE-S3** – No extra permissions are required.
- **SSE-KMS (with a customer managed key)** – To upload objects, the `kms:GenerateDataKey` permission on the AWS KMS key is required. To download objects and perform multipart uploads of objects, the `kms:Decrypt` permission on the KMS key is required.
- **SSE-KMS (with an AWS managed key)** – The requester must be from the same account that owns the `aws/s3` KMS key. The requester must also have the correct Amazon S3 permissions to access the object.
- **SSE-C (with a customer provided key)** – No additional permissions are required. You can configure the bucket policy to require and restrict server-side encryption with customer-provided encryption keys for objects in your bucket.

If the object is encrypted with a customer managed key, make sure that the KMS key policy allows you to perform the `kms:GenerateDataKey` or `kms:Decrypt` actions. For instructions on checking your KMS key policy, see Viewing a key policy in the *AWS Key Management Service Developer Guide*.

S3 Object Lock settings

If your bucket has S3 Object Lock enabled and the object is protected by a retention period or legal hold and you try to delete an object, Amazon S3 returns one of the following responses, depending on how you tried to delete the object:

- **Permanent DELETE request** – If you issued a permanent `DELETE` request (a request that specifies a version ID), Amazon S3 returns an Access Denied (`403 Forbidden`) error when you try to delete the object.
- **Simple DELETE request** – If you issued a simple `DELETE` request (a request that doesn't specify a version ID), Amazon S3 returns a `200 OK` response and inserts a delete marker in the bucket, and that marker becomes the current version of the object with a new ID.

To check whether the bucket has Object Lock enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to review.
4. Choose the **Properties** tab.
5. Scroll down to the **Object Lock** section. Verify whether the **Object Lock** setting is **Enabled** or **Disabled**.

To determine whether the object is protected by a retention period or legal hold, view the lock information for your object.

If the object is protected by a retention period or legal hold, check the following:

- If the object version is protected by the compliance retention mode, there is no way to permanently delete it. A permanent `DELETE` request from any requester, including the AWS account root user, will result in an Access Denied (403 Forbidden) error. Also, be aware that when you submit a `DELETE` request for an object that's protected by the compliance retention mode, Amazon S3 creates a delete marker for the object.
- If the object version is protected with governance retention mode and you have the `s3:BypassGovernanceRetention` permission, you can bypass the protection and permanently delete the version. For more information, see Bypassing governance mode.

- If the object version is protected by a legal hold, then a permanent `DELETE` request can result in an Access Denied (403 Forbidden) error. To permanently delete the object version, you must remove the legal hold on the object version. To remove a legal hold, you must have the `s3:PutObjectLegalHold` permission. For more information about removing a legal hold, see Configuring S3 Object Lock.

VPC endpoint policies

If you're accessing Amazon S3 by using a virtual private cloud (VPC) endpoint, make sure that the VPC endpoint policy isn't blocking you from accessing your Amazon S3 resources. By default, the VPC endpoint policy allows all requests to Amazon S3. You can also configure the VPC endpoint policy to restrict certain requests. For information about how to check your VPC endpoint policy, see the following resources:

- the section called “Access denied due to a VPC endpoint policy – implicit denial”
- the section called “Access denied due to a VPC endpoint policy – explicit denial”
- Control access to VPC endpoints by using endpoint policies in the *AWS PrivateLink Guide*

AWS Organizations policies

If your AWS account belongs to an organization, AWS Organizations policies can block you from accessing Amazon S3 resources. By default, AWS Organizations policies don't block any requests to Amazon S3. However, make sure that your AWS Organizations policies haven't been configured to block access to S3 buckets. For instructions on how to check your AWS Organizations policies, see the following resources:

- the section called “Access denied due to a Service Control Policy – implicit denial”
- the section called “Access denied due to a Service Control Policy – explicit denial”
- the section called “Access denied due to a resource control policy – explicit denial”
- Listing all policies in the *AWS Organizations User Guide*

Additionally, if you incorrectly configured your bucket policy for a member account to deny all users access to your S3 bucket, you can unlock the bucket by launching a privileged session for the member account in IAM. After you launch a privileged session, you can delete the misconfigured bucket policy to regain access to the bucket. For more information, see Perform a privileged task on an AWS Organizations member account in the *AWS Identity and Access Management User Guide*.

CloudFront distribution access

If you receive a Access Denied (403 Forbidden) error when trying to access your S3 static website through CloudFront, check these common issues:

- **Do you have the correct origin domain name format?**
  - Make sure you're using the S3 website endpoint format (bucket-name.s3-website-region.amazonaws.com) rather than the REST API endpoint
  - Verify that static website hosting is enabled on your bucket
- **Does your bucket policy allow CloudFront access?**
  - Ensure your bucket policy includes permissions for your CloudFront distribution's Origin Access Identity (OAI) or Origin Access Control (OAC)
  - Verify the policy includes the required s3:GetObject permissions

For additional troubleshooting steps and configurations, including error page setups and protocol settings, see Why do I get a "403 access denied" error when I use an Amazon S3 website endpoint as the origin of my CloudFront distribution? in the AWS re:Post Knowledge Center.

> **Note**
>
> This error is different from 403 errors you might receive when accessing S3 directly. For CloudFront-specific issues, make sure to check both your CloudFront distribution settings and S3 configurations.

Access point settings

If you receive an Access Denied (403 Forbidden) error while making requests through Amazon S3 access points, you might need to check the following:

- The configurations for your access points
- The IAM user policy that's used for your access points
- The bucket policy that's used to manage or configure your cross-account access points

Access point configurations and policies

- When you create an access point, you can choose to designate **Internet** or **VPC** as the network origin. If the network origin is set to VPC only, Amazon S3 will reject any requests made to the access point that don't originate from the specified VPC. To check the network origin of your access point, see Creating access points restricted to a virtual private cloud.
- With access points, you can also configure custom Block Public Access settings, which work similarly to the Block Public Access settings at the bucket or account level. To check your custom Block Public Access settings, see Managing public access to access points for general purpose buckets.
- To make successful requests to Amazon S3 by using access points, make sure that the requester has the necessary IAM permissions. For more information, see Configuring IAM policies for using access points.
- If the request involves cross-account access points, make sure that the bucket owner has updated the bucket policy to authorize requests from the access point. For more information, see Granting permissions for cross-account access points.

If the Access Denied (403 Forbidden) error still persists after checking all the items in this topic, retrieve your Amazon S3 request ID and contact Support for additional guidance.

Additional resources

For more guidance on Access Denied (403 Forbidden) errors you can check the following resources:

- How do I troubleshoot 403 Access Denied errors from Amazon S3? in the AWS re:Post Knowledge Center.
- Why am I getting a "403 Forbidden" error when I try to upload files in Amazon S3? in the AWS re:Post Knowledge Center.
- Why do I get an Access Denied error when I try to access an Amazon S3 resource in the same AWS account? in the AWS re:Post Knowledge Center.
- Why do I get an Access Denied error when I try to access an Amazon S3 bucket with public read access? in the AWS re:Post Knowledge Center.
- Why do I get a "signature mismatch" error when I try to use a presigned URL to upload an object to Amazon S3? in the AWS re:Post Knowledge Center.
- Why do I get an Access Denied error for ListObjectsV2 when I run the sync command on my Amazon S3 bucket? in the AWS re:Post Knowledge Center.

- Why do I get a "403 access denied" error when I use an Amazon S3 website endpoint as the origin of my CloudFront distribution? in the AWS re:Post Knowledge Center.

AWS managed policies for Amazon S3

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: AmazonS3FullAccess

You can attach the `AmazonS3FullAccess` policy to your IAM identities. This policy grants permissions that allow full access to Amazon S3.

To view the permissions for this policy, see AmazonS3FullAccess in the AWS Management Console.

AWS managed policy: AmazonS3ReadOnlyAccess

You can attach the `AmazonS3ReadOnlyAccess` policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon S3.

To view the permissions for this policy, see AmazonS3ReadOnlyAccess in the AWS Management Console.

AWS managed policy: AmazonS3ObjectLambdaExecutionRolePolicy

Provides AWS Lambda functions the required permissions to send data to S3 Object Lambda when requests are made to an S3 Object Lambda access point. Also grants Lambda permissions to write to Amazon CloudWatch logs.

To view the permissions for this policy, see AmazonS3ObjectLambdaExecutionRolePolicy in the AWS Management Console.

AWS managed policy: S3UnlockBucketPolicy

If you incorrectly configured your bucket policy for a member account to deny all users access to your S3 bucket, you can use this AWS managed policy (`S3UnlockBucketPolicy`) to unlock the bucket. For more information on how to remove a misconfigured bucket policy that denies all principals from accessing an Amazon S3 bucket, see Perform a privileged task on an AWS Organizations member account in the *AWS Identity and Access Management User Guide*.

Amazon S3 updates to AWS managed policies

View details about updates to AWS managed policies for Amazon S3 since this service began tracking these changes.

Change	Description	Date
Amazon S3 added `S3UnlockBucketPolicy`	Amazon S3 added a new AWS-managed policy called `S3UnlockBucketPolicy` to unlock a bucket and remove a misconfigured bucket policy that denies all principals from accessing an Amazon S3 bucket.	November 1, 2024
Amazon S3 added Describe permissions to `AmazonS3ReadOnlyAccess`	Amazon S3 added `s3:Describe*` permissions to `AmazonS3ReadOnlyAccess` .	August 11, 2023

Change	Description	Date
Amazon S3 added S3 Object Lambda permissions to `AmazonS3FullAccess` and `AmazonS3ReadOnlyAccess`	Amazon S3 updated the `AmazonS3FullAccess` and `AmazonS3ReadOnlyAccess` policies to include permissions for S3 Object Lambda.	September 27, 2021
Amazon S3 added `AmazonS3ObjectLambdaExecutionRolePolicy`	Amazon S3 added a new AWS-managed policy called `AmazonS3ObjectLambdaExecutionRolePolicy` that provides Lambda functions permissions to interact with S3 Object Lambda and write to CloudWatch logs.	August 18, 2021
Amazon S3 started tracking changes	Amazon S3 started tracking changes for its AWS managed policies.	August 18, 2021

Managing access to shared datasets with access points

Amazon S3 access points simplify data access for any AWS service or customer application that stores data in S3. Access points are named network endpoints that are attached to a data source such as a bucket, Amazon FSx for NetApp ONTAP volume, Amazon FSx for OpenZFS volume, or an Amazon S3 recovery point in AWS Backup. For information about working with buckets, see General purpose buckets overview. For information about working with FSx for NetApp ONTAP, see What is Amazon FSx for NetApp ONTAP in the *FSx for ONTAP User Guide*. For information about working with FSx for OpenZFS, see What is Amazon FSx for OpenZFS in the *FSx for OpenZFS User Guide*. An Amazon S3 recovery point (or backup) represents the content of an S3 bucket at a specified point in time, created by AWS Backup. For information about working with Amazon S3 backups, see Amazon S3 backups in the *AWS Backup Developer Guide*.

You can use access points to perform S3 object operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions and network controls that S3 applies for any request that is made through that access point. Each endpoint enforces a customized access point policy that allow you to control use by resource, user, or other conditions. If your access point is attached to a bucket the access point policy works in conjunction with the underlying bucket policy. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point.

> **Note**
>
> You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as deleting buckets or creating S3 Replication configurations. For a complete list of S3 operations that support access points, see Access point compatibility.

The topics in this section explain how to work with Amazon S3 access points. For topics on using access points with directory buckets see, Managing access to shared datasets in directory buckets with access points.

Topics

- Access points naming rules, restrictions, and limitations
- Referencing access points with ARNs, access point aliases, or virtual-hosted–style URIs
- Access point compatibility
- Configuring IAM policies for using access points
- Monitoring and logging access points
- Creating an access point
- Managing your Amazon S3 access points for general purpose buckets
- Using Amazon S3 access points for general purpose buckets
- Using tags with S3 Access Points for general purpose buckets

Access points naming rules, restrictions, and limitations

Access points are named network endpoints attached to a bucket, a volume on an Amazon FSx file system, or an Amazon S3 recovery point in AWS Backup that simplify managing data. When you create an access point you choose a name and the AWS Region to create it in. The following topics provide information about access point naming rules, restrictions and limitations.

Topics

- Naming rules for access points
- Restrictions and limitations for access points
- Restrictions and limitations for access points attached to a volume on an Amazon FSx file system
- Restrictions and limitations for access points attached to an Amazon S3 recovery point in AWS Backup

Naming rules for access points

When you create an access point, you choose its name and the AWS Region to create it in. Unlike general purpose buckets access point names do not need to be unique across AWS accounts or AWS Regions. The same AWS account may create access points with the same name in different AWS Regions or two different AWS accounts may use the same access point name. However, within a single AWS Region an AWS account may not have two identically named access points.

> **Note**
>
> If you choose to publicize your access point name, avoid including sensitive information in the access point name. Access point names are published in a publicly accessible database known as the Domain Name System (DNS).

Access point names must be DNS-compliant and must meet the following conditions:

- Must be unique within a single AWS account and AWS Region
- Must begin with a number or lowercase letter
- Must be between 3 and 50 characters long
- Can't begin or end with a hyphen (-)
- Can't contain underscores (_), uppercase letters, spaces, or periods (.)

- Can't end with the suffix `-s3alias` or `-ext-s3alias`. These suffixes are reserved for access point alias names. For more information, see Access point aliases.

Restrictions and limitations for access points

Amazon S3 access points have the following restrictions and limitations:

- Each access point is associated with exactly one bucket or FSx for OpenZFS volume. You must specify this when you create the access point. After you create an access point, you can't associate it with a different bucket or FSx for OpenZFS volume. However, you can delete an access point, and then create another one with the same name.
- After you create an access point, you can't change its virtual private cloud (VPC) configuration.
- Access point policies are limited to 20 KB in size.
- You can create a maximum of 10,000 access points per AWS account per AWS Region. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see AWS service quotas in the *AWS General Reference*.
- You can't use an access point as a destination for S3 Replication. For more information about replication, see Replicating objects within and across Regions.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- You can address access points only by using virtual-host-style URLs. For more information about virtual-host-style addressing, see Accessing an Amazon S3 general purpose bucket.
- API operations that control access point functionality (for example, `PutAccessPoint` and `GetAccessPointPolicy`) don't support cross-account calls.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST APIs. For more information about authenticating requests, see Authenticating Requests (AWS Signature Version 4) in the *Amazon Simple Storage Service API Reference*.
- Access points only support requests over HTTPS. Amazon S3 will automatically respond with an HTTP redirect for any requests made over HTTP, to upgrade the request to HTTPS.
- Access points don't support anonymous access.
- After you create an access point, you can't change its block public access settings.
- Cross-account access points don’t grant you access to data until you are granted permissions from the bucket owner. The bucket owner always retains ultimate control over access to the data

and must update the bucket policy to authorize requests from the cross-account access point. To view a bucket policy example, see Configuring IAM policies for using access points.

- In AWS Regions where you have more than 1,000 access points, you can't search for an access point by name in the Amazon S3 console.
- When you're viewing a cross-account access point in the Amazon S3 console, the **Access** column displays **Unknown**. The Amazon S3 console can't determine if public access is granted for the associated bucket and objects. Unless you require a public configuration for a specific use case, we recommend that you and the bucket owner block all public access to the access point and the bucket. For more information, see Blocking public access to your Amazon S3 storage.

Restrictions and limitations for access points attached to a volume on an Amazon FSx file system

The following are specific limitations when using access points attached to a volume on an Amazon FSx file system:

- When creating an access points you can only attach the access point to a volume on a Amazon FSx file systems that you own. You cannot attach to a volume owned by another AWS account.
- You cannot use the `CreateAccessPoint` API when creating and attaching an access point to a volume on a Amazon FSx file system. You must use the CreateAndAttachS3AccessPoint API.
- You can not turn off any block public access settings when creating or using an access point attached to a volume on an Amazon FSx file system.
- You can't list objects or use **Copy** or **Move** operations in the S3 console with access points attached to a volume on an Amazon FSx file system.
- `CopyObject` is supported for access points attached to an FSx for NetApp ONTAP or FSx for OpenZFS volume only if the source and destination are the same access point. For more information, about access point compatibility, see Access point compatibility.
- Multipart uploads are limited to 5GB.
- FSx for OpenZFS deployment type and storage class support varies by AWS Region. For more information, see Availability by AWS Region in the *OpenZFS User Guide*.

Restrictions and limitations for access points attached to an Amazon S3 recovery point in AWS Backup

The following are specific limitations when using access points attached to an S3 recovery point in AWS Backup:

- Access points for S3 recovery points are read-only. Write operations such as `PutObject`, `DeleteObject`, `CopyObject` and multipart uploads are not supported.
- Use the AWS Backup `CreateBackupAccessPoint` API or the AWS Backup console to create access points. The S3 `CreateAccessPoint` API is not supported.
- To delete these access points use the AWS Backup `DeleteBackupAccessPoint` API or the AWS Backup console.
- Each account can have up to 5 access points per recovery point, regardless of status.
- Access point names share the S3 access point namespace. A name used by a backup access point cannot be reused for a standard S3 access point in the same account and Region.
- For more information, see Backup access points in the *AWS Backup Developer Guide*.

Referencing access points with ARNs, access point aliases, or virtual-hosted–style URIs

After you create an access point you can use these endpoints to preform a number of operations. When referring to an access point you can use the Amazon Resource Names (ARNs), access point alias, or virtual-hosted–style URI.

Topics

- Access point ARNs
- Access point aliases
- Virtual-hosted–style URI

Access point ARNs

Access points have Amazon Resource Names (ARNs). Access point ARNs are similar to bucket ARNs, but they are explicitly typed and encode the access point's AWS Region and the AWS account ID of the access point's owner. For more information about ARNs, see Identify AWS resources with Amazon Resource Names (ARNs) in the *IAM User Guide*.

Access point ARNs use the following format:

```
arn:aws:s3:region:account-id:accesspoint/resource
```

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test` represents the access point named *test*, owned by account *123456789012* in the Region *us-west-2*.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/*` represents all access points under account *123456789012* in the Region *us-west-2*.

ARNs for objects accessed through an access point use the following format:

```
arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource
```

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01` represents the object *unit-01*, accessed through the access point named *test*, owned by account *123456789012* in the Region *us-west-2*.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/*` represents all objects for the access point named *test*, in account *123456789012* in the Region *us-west-2*.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01/finance/*` represents all objects under prefix *unit-01/finance/* for the access point named *test*, in account *123456789012* in the Region *us-west-2*.

Access point aliases

When you create an access point, Amazon S3 automatically generates an alias that you can use instead of an Amazon S3 bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for access point data plane operations. For a list of these operations, see Access point compatibility.

An access point alias name is created within the same namespace as an Amazon S3 bucket. This alias name is automatically generated and cannot be changed. An access point alias name meets all the requirements of a valid Amazon S3 bucket name and consists of the following parts:

ACCESS POINT NAME`-METADATA-s3alias` (for access points attached to an Amazon S3 bucket)

ACCESS POINT NAME`-METADATA-ext-s3alias` (for access points attached to an non-S3 bucket data source)

> **Note**
>
> The `-s3alias` and `-ext-s3alias` suffixes are reserved for access point alias names and can't be used for bucket or access point names. For more information about Amazon S3 bucket-naming rules, see General purpose bucket naming rules.

Access points aliases use cases and limitations

When adopting access points, you can use access point alias names without requiring extensive code changes.

When you create an access point, Amazon S3 automatically generates an access point alias name, as shown in the following example. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3control create-access-point --bucket amzn-s3-demo-bucket1 --name my-access-point
 --account-id 111122223333
{
    "AccessPointArn": "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
    "Alias": "my-access-point-aqfqprnstn7aefdfbarligizwgyfouse1a-s3alias"
}
```

You can use this access point alias name instead of an Amazon S3 bucket name in any data plane operation. For a list of these operations, see Access point compatibility.

The following AWS CLI example for the `get-object` command uses the bucket's access point alias to return information about the specified object. To run this command, replace the *`user input placeholders`* with your own information.

```
aws s3api get-object --bucket my-access-point-aqfqprnstn7aefdfbarligizwgyfouse1a-
s3alias --key dir/my_data.rtf my_data.rtf

{
    "AcceptRanges": "bytes",
    "LastModified": "2020-01-08T22:16:28+00:00",
    "ContentLength": 910,
    "ETag": "\"00751974dc146b76404bb7290f8f51bb\"",
    "VersionId": "null",
    "ContentType": "text/rtf",
    "Metadata": {}
```

```
}
```

Access point alias limitations

- Aliases cannot be configured by customers.
- Aliases cannot be deleted or modified or disabled on an access point.
- You can use this access point alias name instead of an Amazon S3 bucket name in some data plane operations. For a list of these operations, see Access points compatibility with S3 operations.
- You can't use an access point alias name for Amazon S3 control plane operations. For a list of Amazon S3 control plane operations, see Amazon S3 Control in the *Amazon Simple Storage Service API Reference*.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- Aliases cannot be used in AWS Identity and Access Management (IAM) policies.
- Aliases cannot be used as a logging destination for S3 server access logs.
- Aliases cannot be used as a logging destination for AWS CloudTrail logs.
- Amazon SageMaker AI GroundTruth does not support access point aliases.

Virtual-hosted–style URI

Access points only support virtual-host-style addressing. In a virtual-hosted–style URI, the access point name, AWS account, and AWS Region is part of the domain name in the URL. For more information about virtual hosting, see Virtual hosting of general purpose buckets.

Virtual-hosted–style URI for access points use the following format:

```
https://access-point-name-account-id.s3-accesspoint.region.amazonaws.com
```

Note

- If your access point name includes dash (-) characters, include the dashes in the URL and insert another dash before the account ID. For example, to use an access point named *finance-docs* owned by account *123456789012* in the Region *us-west-2*, the appropriate URL would be `https://finance-docs-123456789012.s3-accesspoint.us-west-2.amazonaws.com`.

- S3 access points don't support access through HTTP. Access points support only secure access through HTTPS.

Access point compatibility

You can use access points to access objects using the following subset of Amazon S3 APIs. All the operations listed below can accept either access point ARNs or access point aliases.

For examples of using access points to perform operations on objects, see Using Amazon S3 access points for general purpose buckets.

Access points compatibility with S3 operations

The following table is a partial list of Amazon S3 operations and if they are compatible with access points. All operations below are supported by access points using an S3 bucket as its data source, while only some operations are supported by access points using an FSx for ONTAP or FSx for OpenZFS volume or an S3 recovery point in AWS Backup as a data source.

For more information see, access point compatibility in the *FSx for ONTAP User Guide* or the *FSx for OpenZFS User Guide*.

S3 operation	Access point attached to an S3 bucket	Access point attached to an FSx for OpenZFS volume	Access point attached to an Amazon S3 recovery point in AWS Backup
AbortMultipartUpload	Supported	Supported	Not supported
CompleteMultipartUpload	Supported	Supported	Not supported
CopyObject (same-Region copies only)	Supported	Supported, if source and destination are the same access point	Not supported
CreateMultipartUpload	Supported	Supported	Not supported

UploadPartCopy (same-Region copies only)	Supported	Supported, if source and destination are the same access point	Not supported

Configuring IAM policies for using access points

Amazon S3 access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For an application or user to be able to access objects through an access point, both the access point and the underlying bucket or Amazon FSx file system must permit the request.

> **Important**
>
> Restrictions that you include in an access point policy apply only to requests made through that access point. Attaching an access point to a bucket does not change underlying resource's behavior. All existing operations against the bucket not made through your access point will continue to work as before.

When you're using IAM resource policies, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

Policy examples for access points

The following examples demonstrate how to create IAM policies to control requests made through an access point.

> **Note**
>
> Permissions granted in an access point policy are effective only if the underlying bucket also allows the same access. You can accomplish this in two ways:
>
> 1. **(Recommended)** Delegate access control from the bucket to the access point, as described in Delegating access control to access points.
> 2. Add the same permissions contained in the access point policy to the underlying bucket's policy. The Example 1 access point policy example demonstrates how to modify the underlying bucket policy to allow the necessary access.

Example 1 – Access point policy grant

The following access point policy grants IAM user *Jane* in account *123456789012* permissions to GET and PUT objects with the prefix *Jane/* through the access point *my-access-point* in account *123456789012*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Jane"
        },
        "Action": ["s3:GetObject", "s3:PutObject"],
        "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point/object/Jane/*"
    }]
}
```

Note

For the access point policy to effectively grant access to *Jane*, the underlying bucket must also allow the same access to *Jane*. You can delegate access control from the bucket to the access point as described in Delegating access control to access points. Or, you can add the following policy to the underlying bucket to grant the necessary permissions to Jane. Note that the `Resource` entry differs between the access point and bucket policies.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Jane"
        },
        "Action": ["s3:GetObject", "s3:PutObject"],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/Jane/*"
    }]
}
```

Example 2 – Access point policy with tag condition

The following access point policy grants IAM user *Mateo* in account *123456789012* permissions to GET objects through the access point *my-access-point* in the account *123456789012* that have the tag key *data* set with a value of *finance*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Mateo"
```

```
        },
        "Action": "s3:GetObject",
        "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-
point/object/*",
        "Condition": {
            "StringEquals": {
                "s3:ExistingObjectTag/data": "finance"
            }
        }
    }]
}
```

Example 3 – Access point policy that allows bucket listing

The following access point policy allows IAM user `Arnav` in the account *123456789012* permission to view the objects contained in the bucket underlying the access point *my-access-point* in the account *123456789012*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Arnav"
        },
        "Action": "s3:ListBucket",
        "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-
point"
    }]
}
```

Example 4 – Service control policy

The following service control policy requires all new access points to be created with a virtual private cloud (VPC) network origin. With this policy in place, users in your organization can't create new access points that are accessible from the internet.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Effect": "Deny",
        "Action": "s3:CreateAccessPoint",
        "Resource": "*",
        "Condition": {
            "StringNotEquals": {
                "s3:AccessPointNetworkOrigin": "VPC"
            }
        }
    }]
}
```

Example 5 – Bucket policy to limit S3 operations to VPC network origins

The following bucket policy limits access to all S3 object operations for the bucket *amzn-s3-demo-bucket* to access points with a VPC network origin.

> **Important**
>
> Before using a statement like the one shown in this example, make sure that you don't need to use features that aren't supported by access points, such as Cross-Region Replication.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:AbortMultipartUpload",
```

```
                "s3:BypassGovernanceRetention",
                "s3:DeleteObject",
                "s3:DeleteObjectTagging",
                "s3:DeleteObjectVersion",
                "s3:DeleteObjectVersionTagging",
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:GetObjectLegalHold",
                "s3:GetObjectRetention",
                "s3:GetObjectTagging",
                "s3:GetObjectVersion",
                "s3:GetObjectVersionAcl",
                "s3:GetObjectVersionTagging",
                "s3:ListMultipartUploadParts",
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:PutObjectLegalHold",
                "s3:PutObjectRetention",
                "s3:PutObjectTagging",
                "s3:PutObjectVersionAcl",
                "s3:PutObjectVersionTagging",
                "s3:RestoreObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringNotEquals": {
                    "s3:AccessPointNetworkOrigin": "VPC"
                }
            }
        }
    ]
}
```

Condition keys

S3 access points have condition keys that you can use in IAM policies to control access to your resources. The following condition keys represent only part of an IAM policy. For full policy examples, see Policy examples for access points, the section called “Delegating access control to access points”, and the section called “Granting permissions for cross-account access points”.

`s3:DataAccessPointArn`

This example shows a string that you can use to match on an access point ARN. The following example matches all access points for AWS account *123456789012* in Region *us-west-2*:

```
"Condition" : {
    "StringLike": {
        "s3:DataAccessPointArn": "arn:aws:s3:us-west-2:123456789012:accesspoint/*"
    }
}
```

`s3:DataAccessPointAccount`

This example shows a string operator that you can use to match on the account ID of the owner of an access point. The following example matches all access points that are owned by the AWS account *123456789012*.

```
"Condition" : {
    "StringEquals": {
        "s3:DataAccessPointAccount": "123456789012"
    }
}
```

`s3:AccessPointNetworkOrigin`

This example shows a string operator that you can use to match on the network origin, either `Internet` or VPC. The following example matches only access points with a VPC origin.

```
"Condition" : {
    "StringEquals": {
        "s3:AccessPointNetworkOrigin": "VPC"
    }
}
```

For more information about using condition keys with Amazon S3, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Delegating access control to access points

You can delegate access control for a bucket to the bucket's access points. The following example bucket policy allows full access to all access points that are owned by the bucket owner's account. Thus, all access to this bucket is controlled by the policies attached to its access points. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket.

Example 6 – Bucket policy that delegates access control to access points

JSON

```
{
    "Version":"2012-10-17",
    "Statement" : [
    {
        "Effect": "Allow",
        "Principal" : { "AWS": "*" },
        "Action" : "*",
        "Resource" : [ "arn:aws:s3:::amzn-s3-demo-bucket", "arn:aws:s3:::amzn-s3-
demo-bucket/*"],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointAccount" : "111122223333" }
        }
    }]
}
```

Granting permissions for cross-account access points

To create an access point to a bucket that's owned by another account, you must first create the access point by specifying the bucket name and account owner ID. Then, the bucket owner must update the bucket policy to authorize requests from the access point. Creating an access point is similar to creating a DNS CNAME in that the access point doesn't provide access to the bucket contents. All bucket access is controlled by the bucket policy. The following example bucket policy allows `GET` and `LIST` requests on the bucket from an access point that's owned by a trusted AWS account.

Replace *`Bucket ARN`* with the ARN of the bucket.

Example 7 – Bucket policy delegating permissions to another AWS account

JSON

```
{
    "Version":"2012-10-17",
    "Statement" : [
    {
        "Effect": "Allow",
        "Principal" : { "AWS": "*" },
        "Action" : ["s3:GetObject","s3:ListBucket"],
        "Resource" : ["arn:aws:s3:::amzn-s3-demo-bucket", "arn:aws:s3:::amzn-s3-
demo-bucket/*"],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointAccount" : "Access point
 owner's account ID" }
        }
    }]
}
```

Note

Cross-account access points are only available for access points attached to S3 buckets. You cannot attach an access point to a volume on an Amazon FSx file system owned by another AWS account.

Monitoring and logging access points

Amazon S3 logs requests made through access points and requests made to the API operations that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`. To monitor and manage usage patterns, you can also configure Amazon CloudWatch Logs request metrics for access points.

Topics

- CloudWatch request metrics
- AWS CloudTrail logs for requests made through access points

CloudWatch request metrics

To understand and improve the performance of applications that are using access points, you can use CloudWatch for Amazon S3 request metrics. Request metrics help you monitor Amazon S3 requests to quickly identify and act on operational issues.

By default, request metrics are available at the bucket level. However, you can define a filter for request metrics using a shared prefix, object tags, or an access point. When you create an access point filter, the request metrics configuration includes requests to the access point that you specify. You can receive metrics, set alarms, and access dashboards to view real-time operations performed through this access point.

You must opt in to request metrics by configuring them in the console or by using the Amazon S3 API. Request metrics are available at 1-minute intervals after some latency for processing. Request metrics are billed at the same rate as CloudWatch custom metrics. For more information, see Amazon CloudWatch pricing.

To create a request metrics configuration that filters by access point, see Creating a metrics configuration that filters by prefix, object tag, or access point.

AWS CloudTrail logs for requests made through access points

You can log requests made through access points and requests made to the APIs that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`, by using server access logging and AWS CloudTrail.

CloudTrail log entries for requests made through access points include the access point ARN in the `resources` section of the log.

For example, suppose you have the following configuration:

- A bucket named *amzn-s3-demo-bucket1* in Region *us-west-2* that contains an object named *my-image.jpg*
- An access point named *my-bucket-ap* that is associated with *amzn-s3-demo-bucket1*
- An AWS account ID of *123456789012*

The following example shows the `resources` section of a CloudTrail log entry for the preceding configuration:

```
"resources": [
        {"type": "AWS::S3::Object",
            "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1/my-image.jpg"
        },
        {"accountId": "123456789012",
            "type": "AWS::S3::Bucket",
            "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1"
        },
        {"accountId": "123456789012",
            "type": "AWS::S3::AccessPoint",
            "ARN": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-bucket-ap"
        }
    ]
```

If you are using an access point attached to a volume on an Amazon FSx file system, the `resources` section of a CloudTrail log entry will look different. For example:

```
"resources": [
        {
            "accountId": "123456789012",
            "type": "AWS::FSx::Volume",
            "ARN": "arn:aws:fsx:us-east-1:123456789012:volume/fs-0123456789abcdef9/
fsvol-01234567891112223"
        }
    ]
```

If you are using an access point attached to an S3 recovery point in AWS Backup, data plane requests (such as `GetObject` and `ListObjectsV2`) are logged in CloudTrail the same way as requests through standard S3 access points. For example:

```
"resources": [
        {
            "accountId": "123456789012",
            "type": "AWS::Backup::BackupAccessPoint",
            "ARN": "arn:aws:backup:us-east-1:123456789012:accesspoint/my-access-point"
        },
        {
            "type": "AWS::S3::Object",
            "ARN": "arn:aws:s3:us-east-1:123456789012:accesspoint/my-access-point/
object/path/to/my-file.txt"
        },
        {
```

```
            "accountId": "123456789012",
            "type": "AWS::S3::AccessPoint",
            "ARN": "arn:aws:s3:us-east-1:123456789012:accesspoint/my-access-point"
        }
    ]
```

Control plane operations for backup access points (such as `CreateBackupAccessPoint` and `DeleteBackupAccessPoint`) are logged as AWS Backup events. For more information, see Monitoring AWS Backup in the *AWS Backup Developer Guide*.

For more information about S3 Server Access Logs, see Logging requests with server access logging. For more information about AWS CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

Creating an access point

You can create S3 access points by using the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. Access points are named network endpoints that are attached to a data source such as a bucket, Amazon FSx for ONTAP volume, or Amazon FSx for OpenZFS volume.

By default, you can create up to 10,000 access points per Region for each of your AWS accounts. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see AWS Service Quotas in the *AWS General Reference*.

Topics

- Creating access points with S3 buckets
- Creating access points with Amazon FSx
- Creating access points with AWS Backup
- Creating access points restricted to a virtual private cloud
- Managing public access to access points for general purpose buckets

Creating access points with S3 buckets

An access point is associated with exactly one Amazon S3 general purpose bucket. If you want to use a bucket in your AWS account, you must first create a bucket. For more information about creating buckets, see Creating, configuring, and working with Amazon S3 general purpose buckets.

You can also create a cross-account access point that's associated with a bucket in another AWS account, as long as you know the bucket name and the bucket owner's account ID. However, creating cross-account access points doesn't grant you access to data in the bucket until you are granted permissions from the bucket owner. The bucket owner must grant the access point owner's account (your account) access to the bucket through the bucket policy. For more information, see Granting permissions for cross-account access points.

Using the S3 console

To create an access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create an access point. The access point must be created in the same Region as the associated bucket.
3. In the left navigation pane, choose **Access Points**.
4. On the **Access Points** page, choose **Create access point**.
5. In the **Access point name** field, enter the name for the access point. For more information about naming access points, see Naming rules for access points.
6. For **Data source**, specify the S3 bucket that you want to use with the access point.

   To use a bucket in your account, choose **Choose a bucket in this account**, and enter or browse for the bucket name.

   To use a bucket in a different AWS account, choose **Specify a bucket in another account**, and enter the AWS account ID and name of the bucket. If you're using a bucket in a different AWS account, the bucket owner must update the bucket policy to authorize requests from the access point. For an example bucket policy, see Granting permissions for cross-account access points.

   > **Note**
   >
   > For information about using an FSx for OpenZFS volume as a data source, see Creating access points with Amazon FSx.

7. Choose a **Network origin**, either **Internet** or **virtual private cloud (VPC)**. If you choose **virtual private cloud (VPC)**, enter the **VPC ID** that you want to use with the access point.

For more information about network origins for access points, see Creating access points restricted to a virtual private cloud.

8. Under **Block Public Access settings for this Access Point**, select the block public access settings that you want to apply to the access point. All block public access settings are enabled by default for new access points. We recommend that you keep all settings enabled unless you know that you have a specific need to disable any of them.

   > **Note**
   >
   > After you create an access point, you can't change its block public access settings.

   For more information about using Amazon S3 Block Public Access with access points, see Managing public access to access points for general purpose buckets.

9. (Optional) Under **Access Point policy - *optional***, specify the access point policy. Before you save your policy, make sure to resolve any security warnings, errors, general warnings, and suggestions. For more information about specifying an access point policy, see Policy examples for access points.

10. Choose **Create access point**.

Using the AWS CLI

The following example command creates an access point named *example-ap* for the bucket *amzn-s3-demo-bucket* in the account *111122223333*. To create the access point, you send a request to Amazon S3 that specifies the following:

- The access point name. For information about naming rules, see the section called "Naming rules for access points".
- The name of the bucket that you want to associate the access point with.
- The account ID for the AWS account that owns the access point.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --
bucket amzn-s3-demo-bucket
```

When you're creating an access point by using a bucket in a different AWS account, include the `--bucket-account-id` parameter. The following example command creates an access point in the AWS account *111122223333*, using the bucket *amzn-s3-demo-bucket2*, which is in the AWS account *444455556666*.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --
bucket amzn-s3-demo-bucket --bucket-account-id 444455556666
```

Using the REST API

You can use the REST API to create an access point. For more information, see CreateAccessPoint in the *Amazon Simple Storage Service API Reference*.

Creating access points with Amazon FSx

You can create and attach an access point to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data. Your data continues to reside on the Amazon FSx file system and continues to be directly accessible for your existing workloads. You continue to manage your storage using all the FSx for OpenZFS storage management capabilities, including backups, snapshots, user and group quotas, and compression.

For instructions on creating an access point and attaching it to an FSx for OpenZFS volume see, Creating an access point in the *FSx for OpenZFS User Guide*.

Creating access points with AWS Backup

AWS Backup creates and attaches access points to S3 recovery points, providing read-only access to S3 backup data using S3 APIs. These access points are created through the AWS Backup console or the `CreateBackupAccessPoint` API, not through S3 access point APIs.

For instructions on creating a backup access point, see Backup access points in the *AWS Backup Developer Guide*.

Creating access points restricted to a virtual private cloud

When you create an access point you can choose to make the access point accessible from the internet, or you can specify that all requests made through that access point must originate from a specific virtual private cloud (VPC). An access point that's accessible from the internet is said to

have a network origin of `Internet`. It can be used from anywhere on the internet, subject to any other access restrictions in place for the access point, underlying data source, and related resources, such as the requested objects. An access point that's only accessible from a specified VPC has a network origin of VPC, and Amazon S3 rejects any request made to the access point that doesn't originate from that VPC.

> **Important**
>
> You can only specify an access point's network origin when you create the access point. After you create the access point, you can't change its network origin.

To restrict an access point to VPC-only access, you include the `VpcConfiguration` parameter with the request to create the access point. In the `VpcConfiguration` parameter, you specify the VPC ID that you want to be able to use the access point. If a request is made through the access point, the request must originate from the VPC or Amazon S3 will reject it.

You can retrieve an access point's network origin using the AWS CLI, AWS SDKs, or REST APIs. If an access point has a VPC configuration specified, its network origin is VPC. Otherwise, the access point's network origin is `Internet`.

Example: Create and restrict an access point to a VPC ID

The following example creates an access point named `example-vpc-ap` for bucket *amzn-s3-demo-bucket* in account 123456789012 that allows access only from the `vpc-1a2b3c` VPC. The example then verifies that the new access point has a network origin of VPC.

AWS CLI

```
aws s3control create-access-point --name example-vpc-ap --account-id 123456789012 --
bucket amzn-s3-demo-bucket --vpc-configuration VpcId=vpc-1a2b3c
```

```
aws s3control get-access-point --name example-vpc-ap --account-id 123456789012

{
    "Name": "example-vpc-ap",
    "Bucket": "amzn-s3-demo-bucket",
    "NetworkOrigin": "VPC",
    "VpcConfiguration": {
        "VpcId": "vpc-1a2b3c"
```

```
    },
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": true,
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2019-11-27T00:00:00Z"
}
```

To use an access point with a VPC, you must modify the access policy for your VPC endpoint. VPC endpoints allow traffic to flow from your VPC to Amazon S3. They have access control policies that control how resources within the VPC are allowed to interact with Amazon S3. Requests from your VPC to Amazon S3 only succeed through an access point if the VPC endpoint policy grants access to both the access point and the underlying bucket.

> **Note**
>
> To make resources accessible only within a VPC, make sure to create a private hosted zone for your VPC endpoint. To use a private hosted zone, modify your VPC settings so that the VPC network attributes `enableDnsHostnames` and `enableDnsSupport` are set to `true`.

For more information about VPC endpoint policies, see Using endpoint policies for Amazon S3 in the *VPC User Guide*.

For a tutorial on creating access points with VPC endpoints, see Managing Amazon S3 access with VPC endpoints and access points.

Example: Create and restrict an access point attached to an FSx for OpenZFS volume to a VPC ID

You can create an access point that is attached it to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data from a specified VPC.

For instructions on creating and restricting an access point attached to an FSx for OpenZFS volume see, the Creating access points restricted to a virtual private cloud (VPC) in the *FSx for OpenZFS User Guide*.

Example: Create and restrict an access point attached to an FSX for ONTAP volume to a VPC ID

You can create an access point that is attached it to an FSx for ONTAP volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data from a specified VPC.

For instructions on creating and restricting an access point attached to an FSx for ONTAP volume see, the *FSx for ONTAP User Guide*.

Managing public access to access points for general purpose buckets

Amazon S3 access points support independent *block public access* settings for each access point. When you create an access point, you can specify block public access settings that apply to that access point. For any request made through an access point, Amazon S3 evaluates the block public access settings for that access point, the underlying bucket, and the bucket owner's account. If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request.

For more information about the S3 Block Public Access feature, see Blocking public access to your Amazon S3 storage.

Important

- All block public access settings are enabled by default for access points. You must explicitly disable any settings that you don't want during access point creation.
- You can not turn off any block public access settings when creating or using an access point attached to an Amazon FSx file system.
- After you create an access point, you can't change its block public access settings.

Example

Example: Create an access point with Custom Block Public Access Settings

This example creates an access point named `example-ap` for bucket *`amzn-s3-demo-bucket`* in account `123456789012` with non-default Block Public Access settings. The example then retrieves the new access point's configuration to verify its Block Public Access settings.

AWS CLI

```
aws s3control create-access-point --name example-ap --account-id
 123456789012 --bucket amzn-s3-demo-bucket--public-access-block-configuration
 BlockPublicAcls=false,IgnorePublicAcls=false,BlockPublicPolicy=true,RestrictPublicBuckets=t
```

```
aws s3control get-access-point --name example-ap --account-id 123456789012

{
    "Name": "example-ap",
    "Bucket": "amzn-s3-demo-bucket",
    "NetworkOrigin": "Internet",
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": false,
        "IgnorePublicAcls": false,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2019-11-27T00:00:00Z"
}
```

Managing your Amazon S3 access points for general purpose buckets

This section explains how to manage your Amazon S3 access points for general purpose buckets using the AWS Management Console, AWS Command Line Interface, or REST API. For information on managing access points attached to an FSx for OpenZFS volume, see Managing your Amazon S3 access points in the *FSx for OpenZFS User Guide*.

> **Note**
>
> You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as deleting buckets or creating S3 Replication configurations. For a complete list of S3 operations that support access points, see Access point compatibility.

Topics

- List your access points for general purpose buckets

- View details for your access point for general purpose buckets
- Delete your access point for a general purpose bucket

List your access points for general purpose buckets

This section explains how to list your access points for general purpose buckets using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To list access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.

Using the AWS CLI

The following `list-access-points` example command shows how you can use the AWS CLI to list your access points.

The following command lists access points for AWS account *111122223333*.

```
aws s3control list-access-points --account-id 111122223333
```

The following command lists access points for AWS account *111122223333* that are attached to bucket *amzn-s3-demo-bucket*.

```
aws s3control list-access-points --account-id 111122223333 --bucket amzn-s3-demo-bucket
```

For more information and examples, see list-access-points in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to list your access points. For more information, see ListAccessPoints in the *Amazon Simple Storage Service API Reference*.

View details for your access point for general purpose buckets

This section explains how to view details for your access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To view details for your access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Select the **Properties** tab to view the access point data source, account ID, AWS Region, creation date, network origin, S3 URI, ARN, and access point alias for the selected access point.
7. Select the **Permissions** tab to view the block public access settings and access point policy for the selected access point.

> **Note**
>
> You can't change any block public access settings for an access point after the access point is created.

Using the AWS CLI

The following `get-access-point` example command shows how you can use the AWS CLI to view details for your access point.

The following command lists details for the access point *my-access-point* for AWS account *111122223333* attached to S3 bucket *amzn-s3-demo-bucket*.

```
aws s3control get-access-point --name my-access-point --account-id 111122223333
```

Example output:

```
{
    "Name": "my-access-point",
    "Bucket": "amzn-s3-demo-bucket",
    "NetworkOrigin": "Internet",
    "PublicAccessBlockConfiguration": {
        "BlockPublicAcls": true,
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2016-08-29T22:57:52Z",
    "Alias": "my-access-point-u1ny6bhm7moymqx8cuon8o1g4mwikuse2a-s3alias",
    "AccessPointArn": "arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point",
    "Endpoints": {
        "ipv4": "s3-accesspoint.AWS Region.amazonaws.com",
        "fips": "s3-accesspoint-fips.AWS Region.amazonaws.com",
        "fips_dualstack": "s3-accesspoint-fips.dualstack.AWS Region.amazonaws.com",
        "dualstack": "s3-accesspoint.dualstack.AWS Region.amazonaws.com"
    },
    "BucketAccountId": "111122223333"
}
```

The following command lists details for the access point *example-fsx-ap* for AWS account *444455556666*. This access point is attached to an Amazon FSx file system.

```
aws s3control get-access-point --name example-fsx-ap --account-id 444455556666
```

Example output:

```
{
    "Name": "example-fsx-ap",
    "Bucket": "",
    "NetworkOrigin": "Internet",
    "PublicAccessBlockConfiguration": {
```

```
        "BlockPublicAcls": true,
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2025-01-19T14:16:12Z",
    "Alias": "example-fsx-ap-qrqbyebjtsxorhhaa5exx6r3q7-ext-s3alias",
    "AccessPointArn": "arn:aws:s3:AWS Region:444455556666:accesspoint/example-fsx-ap",
    "Endpoints": {
        "ipv4": "s3-accesspoint.AWS Region.amazonaws.com",
        "fips": "s3-accesspoint-fips.AWS Region.amazonaws.com",
        "fips_dualstack": "s3-accesspoint-fips.dualstack.AWS Region.amazonaws.com",
        "dualstack": "s3-accesspoint.dualstack.AWS Region.amazonaws.com"
    },
    "DataSourceId": "arn:aws::fsx:AWS Region:444455556666:file-system/
fs-5432106789abcdef0/volume/vol-0123456789abcdef0",
    "DataSourceType": "FSX_OPENZFS"
}
```

For more information and examples, see get-access-point in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see GetAccessPoint in the *Amazon Simple Storage Service API Reference*.

Delete your access point for a general purpose bucket

This section explains how to delete your access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To delete for your access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.

5. Choose the name of the access point you want to manage or use.
6. From the **Access Point** page, select **Delete** to delete the access point you've selected.
7. To confirm deletion, type the name of the access point and choose **Delete**.

Using the AWS CLI

The following `delete-access-point` example command shows how you can use the AWS CLI to delete your access point.

The following command deletes the access point *`my-access-point`* for AWS account *`111122223333`*.

```
aws s3control delete-access-point --name my-access-point --account-id 111122223333
```

For more information and examples, see delete-access-point in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see DeleteAccessPoint in the *Amazon Simple Storage Service API Reference*.

Using Amazon S3 access points for general purpose buckets

The following examples demonstrate how to use access points for general purpose buckets with compatible operations in Amazon S3.

> **Note**
>
> S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

You can only use access points for general purpose buckets to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see Access point compatibility.

Topics

- List objects through an access point for a general purpose bucket
- Download an object through an access point for a general purpose bucket
- Configure access control lists (ACLs) through an access point for a general purpose bucket
- Upload an object through an access point for a general purpose bucket
- Add a tag-set through an access point for a general purpose bucket
- Delete an object through an access point for a general purpose bucket

List objects through an access point for a general purpose bucket

This section explains how to list your objects through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To list your objects through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, you can view the name of objects that you want to access through the access point. While you're using the access point, you can only perform the object operations that are allowed by the access point permissions.

> **Note**
>
> - The console view always shows all objects in the bucket. Using an access point as described in this procedure restricts the operations you can perform on those objects, but not whether you can see that they exist in the bucket.

- The AWS Management Console doesn't support using virtual private cloud (VPC) access points to access bucket resources. To access bucket resources from a VPC access point, use the AWS CLI, AWS SDKs, or Amazon S3 REST APIs.

Using the AWS CLI

The following `list-objects-v2` example command shows how you can use the AWS CLI to list your object through an access point.

The following command lists objects for AWS account *111122223333* using access point *my-access-point*.

```
aws s3api list-objects-v2 --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point
```

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

For more information and examples, see list-access-points in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to list your access points. For more information, see ListObjectsV2 in the *Amazon Simple Storage Service API Reference*.

Download an object through an access point for a general purpose bucket

This section explains how to download an object through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To download an object through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of object that you want to download.
7. Choose **Download**.

Using the AWS CLI

The following `get-object` example command shows how you can use the AWS CLI to download an object through an access point.

The following command downloads the object `puppy.jpg` for AWS account *111122223333* using access point *my-access-point*. You must include an `outfile`, which is a file name for the downloaded object, such as *my_downloaded_image.jpg*.

```
aws s3api get-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg my_downloaded_image.jpg
```

> **Note**
>
> S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

For more information and examples, see get-object in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to download an object through an access point. For more information, see GetObject in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

You can use the AWS SDK for Python to download an object through an access point.

Python

In the following example, the file named *hello.txt* is downloaded for AWS account *111122223333* using the access point named *my-access-point*.

```
import boto3
s3 = boto3.client('s3')
s3.download_file('arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point',
 'hello.txt', '/tmp/hello.txt')
```

Configure access control lists (ACLs) through an access point for a general purpose bucket

This section explains how to configure ACLs through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API. For more information about ACLs, see Access control list (ACL) overview.

Using the S3 console

To configure ACLs through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object you wish to configure an ACL for.
7. Under the **Permissions** tab, select **Edit** to configure the object ACL.

> **Note**
>
> Amazon S3 currently doesn't support changing an access point's block public access settings after the access point has been created.

Using the AWS CLI

The following `put-object-acl` example command shows how you can use the AWS CLI to configure access permissions through an access point using an ACL.

The following command applies an ACL to an existing object `puppy.jpg` through an access point owned by AWS account *111122223333*.

```
aws s3api put-object-acl --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --acl private
```

> **Note**
>
> S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

For more information and examples, see put-object-acl in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to configure access permissions through an access point using an ACL. For more information, see PutObjectAcl in the *Amazon Simple Storage Service API Reference*.

Upload an object through an access point for a general purpose bucket

This section explains how to upload an object through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To upload an object through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.

4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select **Upload**.
7. Drag and drop files and folders you want to upload here, or choose **Add files** or **Add folder**.

   > **Note**
   >
   > The maximum size of a file that you can upload by using the Amazon S3 console is 160 GB. To upload a file larger than 160 GB, use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

8. To change access control list permissions, choose **Permissions**.
9. Under **Access control list (ACL)**, edit the permissions.

   For information about object access permissions, see Using the S3 console to set ACL permissions for an object. You can grant read access to your objects to the public (everyone in the world) for all of the files that you're uploading. However, we recommend not changing the default setting for public read access. Granting public read access is applicable to a small subset of use cases, such as when buckets are used for websites. You can always change the object permissions after you upload the object.
10. To configure other additional properties, choose **Properties**.
11. Under **Storage class**, choose the storage class for the files that you're uploading.

    For more information about storage classes, see Understanding and managing Amazon S3 storage classes.
12. To update the encryption settings for your objects, under **Server-side encryption settings**, do the following.

    a. Choose **Specify an encryption key**.

    b. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.

    c. If you chose **Override bucket settings for default encryption**, you must configure the following encryption settings.

- To encrypt the uploaded files by using keys that are managed by Amazon S3, choose **Amazon S3 managed key (SSE-S3)**.

  For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

- To encrypt the uploaded files by using keys stored in AWS Key Management Service (AWS KMS), choose **AWS Key Management Service key (SSE-KMS)**. Then choose one of the following options for **AWS KMS key**:

  - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

    Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

  - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.

  - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

    For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

    Important

    You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.
    Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

13. To use additional checksums, choose **On**. Then for **Checksum function**, choose the function that you would like to use. Amazon S3 calculates and stores the checksum value after it

receives the entire object. You can use the **Precalculated value** box to supply a precalculated value. If you do, Amazon S3 compares the value that you provided to the value that it calculates. If the two values do not match, Amazon S3 generates an error.

Additional checksums enable you to specify the checksum algorithm that you would like to use to verify your data. For more information about additional checksums, see Checking object integrity in Amazon S3.

14. To add tags to all of the objects that you are uploading, choose **Add tag**. Enter a tag name in the **Key** field. Enter a value for the tag.

    Object tagging gives you a way to categorize storage. Each tag is a key-value pair. Key and tag values are case sensitive. You can have up to 10 tags per object. A tag key can be up to 128 Unicode characters in length, and tag values can be up to 255 Unicode characters in length. For more information about object tags, see Tagging your objects.

15. To add metadata, choose **Add metadata**.

    a. Under **Type**, choose **System defined** or **User defined**.

       For system-defined metadata, you can select common HTTP headers, such as **Content-Type** and **Content-Disposition**. For a list of system-defined metadata and information about whether you can add the value, see System-defined object metadata. Any metadata starting with the prefix `x-amz-meta-` is treated as user-defined metadata. User-defined metadata is stored with the object and is returned when you download the object. Both the keys and their values must conform to US-ASCII standards. User-defined metadata can be as large as 2 KB. For more information about system-defined and user-defined metadata, see Working with object metadata.

    b. For **Key**, choose a key.

    c. Type a value for the key.

16. To upload your objects, choose **Upload**.

    Amazon S3 uploads your object. When the upload completes, you can see a success message on the **Upload: status** page.

Using the AWS CLI

The following `put-object` example command shows how you can use the AWS CLI to upload an object through an access point.

The following command uploads the object `puppy.jpg` for AWS account *111122223333* using access point *my-access-point*.

```
aws s3api put-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --body puppy.jpg
```

> **Note**
>
> S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

For more information and examples, see put-object in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to upload an object through an access point. For more information, see PutObject in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

You can use the AWS SDK for Python to upload an object through an access point.

Python

In the following example, the file named *hello.txt* is uploaded for AWS account *111122223333* using the access point named *my-access-point*.

```
import boto3
s3 = boto3.client('s3')
s3.upload_file('/tmp/hello.txt', 'arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point', 'hello.txt')
```

Add a tag-set through an access point for a general purpose bucket

This section explains how to add a tag-set through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API. For more information, see Tagging your objects.

Using the S3 console

To add a tag-set through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object you wish to add a tag-set to.
7. Under the **Properties** tab, find the **Tags** sub-header and choose **Edit**.
8. Review the objects listed, and choose **Add tag**.
9. Each object tag is a key-value pair. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**.

   You can enter up to 10 tags for an object.
10. Choose **Save changes**.

Using the AWS CLI

The following `put-object-tagging` example command shows how you can use the AWS CLI to add a tag-set through an access point.

The following command adds a tag-set for existing object `puppy.jpg` using access point *`my-access-point`*.

```
aws s3api put-object-tagging --bucket arn:aws:s3:AWS
 Region:111122223333:accesspoint/my-access-point --key puppy.jpg --tagging
 TagSet=[{Key="animal",Value="true"}]
```

> **Note**
>
> S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

For more information and examples, see put-object-tagging in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to add a tag-set to an object through an access point. For more information, see PutObjectTagging in the *Amazon Simple Storage Service API Reference*.

Delete an object through an access point for a general purpose bucket

This section explains how to delete an object through an access point for a general purpose bucket using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To delete an object or objects through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object or objects you wish to delete.
7. Review the objects listed for deletion, and type *delete* in the confirmation box.
8. Choose **Delete objects**.

Using the AWS CLI

The following `delete-object` example command shows how you can use the AWS CLI to delete an object through an access point.

The following command deletes the existing object `puppy.jpg` using access point *`my-access-point`*.

```
aws s3api delete-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg
```

> **Note**
>
> S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see Access point aliases.

For more information and examples, see delete-object in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to delete an object through an access point. For more information, see DeleteObject in the *Amazon Simple Storage Service API Reference*.

Using tags with S3 Access Points for general purpose buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 Access Points. You can tag access points when you create them or manage tags on existing access points. For general information about tags, see Tagging for cost allocation or attribute-based access control (ABAC).

> **Note**
>
> There is no additional charge for using tags on access points beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

Common ways to use tags with access points

Attribute-based access control (ABAC) allows you to scale access permissions and grant access to access points based on their tags. For more information about ABAC in Amazon S3, see Using tags for ABAC.

ABAC for S3 Access Points

Amazon S3 Access Points support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and Access Points policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to access points based on the access points's tags by using the following global condition keys:

- `aws:ResourceTag/key-name`

  > **Important**
  >
  > The `aws:ResourceTag` condition key can only be used for S3 actions performed via an access point ARN for general purpose buckets and covers the underlying access point tags only.

  - Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `Dept` with the value `Marketing`. For more information, see Controlling access to AWS resources.
- `aws:RequestTag/key-name`
  - Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `Dept` and that it has the value `Accounting`. For more information, see Controlling access during AWS requests. You can use this condition key to restrict which tag key-value pairs can be passed during the `TagResource` and `CreateAccessPoint` API operations.
- `aws:TagKeys`
  - Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information,

see Controlling access based on tag keys. You can create an access point with tags. To allow tagging during the `CreateAccessPoint` API operation, you must create a policy that includes both the `s3:TagResource` and `s3:CreateAccessPoint` actions. You can then use the `aws:TagKeys` condition key to enforce using specific tags in the `CreateAccessPoint` request.

- `s3:AccessPointTag/tag-key`
  - Use this condition key to grant permissions to specific data via access points using tags. When using `aws:ResourceTag/tag-key` in an IAM policy, both the access point as well as the bucket to which the access point points to are required to have the same tag as they are both considered during authorization. If you want to control access to your data specifically via the access-point tag only, you can use `s3:AccessPointTag/tag-key` condition key.

Example ABAC policies for access points

See the following example ABAC policies for Amazon S3 Access Points.

1.1 - IAM policy to create or modify buckets with specific tags

In this IAM policy, users or roles with this policy can only create access points if they tag the access points with the tag key `project` and tag value `Trinity` in the access points creation request. They can also add or modify tags on existing access points as long as the `TagResource` request includes the tag key-value pair `project:Trinity`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateAccessPointWithTags",
      "Effect": "Allow",
      "Action": [
        "s3:CreateAccessPoint",
        "s3:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": [
            "Trinity"
          ]
        }
```

```
      }
    }
  ]
}
```

1.2 - IAM policy to modify tags on existing resources maintaining tagging governence

In this IAM policy, IAM principals (users or roles) can modify tags on an access point only if the value of the access point's `project` tag matches the value of the principal's `project` tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these access points. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your access points.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceTaggingRulesOnModification",
      "Effect": "Allow",
      "Action": [
        "s3:TagResource"
      ],
      "Resource": "arn:aws::s3:region:111122223333:accesspoint/my-access-point",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "project",
            "environment",
            "owner",
            "cost-center"
          ]
        }
      }
    }
  ]
}
```

1.3 - Using the s3:AccessPointTag condition key

In this IAM policy, the condition statement allows access to the bucket's data if the access point has the tag key `Environment` and tag value `Production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToSpecificAccessPoint",
      "Effect": "Allow",
      "Action": "*",
      "Resource": "arn:aws::s3:region:111122223333:accesspoint/my-access-point",
      "Condition": {
        "StringEquals": {
          "s3:AccessPointTag/Environment": "Production"
        }
      }
    }
  ]
}
```

1.4 - Using a bucket delegate policy

In Amazon S3, you can delegate access to or control of your S3 bucket policy to another AWS account or to a specific AWS Identity and Access Management (IAM) user or role in the other account. The delegate bucket policy grants this other account, user, or role permission to your bucket and its objects. For more information, see Permission delegation.

If you use a delegate bucket policy, you can use an IAM policy like the following. The condition statement allows access to the bucket\'s data if the access point has the tag key `Environment` and tag value `Production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToSpecificAccessPoint",
      "Effect": "Allow",
      "Action": "*",
      "Resource": "arn:aws::s3:region:111122223333:accesspoint/my-access-point",
      "Condition": {
```

```
        "StringEquals": {
          "s3:AccessPointTag/Environment": "Production"
        }
      }
    }
  ]
}
```

Working with tags for access points for general purpose buckets

You can add or manage tags for access points using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: TagResource, UntagResource, and ListTagsForResource. For more information, see:

Topics

- Creating access points with tags
- Adding a tag to an access point
- Viewing access point tags
- Deleting a tag from an access point

Creating access points with tags

You can tag access points when you create them. There is no additional charge for using tags on access points beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging access points, see Using tags with S3 Access Points for general purpose buckets.

Permissions

To create an access point with tags, you must have the following permissions:

- `s3:CreateBucket`
- `s3:TagResource`

Troubleshooting errors

If you encounter an error when attempting to create an access point with tags, you can do the following:

- Verify that you have the required Permissions to create the access point and add a tag to it.
- Check your IAM user policy for any attribute-based access control (ABAC) conditions. You may be required to label your access points only with specific tag keys and values. For more information, see Using tags for attribute-based access control (ABAC).

Steps

You can create an access point with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create an access point with tags using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose **create access point** to create a new access point.
4. On the **Create access point** page, **Tags** is an option when creating a new access point.
5. Enter a name for the access point. For more information, see Access points naming rules, restrictions, and limitations.
6. Choose **Add new Tag** to open the **Tags** editor and enter a tag key-value pair. The tag key is required, but the value is optional.
7. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
8. After you complete specifying the options for your new access point, choose **Create access point**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to create an access point with tags by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
CreateAccessPointRequest createAccessPointRequest =
 CreateAccessPointRequest.builder()
                .accountId(111122223333)
```

```
                .name(my-access-point)
                .bucket(amzn-s3-demo-bucket)

.tags(Collections.singletonList(Tag.builder().key("key1").value("value1").build()))
                .build();
awss3Control.createAccessPoint(createAccessPointRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for creating an access point with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- CreateAccessPoint

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create an access point with tags by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control create-access-point --name my-access-point \
--bucket amzn-s3-demo-bucket \
--account-id 111122223333 \ --profile personal \
--tags [{Key=key1,Value=value1},{Key=key2,Value=value2}] \
--region region
```

Adding a tag to an access point

You can add tags to Amazon S3 Access Points and modify these tags. There is no additional charge for using tags on access points beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging access points, see Using tags with S3 Access Points for general purpose buckets.

Permissions

To add a tag to an access point, you must have the following permission:

- `s3:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to an access point, you can do the following:

- Verify that you have the required Permissions to add a tag to an access point.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to access points by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To add tags to an access point using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.
7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

> This example shows you how to add tags to an access point by using the AWS SDK for Java 2.x. To use the command replace the *`user input placeholders`* with your own information.

```
TagResourceRequest tagResourceRequest =
 TagResourceRequest.builder().resourceArn(arn:aws::s3:region:111122223333:accesspoint/
my-access-point/*)
.accountId(111122223333)
.tags(List.of(Tag.builder().key("key1").value("value1").build(),
Tag.builder().key("key2").value("value2").build()))
.build();
awss3Control.tagResource(tagResourceRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for adding tags to an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- TagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to an access point by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request:

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:111122223333:accesspoint/my-access-point/* \
--tags "Key=key1,Value=value1"
```

Response:

```
{
  "ResponseMetadata": {
      "RequestId": "EXAMPLE123456789",
      "HTTPStatusCode": 200,
      "HTTPHeaders": {
          "date": "Wed, 19 Jun 2025 10:30:00 GMT",
          "content-length": "0"
      },
```

```
      "RetryAttempts": 0
  }
}
```

Viewing access point tags

You can view or list tags applied to access points. For more information about tags, see Using tags with S3 Access Points for general purpose buckets.

Permissions

To view tags applied to an access point, you must have the following permission:

- `s3:ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of an access point, you can do the following:

- Verify that you have the required Permissions to view or list the tags of the access point.

Steps

You can view tags applied to access points by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to an access point using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the access point.
6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your access point by AWS services.

Using the AWS SDKs

This section provides an example of how to view tags applied to an access point by using the AWS SDKs.

SDK for Java 2.x

This example shows you how to view tags applied to an access point by using the AWS SDK for Java 2.x.

```
ListTagsForResourceRequest listTagsForResourceRequest = ListTagsForResourceRequest
.builder().resourceArn(arn:aws::s3:region:111122223333:accesspoint/my-access-point/
*)
                .accountId(111122223333).build();
awss3Control.listTagsForResource(listTagsForResourceRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- ListTagsforResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to an access point. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:444455556666:bucket/prefix--use1-az4--x-s3 \
```

Response - tags present:

```
{
```

```
  "Tags": [
      {
          "Key": "MyKey1",
          "Value": "MyValue1"
      },
      {
          "Key": "MyKey2",
          "Value": "MyValue2"
      },
      {
          "Key": "MyKey3",
          "Value": "MyValue3"
      }
  ]
}
```

Response - no tags present:

```
{
  "Tags": []
}
```

Deleting a tag from an access point

You can remove tags from Amazon S3 Access Points. An AWS tag is a key-value pair that holds metadata about resources, in this case Access Points. For more information about tags, see Using tags with S3 Access Points for general purpose buckets.

> **Note**
>
> If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the access point.

Permissions

To delete a tag from an access point, you must have the following permission:

- `s3:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from an access point, you can do the following:

- Verify that you have the required Permissions to delete a tag from an access point.

Steps

You can delete tags from access points by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from an access point using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Points (General Purpose Buckets)**.
3. Choose the access point name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to delete tags from an access point by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
UntagResourceRequest tagResourceRequest = UntagResourceRequest.builder()
                .resourceArn(arn:aws::s3:region:111122223333:accesspoint/my-access-
point/*)
```

```
                .accountId(111122223333)
                .tagKeys(List.of("key1", "key2")).build();
awss3Control.untagResource(tagResourceRequest);
```

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from an access point, see the following section in the *Amazon Simple Storage Service API Reference*:

- UnTagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from an access point by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws s3control untag-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:444455556666:access-point/my-access-point \
--tag-keys "tagkey1" "tagkey2"

  aws s3control untag-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:region:444455556666:accesspointmy-access-point/* \
--tag-keys "key1" "key2"
```

Response:

```
{
  "ResponseMetadata": {
    "RequestId": "EXAMPLE123456789",
    "HTTPStatusCode": 204,
    "HTTPHeaders": {
        "date": "Wed, 19 Jun 2025 10:30:00 GMT",
        "content-length": "0"
    },
```

```
    "RetryAttempts": 0
  }
}
```

Managing access with S3 Access Grants

To adhere to the principle of least privilege, you define granular access to your Amazon S3 data based on applications, personas, groups, or organizational units. You can use various approaches to achieve granular access to your data in Amazon S3, depending on the scale and complexity of the access patterns.

The simplest approach for managing access to small-to-medium numbers of datasets in Amazon S3 by AWS Identity and Access Management (IAM) principals is to define IAM permission policies and S3 bucket policies. This strategy works, so long as the necessary policies fit within the policy size limits of S3 bucket policies (20 KB) and IAM policies (5 KB), and within the number of IAM principals allowed per account.

As your number of datasets and use cases scales, you might require more policy space. An approach that offers significantly more space for policy statements is to use S3 Access Points as additional endpoints for S3 buckets, because each access point can have its own policy. You can define quite granular access control patterns, because you can have thousands of access points per AWS Region per account, with a policy up to 20 KB in size for each access point. Although S3 Access Points increases the amount of policy space available, it requires a mechanism for clients to discover the right access point for the right dataset.

A third approach is to implement an IAM session broker pattern, in which you implement access-decision logic and dynamically generate short-term IAM session credentials for each access session. While the IAM session broker approach supports arbitrarily dynamic permissions patterns and scales effectively, you must build the access-pattern logic.

Instead of using these approaches, you can use S3 Access Grants to manage access to your Amazon S3 data. S3 Access Grants provides a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. In addition, you can use S3 Access Grants to grant access to both IAM principals and directly to users or groups from your corporate directory.

You commonly define permissions to data in Amazon S3 by mapping users and groups to datasets. You can use S3 Access Grants to define direct access mappings of S3 prefixes to users and roles within Amazon S3 buckets and objects. With the simplified access scheme in S3 Access Grants, you

can grant read-only, write-only, or read-write access on a per-S3-prefix basis to both IAM principals and directly to users or groups from a corporate directory. With these S3 Access Grants capabilities, applications can request data from Amazon S3 on behalf of the application's current authenticated user.

When you integrate S3 Access Grants with the trusted identity propagation feature of AWS IAM Identity Center, your applications can make requests to AWS services (including S3 Access Grants) directly on behalf of an authenticated corporate directory user. Your applications no longer need to first map the user to an IAM principal. Furthermore, because end-user identities are propagated all the way to Amazon S3, auditing which user accessed which S3 object is simplified. You no longer need to reconstruct the relationship between different users and IAM sessions. When you're using S3 Access Grants with IAM Identity Center trusted identity propagation, each AWS CloudTrail data event for Amazon S3 contains a direct reference to the end user on whose behalf the data was accessed.

Trusted identity propagation is an AWS IAM Identity Center feature that administrators of connected AWS services can use to grant and audit access to service data. Access to this data is based on user attributes such as group associations. Setting up trusted identity propagation requires collaboration between the administrators of connected AWS services and the IAM Identity Center administrators. For more information, see Prerequisites and considerations.

For more information about S3 Access Grants, see the following topics.

S3 Access Grants concepts

S3 Access Grants workflow

The S3 Access Grants workflow is:

1. Create an S3 Access Grants instance. See Working with S3 Access Grants instances.
2. Within your S3 Access Grants instance, register locations in your Amazon S3 data, and map these locations to AWS Identity and Access Management (IAM) roles. See Register a location.
3. Create grants for grantees, which give grantees access to your S3 resources. See Working with grants in S3 Access Grants.
4. The grantee requests temporary credentials from S3 Access Grants. See Request access to Amazon S3 data through S3 Access Grants.
5. The grantee accesses the S3 data using those temporary credentials. See Accessing S3 data using credentials vended by S3 Access Grants.

For more information, see Getting started with S3 Access Grants.

S3 Access Grants instances

An *S3 Access Grants instance* is a logical container for individual *grants*. When you create an S3 Access Grants instance, you must specify an AWS Region. Each AWS Region in your AWS account can have one S3 Access Grants instance. For more information, see Working with S3 Access Grants instances.

If you want to use S3 Access Grants to grant access to user and group identities from your corporate directory, you must also associate your S3 Access Grants instance with an AWS IAM Identity Center instance. For more information, see S3 Access Grants and corporate directory identities.

A newly created S3 Access Grants instance is empty. You must register a location in the instance, which can be the S3 default path (`s3://`), a bucket, or a prefix within a bucket. After you register at least one location, you can create access grants that give access to data in this registered location.

Locations

An S3 Access Grants *location* maps buckets or prefixes to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials

to the grantee that's accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in the AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the *amzn-s3-demo-bucket* is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

- The default S3 location (`s3://`)
- A bucket (for example, *amzn-s3-demo-bucket*) or multiple buckets
- A bucket and a prefix (for example, *amzn-s3-demo-bucket*`/prefix*`) or multiple prefixes

For the maximum number of locations that you can register in your S3 Access Grants instance, see S3 Access Grants limitations. For more information about registering an S3 Access Grants location, see Register a location.

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. So, no access has been granted yet to any of your S3 data. You can now create access grants to give access. For more information about creating grants, see Working with grants in S3 Access Grants.

Grants

An individual *grant* in an S3 Access Grants instance allows a specific identity—an IAM principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance.

When you create a grant, you don't have to grant access to the entire registered location. You can narrow the grant's scope of access within a location. If the registered location is the default S3 path (`s3://`), you are required to narrow the scope of the grant to a bucket, a prefix within a bucket, or a specific object. If the registered location of the grant is a bucket or a prefix, then you can give access to the entire bucket or prefix, or you can optionally narrow the scope of the grant to a prefix, subprefix, or an object.

In the grant, you also set the access level of the grant to READ, WRITE, or READWRITE. Suppose you have a grant that gives the corporate directory group `01234567-89ab-cdef-0123-456789abcdef` READ access to the bucket `s3://`*`amzn-s3-demo-bucket`*`/projects/items/*`. Users in this group can have READ access to every object that has an object key name which starts with the prefix `projects/items/` in the bucket named *`amzn-s3-demo-bucket`*.

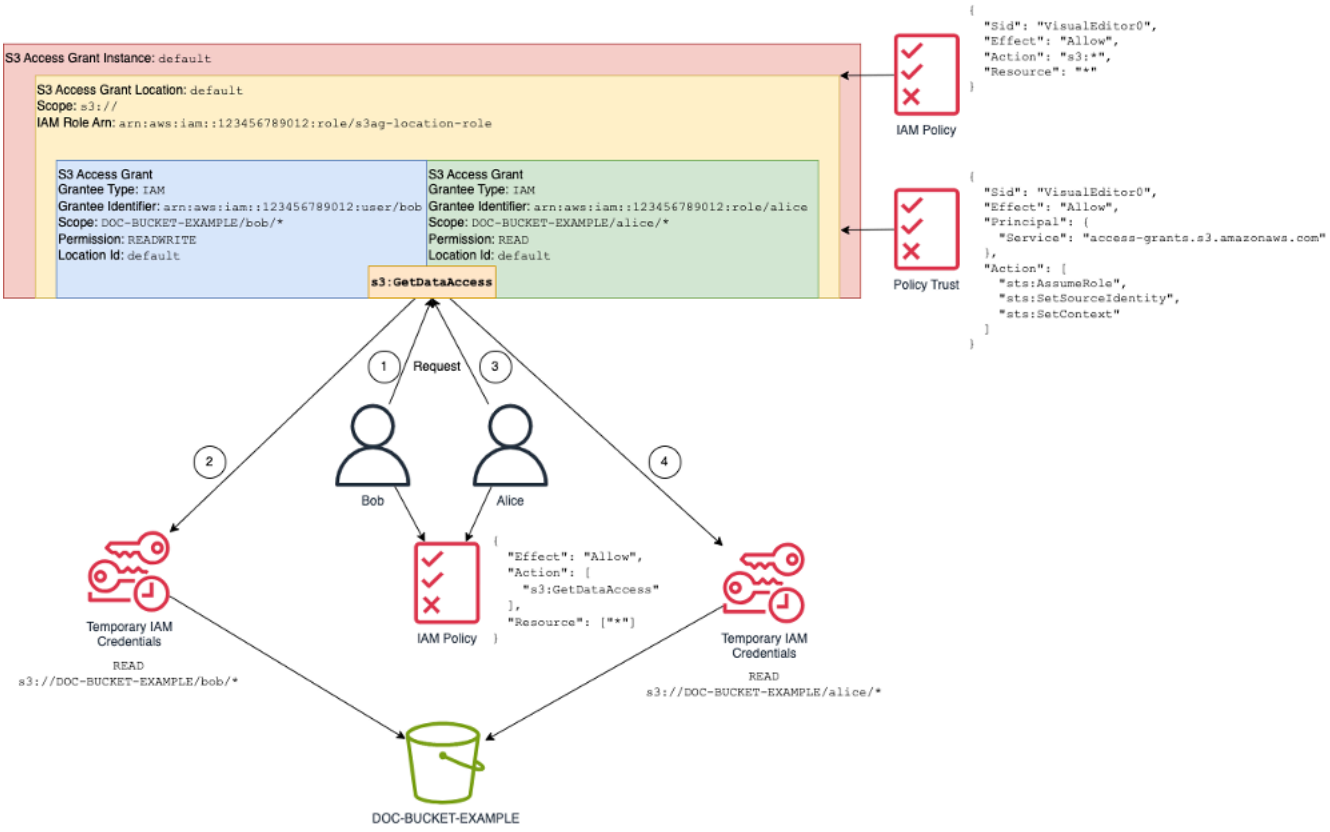
For the maximum number of grants that you can create in your S3 Access Grants instance, see S3 Access Grants limitations. For more information about creating grants, see Create grants.

S3 Access Grants temporary credentials

After you create a grant, an authorized application that utilizes the identity specified in the grant can request *just-in-time access credentials*. To do this, the application calls the GetDataAccess S3 API operation. Grantees can use this API operation to request access to the S3 data you have shared with them.

The S3 Access Grants instance evaluates the `GetDataAccess` request against the grants that it has. If there is a matching grant for the requestor, S3 Access Grants assumes the IAM role that's associated with the registered location of the matching grant. S3 Access Grants scopes the permissions of the temporary credentials to access only the S3 bucket, prefix, or object that's specified by the grant's scope.

The expiration time of the temporary access credentials defaults to 1 hour, but you can set it to any value from 15 minutes to 12 hours. See the maximum duration session in the AssumeRole API reference.



How it works

In the following diagram, a default Amazon S3 location with the scope `s3://` is registered with the IAM role `s3ag-location-role`. This IAM role has permissions to perform Amazon S3 actions within the account when its credentials are obtained through S3 Access Grants.

Within this location, two individual access grants are created for two IAM users. The IAM user Bob is granted both `READ` and `WRITE` access on the `bob/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. Another IAM role, Alice, is granted only `READ` access on the `alice/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in blue, is defined for Bob to access the prefix `bob/` in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in green, is defined for Alice to access the prefix `alice/` in the `DOC-BUCKET-EXAMPLE` bucket.

When it's time for Bob to `READ` data, the IAM role that's associated with the location that his grant is in calls the S3 Access Grants GetDataAccess API operation. If Bob tries to `READ` any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, the `GetDataAccess` request returns a set of temporary IAM session credentials with permission to `s3://DOC-BUCKET-EXAMPLE/bob/*`. Similarly, Bob can `WRITE` to any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, because the grant also allows that.

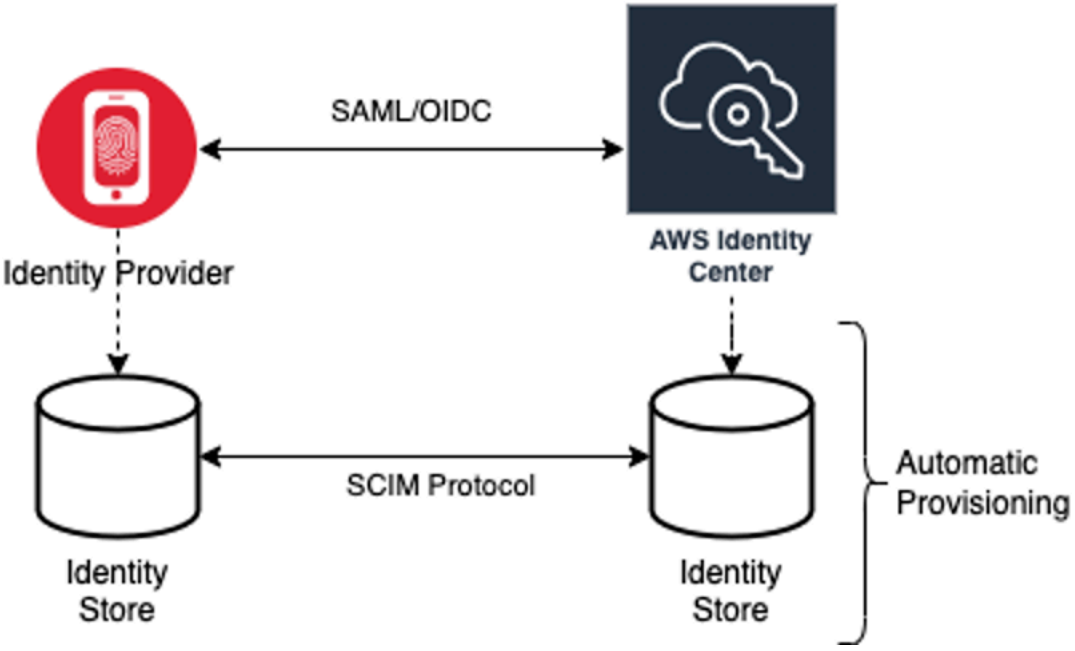
Similarly, Alice can `READ` anything that starts with `s3://DOC-BUCKET-EXAMPLE/alice/`. However, if she tries to `WRITE` anything to any bucket, prefix, or object in `s3://`, she will get an Access Denied (403 Forbidden) error, because there is no grant that gives her `WRITE` access to any data. In addition, if Alice requests any level of access (`READ` or `WRITE`) to data outside of `s3://DOC-BUCKET-EXAMPLE/alice/`, she will again receive an Access Denied error.

This pattern scales to a high number of users and buckets and simplifies management of those permissions. Rather than editing potentially large S3 bucket policies every time you want to add or remove an individual user-prefix access relationship, you can add and remove individual, discrete grants.

S3 Access Grants and corporate directory identities

You can use Amazon S3 Access Grants to grant access to AWS Identity and Access Management (IAM) principals (users or roles), both in the same AWS account and in others. However, in many cases, the entity accessing the data is an end user from your corporate directory. Instead of granting access to IAM principals, you can use S3 Access Grants to grant access directly to your corporate users and groups. With S3 Access Grants, you no longer need to map your corporate identities to intermediate IAM principals in order to access your S3 data through your corporate applications.

This new functionality—support for using end-user identities access to data—is provided by associating your S3 Access Grants instance with an AWS IAM Identity Center instance. IAM Identity Center supports standards-based identity providers and is the hub in AWS for any services or features, including S3 Access Grants, that support end-user identities. IAM Identity Center provides



authentication support for corporate identities through its trusted identity propagation feature. For more information, see Trusted identity propagation across applications.

To get started with workforce identity support in S3 Access Grants, as a prerequisite, you start in IAM Identity Center by configuring identity provisioning between your corporate identity provider and IAM Identity Center. IAM Identity Center supports corporate identity providers such as Okta, Microsoft Entra ID (formerly Azure Active Directory), or any other external identity provider (IdP) that supports the System for Cross-domain Identity Management (SCIM) protocol. When you connect IAM Identity Center to your IdP and enable automatic provisioning, the users and groups from your IdP are synchronized into the identity store in IAM Identity Center. After this step, IAM Identity Center has its own view of your users and groups, so that you can refer to them by using other AWS services and features, such as S3 Access Grants. For more information about configuring IAM Identity Center automatic provisioning, see Automatic provisioning in the *AWS IAM Identity Center User Guide*.

IAM Identity Center is integrated with AWS Organizations so that you can centrally manage permissions across multiple AWS accounts without configuring each of your accounts manually. In a typical organization, your identity administrator configures one IAM Identity Center instance for the entire organization, as a single point of identity synchronization. This IAM Identity Center instance typically runs in a dedicated AWS account in your organization. In this common configuration, you can refer to user and group identities in S3 Access Grants from any AWS account in the organization.

However, if your AWS Organizations administrator hasn't yet configured a central IAM Identity Center instance, you can create a local one in the same account and AWS Region as your S3 Access Grants instance. If you have an IAM Identity Center instance configured in a different AWS Region, you can also replicate this instance to the same AWS Region as your S3 Access Grants instance. Such a configuration is more common for proof-of-concept or local development use cases. In all cases, the IAM Identity Center instance must be in the same AWS Region as the S3 Access Grants instance to which it will be associated.

In the following diagram of an IAM Identity Center configuration with an external IdP, the IdP is configured with SCIM to synchronize the identity store from the IdP to the identity store in IAM Identity Center.

To use your corporate directory identities with S3 Access Grants, do the following:

- Set up Automatic provisioning in IAM Identity Center to synchronize user and group information from your IdP into IAM Identity Center.
- Configure your external identity source within IAM Identity Center as a trusted token issuer. For more information, see Trusted identity propagation across applications in the *AWS IAM Identity Center User Guide*.
- Associate your S3 Access Grants instance with your IAM Identity Center instance. You can do this when you create your S3 Access Grants instance. If you've already created your S3 Access Grants instance, see Associate or disassociate your IAM Identity Center instance.

How directory identities can access S3 data

Suppose that you have corporate directory users who need to access your S3 data through a corporate application, for example, a document-viewer application, that is integrated with your external IdP (for example, Okta) to authenticate users. Authentication of the user in these applications is typically done through redirects in the user's web browser. Because users in the directory are not IAM principals, your application needs IAM credentials with which it can call the S3 Access Grants `GetDataAccess` API operation to get access credentials to S3 data on the users' behalf. Unlike IAM users and roles who get credentials themselves, your application needs a way to represent a directory user, who isn't mapped to an IAM role, so that the user can get data access through S3 Access Grants.

This transition, from authenticated directory user to an IAM caller that can make requests to S3 Access Grants on behalf of the directory user, is done by the application through the trusted token issuer feature of IAM Identity Center. The application, after authenticating the directory user, has an identity token from the IdP (for example, Okta) that represents the directory user according to Okta. The trusted token issuer configuration in IAM Identity Center enables the application to exchange this Okta token (the Okta tenant is configured as the "trusted issuer") for a different identity token from IAM Identity Center that will securely represent the directory user within AWS services. The data application will then assume an IAM role, providing the directory user's token from IAM Identity Center as additional context. The application can use the resulting IAM session to call S3 Access Grants. The token represents both the identity of the application (the IAM principal itself) as well as the directory user's identity.

The main step of this transition is the token exchange. The application performs this token exchange by calling the `CreateTokenWithIAM` API operation in IAM Identity Center. Of course, that too is an AWS API call and requires an IAM principal to sign it. The IAM principal that makes this request is typically an IAM role that's associated with the application. For example, if the application runs on Amazon EC2, the `CreateTokenWithIAM` request is typically performed by the IAM role that's associated with the EC2 instance on which the application runs. The result of a successful `CreateTokenWithIAM` call is a new identity token, which will be recognized within AWS services.

The next step, before the application can call `GetDataAccess` on the directory user's behalf, is for the application to obtain an IAM session that includes the directory user's identity. The application does this with an AWS Security Token Service (AWS STS) `AssumeRole` request that also includes the IAM Identity Center token for the directory user as additional identity context. This additional context is what enables IAM Identity Center to propagate the directory user's identity to the next step. The IAM role that the application assumes is the role that will need IAM permissions to call the `GetDataAccess` operation.

Having assumed the identity bearer IAM role with the IAM Identity Center token for the directory user as additional context, the application now has everything it needs to make a signed request to `GetDataAccess` on behalf of the authenticated directory user.

Token propagation is based on the following steps:

Create an IAM Identity Center application

First, create a new application in IAM Identity Center. This application will use a template that allows IAM Identity Center to identify which type of application settings that you can use. The

command to create the application requires you to provide the IAM Identity Center instance Amazon Resource Name (ARN), an application name, and the application provider ARN. The application provider is the SAML or OAuth application provider that the application will use to make calls to IAM Identity Center.

To use the following example command, replace the *user input placeholders* with your own information:

```
aws sso-admin create-application \
 --instance-arn "arn:aws:sso:::instance/ssoins-ssoins-1234567890abcdef" \
 --application-provider-arn "arn:aws:sso::aws:applicationProvider/custom" \
 --name MyDataApplication
```

Response:

```
{
   "ApplicationArn": "arn:aws:sso::123456789012:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
}
```

Create a trusted token issuer

Now that you have your IAM Identity Center application, the next step is to configure a trusted token issuer that will be used to exchange your `IdToken` values from your IdP with IAM Identity Center tokens. In this step you need to provide the following items:

- The identity provider issuer URL
- The trusted token issuer name
- The claim attribute path
- The identity store attribute path
- The JSON Web Key Set (JWKS) retrieval option

The claim attribute path is the identity provider attribute that will be used to map to the identity store attribute. Normally, the claim attribute path is the email address of the user, but you can use other attributes to perform the mapping.

Create a file called `oidc-configuration.json` with the following information. To use this file, replace the *user input placeholders* with your own information.

```
{
  "OidcJwtConfiguration":
     {
      "IssuerUrl": "https://login.microsoftonline.com/a1b2c3d4-abcd-1234-b7d5-
b154440ac123/v2.0",
      "ClaimAttributePath": "preferred_username",
      "IdentityStoreAttributePath": "userName",
      "JwksRetrievalOption": "OPEN_ID_DISCOVERY"
     }
}
```

To create the trusted token issuer, run the following command. To use this example command, replace the *user input placeholders* with your own information.

```
aws sso-admin create-trusted-token-issuer \
  --instance-arn "arn:aws:sso:::instance/ssoins-1234567890abcdef" \
  --name MyEntraIDTrustedIssuer \
  --trusted-token-issuer-type OIDC_JWT \
  --trusted-token-issuer-configuration file://./oidc-configuration.json
```

Response

```
{
  "TrustedTokenIssuerArn": "arn:aws:sso::123456789012:trustedTokenIssuer/
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-1234-a1b2c3d41234"
}
```

Connect the IAM Identity Center application with the trusted token issuer

The trusted token issuer requires a few more configuration settings to work. Set the audience that the trusted token issuer will trust. The audience is the value inside the `IdToken` that's identified by the key and can be found in the identity provider settings. For example:

```
1234973b-abcd-1234-abcd-345c5a9c1234
```

Create a file named `grant.json` that contains the following content. To use this file, change the audience to match your identity provider settings and provide the trusted token issuer ARN that was returned by the previous command.

```
{
```

```
   "JwtBearer":
     {
       "AuthorizedTokenIssuers":
         [
           {
             "TrustedTokenIssuerArn": "arn:aws:sso::123456789012:trustedTokenIssuer/
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-1234-a1b2c3d41234",
               "AuthorizedAudiences":
                 [
                   "1234973b-abcd-1234-abcd-345c5a9c1234"
                 ]
            }
         ]
     }
 }
```

Run the following example command. To use this command, replace the *`user input placeholders`* with your own information.

```
aws sso-admin put-application-grant \
  --application-arn "arn:aws:sso::123456789012:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \
  --grant-type "urn:ietf:params:oauth:grant-type:jwt-bearer" \
  --grant file://./grant.json \
```

This command sets the trusted token issuer with configuration settings to trust the audience in the `grant.json` file and link this audience with the application created in the first step for exchanging tokens of the type `jwt-bearer`. The string `urn:ietf:params:oauth:grant-type:jwt-bearer` is not an arbitrary string. It is a registered namespace in OAuth JSON Web Token (JWT) assertion profiles. You can find more information about this namespace in RFC 7523.

Next, use the following command to set up which scopes the trusted token issuer will include when exchanging `IdToken` values from your identity provider. For S3 Access Grants, the value for the `--scope` parameter is `s3:access_grants:read_write`.

```
aws sso-admin put-application-access-scope \
  --application-arn "arn:aws:sso::111122223333:application/ssoins-
ssoins-111122223333abcdef/apl-abcd1234a1b2c3d" \
  --scope "s3:access_grants:read_write"
```

The last step is to attach a resource policy to the IAM Identity Center application. This policy will allow your application IAM role to make requests to the API operation `sso-oauth:CreateTokenWithIAM` and receive the `IdToken` values from IAM Identity Center.

Create a file named `authentication-method.json` that contains the following content. Replace *123456789012* with your account ID.

```
{
   "Iam":
       {
         "ActorPolicy":
             {
                "Version": "2012-10-17",
                    "Statement":
                    [
                        {
                           "Effect": "Allow",
                            "Principal":
                            {
                              "AWS": "arn:aws:iam::123456789012:role/webapp"
                            },
                           "Action": "sso-oauth:CreateTokenWithIAM",
                            "Resource": "*"
                        }
                    ]
                }
            }
        }
```

To attach the policy to the IAM Identity Center application, run the following command:

```
aws sso-admin put-application-authentication-method \
   --application-arn "arn:aws:sso::123456789012:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \
   --authentication-method-type IAM \
   --authentication-method file://./authentication-method.json
```

This completes the configuration settings for using S3 Access Grants with directory users through a web application. You can test this setup directly in the application or you can call the `CreateTokenWithIAM` API operation by using the following command from an allowed IAM role in the IAM Identity Center application policy:

```
aws sso-oidc create-token-with-iam \
   --client-id "arn:aws:sso::123456789012:application/ssoins-ssoins-1234567890abcdef/
apl-abcd1234a1b2c3d"  \
   --grant-type urn:ietf:params:oauth:grant-type:jwt-bearer \
   --assertion IdToken
```

The response will be similar to this:

```
{
    "accessToken": "<suppressed long string to reduce space>",
    "tokenType": "Bearer",
    "expiresIn": 3600,
    "refreshToken": "<suppressed long string to reduce space>",
    "idToken": "<suppressed long string to reduce space>",
    "issuedTokenType": "urn:ietf:params:oauth:token-type:refresh_token",
    "scope": [
      "sts:identity_context",
      "s3:access_grants:read_write",
      "openid",
      "aws"
    ]
}
```

If you decode the `IdToken` value that is encoded with base64, you can see the key-value pairs in JSON format. The key `sts:identity_context` contains the value that your application needs to send in the `sts:AssumeRole` request to include the identity information of the directory user. Here is an example of the `IdToken` decoded:

```
{
    "aws:identity_store_id": "d-996773e796",
    "sts:identity_context": "AQoJb3JpZ2luX2VjEOTtl;<SUPRESSED>",
    "sub": "83d43802-00b1-7054-db02-f1d683aacba5",
    "aws:instance_account": "123456789012",
    "iss": "https://identitycenter.amazonaws.com/ssoins-1234567890abcdef",
    "sts:audit_context": "AQoJb3JpZ2luX2VjEOT<SUPRESSED>==",
    "aws:identity_store_arn": "arn:aws:identitystore::232642235904:identitystore/
d-996773e796",
    "aud": "abcd12344U0gi7n4Yyp0-WV1LWNlbnRyYWwtMQ",
    "aws:instance_arn": "arn:aws:sso:::instance/ssoins-6987d7fb04cf7a51",
    "aws:credential_id": "EXAMPLEHI5glPh40y9TpApJn8...",
    "act": {
```

```
       "sub": "arn:aws:sso::232642235904:trustedTokenIssuer/
ssoins-6987d7fb04cf7a51/43b4a822-1020-7053-3631-cb2d3e28d10e"
    },
    "auth_time": "2023-11-01T20:24:28Z",
    "exp": 1698873868,
    "iat": 1698870268
}
```

You can get the value from `sts:identity_context` and pass this information in an `sts:AssumeRole` call. The following is a CLI example of the syntax. The role to be assumed is a temporary role with permissions to invoke `s3:GetDataAccess`.

```
aws sts assume-role \
   --role-arn "arn:aws:iam::123456789012:role/temp-role" \
   --role-session-name "TempDirectoryUserRole" \
   --provided-contexts ProviderArn="arn:aws:iam::aws:contextProvider/
IdentityCenter",ContextAssertion="value from sts:identity_context"
```

You can now use the credentials received from this call to invoke the `s3:GetDataAccess` API operation and receive the final credentials with access to your S3 resources.

Getting started with S3 Access Grants

Amazon S3 Access Grants is an Amazon S3 feature that provides a scalable access control solution for your S3 data. S3 Access Grants is an S3 credential vendor, meaning that you register with S3 Access Grants your list of grants and at what level. Thereafter, when users or clients need access to your S3 data, they first ask S3 Access Grants for credentials. If there is a corresponding grant that authorizes access, S3 Access Grants vends temporary, least-privilege access credentials. The users or clients can then use S3 Access Grants vended credentials to access your S3 data. With that in mind, if your S3 data requirements mandate a complex or large permission configuration, you can use S3 Access Grants to scale S3 data permissions for users, groups, roles, and applications.

For most use cases, you can manage access control for your S3 data by using AWS Identity and Access Management (IAM) with bucket policies or IAM identity-based policies.

However, if you have complex S3 access control requirements, such as the following, you could benefit greatly from using S3 Access Grants:

- You are running into the bucket policy size limit of 20 KB.

- You grant human identities, for example, Microsoft Entra ID (formerly Azure Active Directory), Okta, or Ping users and groups, access to S3 data for analytics and big data.
- You must provide cross-account access without making frequent updates to IAM policies.
- Your data is unstructured and object-level rather than structured, in row and column format.

The S3 Access Grants workflow is as follows:

Steps	Description
1	Create an S3 Access Grants instance To get started, initiate an S3 Access Grants instance that will contain your individual access grants.
2	Register a location Second, register an S3 data location (such as the default, `s3://`) and then specify a default IAM role that S3 Access Grants assumes when providing access to the S3 data location. You can also add custom locations to specific buckets or prefixes and map those to custom IAM roles.
3	Create grants Create individual permission grants. Specify in these permissio n grants the registered S3 location, the scope of data access within the location, the identity of the grantee, and their access level (`READ`, `WRITE`, or `READWRITE`).
4	Request access to S3 data When users, applications, and AWS services want to access S3 data, they first make an access request. S3 Access Grants determines if the request should be authorized. If there is a corresponding grant that authorizes access, S3 Access Grants uses the registered location's IAM role that's associated with that grant to vend temporary credentials back to the request er.

Steps	Description
5	Access S3 data Applications use the temporary credentials vended by S3 Access Grants to access S3 data.

Working with S3 Access Grants instances

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've added your corporate identity directory to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

Topics

- Create an S3 Access Grants instance
- Get the details of an S3 Access Grants instance
- List your S3 Access Grants instances
- Associate or disassociate your IAM Identity Center instance
- Delete an S3 Access Grants instance

Create an S3 Access Grants instance

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've added your corporate identity directory to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

You can create an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must first create an S3 Access Grants instance in the same AWS Region as your S3 data.

Prerequisites

If you want to grant access to your S3 data by using identities from your corporate directory, add your corporate identity directory to AWS IAM Identity Center. If you're not yet ready to do so, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

To create an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Access Grants**.
4. On the **S3 Access Grants** page, choose **Create S3 Access Grants instance**.
    a. In **Step 1** of the **Set up Access Grants instance** wizard, verify that you want to create the instance in the current AWS Region. Make sure that this is the same AWS Region where your S3 data is located. You can create one S3 Access Grants instance per AWS Region per account.
    b. (Optional) If you've added your corporate identity directory to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance.

To do so, select **Add IAM Identity Center instance in *region***. Then enter the IAM Identity Center instance Amazon Resource Name (ARN).

If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

c. To create the S3 Access Grants instance, choose **Next**. To register a location, see Step 2 - register a location.

5. If **Next** or **Create S3 Access Grants instance** is disabled:

Cannot create instance

- You might already have an S3 Access Grants instance in the same AWS Region. In the left navigation pane, choose **Access Grants**. On the **S3 Access Grants** page, scroll down to the **S3 Access Grants instance in your account** section o determine if an instance already exists.
- You might not have the `s3:CreateAccessGrantsInstance` permission which is required to create an S3 Access Grants instance. Contact your account administrator. For additional permissions that are required if you are associating an IAM Identity Center instance, with your S3 Access Grants instance, see CreateAccessGrantsInstance .

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example Create an S3 Access Grants instance

```
aws s3control create-access-grants-instance \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00",
    "AccessGrantsInstanceId": "default",
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default"
```

```
}
```

Using the REST API

You can use the Amazon S3 REST API to create an S3 Access Grants instance. For information on the REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- AssociateAccessGrantsIdentityCenter
- CreateAccessGrantsInstance
- DeleteAccessGrantsInstance
- DissociateAccessGrantsIdentityCenter
- GetAccessGrantsInstance
- GetAccessGrantsInstanceForPrefix
- GetAccessGrantsInstanceResourcePolicy
- ListAccessGrantsInstances
- PutAccessGrantsInstanceResourcePolicy

Using the AWS SDKs

This section provides an example of how to create an S3 Access Grants instance by using the AWS SDKs.

Java

This example creates the S3 Access Grants instance, which serves as a container for your individual access grants. You can have one S3 Access Grants instance per AWS Region in your account. The response includes the instance ID `default` and an Amazon Resource Name (ARN) that's generated for your S3 Access Grants instance.

Example Create an S3 Access Grants instance request

```
public void createAccessGrantsInstance() {
CreateAccessGrantsInstanceRequest createRequest =
 CreateAccessGrantsInstanceRequest.builder().accountId("111122223333").build();
CreateAccessGrantsInstanceResponse createResponse =
 s3Control.createAccessGrantsInstance(createRequest);LOGGER.info("CreateAccessGrantsInstance
 " + createResponse);
```

```
}
```

Response:

```
CreateAccessGrantsInstanceResponse(
CreatedAt=2023-06-07T01:46:20.507Z,
AccessGrantsInstanceId=default,
AccessGrantsInstanceArn=arn:aws:s3:us-east-2:111122223333:access-grants/default)
```

Get the details of an S3 Access Grants instance

You can get the details of your Amazon S3 Access Grants instance in a particular AWS Region. You can get the details of your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To get the details of an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example– Get the details of an S3 Access Grants instance

```
aws s3control get-access-grants-instance \
 --account-id 111122223333 \
```

```
 --region us-east-2
```

Response:

```
{
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default",
    "AccessGrantsInstanceId": "default",
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"
}
```

Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetAccessGrantsInstance
- GetAccessGrantsInstanceForPrefix

Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

Example– Get an S3 Access Grants instance

```
public void getAccessGrantsInstance() {
GetAccessGrantsInstanceRequest getRequest = GetAccessGrantsInstanceRequest.builder()
.accountId("111122223333")
.build();
GetAccessGrantsInstanceResponse getResponse =
 s3Control.getAccessGrantsInstance(getRequest);
LOGGER.info("GetAccessGrantsInstanceResponse: " + getResponse);
}
```

Response:

```
GetAccessGrantsInstanceResponse(
AccessGrantsInstanceArn=arn:aws:s3:us-east-2: 111122223333:access-grants/default,
CreatedAt=2023-06-07T01:46:20.507Z)
```

List your S3 Access Grants instances

You can list your S3 Access Grants instances, including the instances that have been shared with you through AWS Resource Access Manager (AWS RAM).

You can list your S3 Access Grants instances by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To list your S3 Access Grants instances

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example– List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per AWS Region. This action also lists other cross-account S3 Access Grants instances that your account has access to.

```
aws s3control list-access-grants-instances \
```

```
 --account-id 111122223333 \
 --region us-east-2
```

Response:

```
{
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default",
    "AccessGrantsInstanceId": "default",
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"
}
```

Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- ListAccessGrantsInstances

Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

Example– List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per Region. This action can also list other cross-account S3 Access Grants instances that your account has access to.

```
public void listAccessGrantsInstances() {
ListAccessGrantsInstancesRequest listRequest =
 ListAccessGrantsInstancesRequest.builder()
.accountId("111122223333")
.build();
ListAccessGrantsInstancesResponse listResponse =
 s3Control.listAccessGrantsInstances(listRequest);
```

```
LOGGER.info("ListAccessGrantsInstancesResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsInstancesResponse(
AccessGrantsInstancesList=[
ListAccessGrantsInstanceEntry(
AccessGrantsInstanceId=default,
AccessGrantsInstanceArn=arn:aws:s3:us-east-2:111122223333:access-grants/default,
CreatedAt=2023-06-07T04:28:11.728Z
)
]
)
```

Associate or disassociate your IAM Identity Center instance

In Amazon S3 Access Grants, you can associate the AWS IAM Identity Center instance of your corporate identity directory with an S3 Access Grants instance. After you do so, you can create access grants for your corporate directory users and groups, in addition to AWS Identity and Access Management (IAM) users and roles.

If you no longer want to create access grants for your corporate directory users and groups, you can disassociate your IAM Identity Center instance from your S3 Access Grants instance.

You can associate or disassociate an IAM Identity Center instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

Before you associate your IAM Identity Center instance with your S3 Access Grants instance, you must add your corporate identity directory to IAM Identity Center. For more information, see the section called “S3 Access Grants and corporate directory identities”.

To associate an IAM Identity Center instance with an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.

3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, in the **IAM Identity Center** section, choose to either **Add** an IAM Identity Center instance or **Deregister** an already associated IAM Identity Center instance.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example– Associate an IAM Identity Center instance with an S3 Access Grants instance

```
aws s3control associate-access-grants-identity-center \
 --account-id 111122223333 \
 --identity-center-arn arn:aws:sso:::instance/ssoins-1234a567bb89012c \
 --profile access-grants-profile \
 --region eu-central-1

// No response body
```

Example– Disassociate an IAM Identity Center instance from an S3 Access Grants instance

```
aws s3control dissociate-access-grants-identity-center \
 --account-id 111122223333 \
 --profile access-grants-profile \
 --region eu-central-1

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for managing the association between an IAM Identity Center instance and an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- AssociateAccessGrantsIdentityCenter
- DissociateAccessGrantsIdentityCenter

Delete an S3 Access Grants instance

You can delete an Amazon S3 Access Grants instance from an AWS Region in your account. However, before you can delete an S3 Access Grants instance, you must first do the following:

- Delete all resources within the S3 Access Grants instance, including all grants and locations. For more information, see Delete a grant and Delete a location.
- If you've associated an AWS IAM Identity Center instance with your S3 Access Grants instance, you must disassociate the IAM Identity Center instance. For more information, see Associate or disassociate your IAM Identity Center instance.

> **Important**
>
> If you delete an S3 Access Grants instance, the deletion is permanent and can't be undone. All grantees that were given access through the grants in this S3 Access Grants instance will lose access to your S3 data.

You can delete an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the instance details page, choose **Delete instance**.
6. In the dialog box that appears, choose **Delete**. This action can't be undone.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

> **Note**
>
> Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

Example– Delete an S3 Access Grants instance

```
aws s3control delete-access-grants-instance \
--account-id 111122223333 \
--profile access-grants-profile \
--region us-east-2 \
--endpoint-url https://s3-control.us-east-2.amazonaws.com \

 // No response body
```

Using the REST API

For information about the Amazon S3 REST API support for deleting an S3 Access Grants instance, see DeleteAccessGrantsInstance in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to delete an S3 Access Grants instance by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

> **Note**
>
> Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an

IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

Example– Delete an S3 Access Grants instance

```
public void deleteAccessGrantsInstance() {
DeleteAccessGrantsInstanceRequest deleteRequest =
 DeleteAccessGrantsInstanceRequest.builder()
.accountId("111122223333")
.build();
DeleteAccessGrantsInstanceResponse deleteResponse =
 s3Control.deleteAccessGrantsInstance(deleteRequest);
LOGGER.info("DeleteAccessGrantsInstanceResponse: " + deleteResponse);
}
```

Working with S3 Access Grants locations

After you create an Amazon S3 Access Grants instance in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location (`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

You can register a location, view a location's details, edit a location, and delete a location.

Note

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see Create grants.

Topics

- Register a location
- View the details of a registered location

- Update a registered location
- Delete a registered location

Register a location

After you create an Amazon S3 Access Grants instance in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location (`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

Recommended use case

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in that AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

Complex access-management use cases

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the *`amzn-s3-demo-bucket`* is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

When you register a location, you must also specify the IAM role that S3 Access Grants assumes to vend temporary credentials and to scope the permissions for a specific grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

S3 URI	IAM role	Description
`s3://`	*`Default-IAM-role`*	The default location, `s3://`, includes all buckets in the AWS Region.
`s3://`*`amzn-s3-demo-bucket1`*`/`	*`IAM-role-For-bucket`*	This location includes all objects in the specified bucket.
`s3://`*`amzn-s3-demo-bucket1`*`/`*`prefix-name`*	*`IAM-role-For-prefix`*	This location includes all objects in the bucket with an object key name that starts with this prefix.

Before you can register a specific bucket or prefix, make sure that you do the following:

- Create one or more buckets that contain the data that you want to grant access to. These buckets must be located in the same AWS Region as your S3 Access Grants instance. For more information, see Creating a bucket.

  Adding a prefix is an optional step. Prefixes are strings at the beginning of an object key name. You can use them to organize objects in your bucket as well as for access management. To add a prefix to a bucket, see Creating object key names.
- Create an IAM role that has permission to access your S3 data in the AWS Region. For more information, see Creating IAM roles in the *AWS IAM Identity Center user guide*.
- In the IAM role trust policy, give the S3 Access Grants service (`access-grants.s3.amazonaws.com`) principal access to the IAM role that you created. To do so, you can create a JSON file that contains the following statements. To add the trust policy to your account, see Create a role using custom trust policies.

  TestRolePolicy.json

  JSON

```
{
  "Version":"2012-10-17",
    "Statement": [
```

```
    {
      "Sid": "TestRolePolicy",
      "Effect": "Allow",
      "Principal": {
        "Service": "access-grants.s3.amazonaws.com"
      },
      "Action": [
        "sts:AssumeRole",
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
          "aws:SourceArn": "arn:aws:s3::111122223333:access-grants/default"
        }
      }
    }
  ]
}
```

Alternatively, for an IAM Identity Center use case, use the following policy which includes a second statement:

- Create an IAM policy to attach Amazon S3 permissions to the IAM role that you created. See the following example `iam-policy.json` file and replace the *`user input placeholders`* with your own information.

> **Note**
>
> - If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example includes the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.
> - You can restrict the IAM role to access S3 data only if the credentials are vended by S3 Access Grants. This example shows you how to add a `Condition` statement for a specific S3 Access Grants instance. To use this `Condition`, replace the S3 Access Grants instance ARN in the `Condition` statement with your S3 Access Grants instance ARN. This has the format: `arn:aws:s3:`*`region`*`:`*`accountId`*`:access-grants/default`

iam-policy.json

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
         "Sid": "ObjectLevelReadPermissions",
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:GetObjectAcl",
            "s3:GetObjectVersionAcl",
            "s3:ListMultipartUploadParts"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:region:accountId:access-
grants/default"]
            }
        }
      },
      {
         "Sid": "ObjectLevelWritePermissions",
         "Effect":"Allow",
         "Action":[
            "s3:PutObject",
            "s3:PutObjectAcl",
            "s3:PutObjectVersionAcl",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion",
            "s3:AbortMultipartUpload"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
```

```
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS
 Region:accountId:access-grants/default"]
            }
         }
      },
      {
         "Sid": "BucketLevelReadPermissions",
         "Effect":"Allow",
         "Action":[
            "s3:ListBucket"
         ],
         "Resource":[
            "arn:aws:s3:::*"
         ],
         "Condition":{
            "StringEquals": { "aws:ResourceAccount": "accountId" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS
 Region:accountId:access-grants/default"]
            }
         }
      },
   //Optionally add the following section if you use SSE-KMS encryption
      {
         "Sid": "KMSPermissions",
         "Effect":"Allow",
         "Action":[
            "kms:Decrypt",
            "kms:GenerateDataKey"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

You can register a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

> **Note**
>
> After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see Create grants.

Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must have at least one registered location.

To register a location in your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

   If you're using S3 Access Grants instance for the first time, make sure that you have completed Step 1 - create an S3 Access Grants instance and navigated to **Step 2** of the **Set up Access Grants instance** wizard. If you already have an S3 Access Grants instance, choose **View details**, and then from the **Locations** tab, choose **Register location**.

   a. For the **Location scope**, choose **Browse S3** or enter the S3 URI path to the location that you want to register. For S3 URI formats, see the location formats table. After you enter a URI, you can choose **View** to browse the location.

   b. For the **IAM role**, choose one of the following:

   - **Choose from existing IAM roles**

     Choose an IAM role from the dropdown list. After you choose a role, choose **View** to make sure that this role has the necessary permissions to manage the location that you're registering. Specifically, make sure that this role grants S3 Access Grants the permissions `sts:AssumeRole` and `sts:SetSourceIdentity`.

   - **Enter IAM role ARN**

Navigate to the IAM Console. Copy the Amazon Resource Name (ARN) of the IAM role and paste it in this box.

c. To finish, choose **Next** or **Register location**.

4. Troubleshooting:

Cannot register location

- The location might already be registered.

  You might not have the `s3:CreateAccessGrantsLocation` permission to register locations. Contact your account administrator.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *`user input placeholders`* with your own information.

Example Create a resource policy

Create a policy that allows S3 Access Grants to assume the IAM role. To do so, you can create a JSON file that contains the following statements. To add the resource policy to your account, see Create and attach your first customer managed policy.

TestRolePolicy.json

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1234567891011",
      "Action": ["sts:AssumeRole", "sts:SetSourceIdentity"],
```

```
      "Effect": "Allow",
      "Principal": {"Service": "access-grants.s3.amazonaws.com"}
    }
  ]
}
```

Example Create the role

Run the following IAM command to create the role.

```
aws iam create-role --role-name accessGrantsTestRole \
 --region us-east-2 \
 --assume-role-policy-document file://TestRolePolicy.json
```

Running the `create-role` command returns the policy:

```
{
    "Role": {
        "Path": "/",
        "RoleName": "accessGrantsTestRole",
        "RoleId": "AROASRDGX4WM4GH55GIDA",
        "Arn": "arn:aws:iam::111122223333:role/accessGrantsTestRole",
        "CreateDate": "2023-05-31T18:11:06+00:00",
        "AssumeRolePolicyDocument": {
            "Version": "2012-10-17",
            "Statement": [
                {
                    "Sid": "Stmt1685556427189",
                    "Action": [
                        "sts:AssumeRole",
                        "sts:SetSourceIdentity"
                    ],
                    "Effect": "Allow",
                    "Principal": {
                        "Service":"access-grants.s3.amazonaws.com"
                    }
                }
            ]
        }
    }
}
```

Example

Create an IAM policy to attach Amazon S3 permissions to the IAM role. See the following example `iam-policy.json` file and replace the *`user input placeholders`* with your own information.

> **Note**
>
> If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example adds the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.
> To make sure that the IAM role can only be used to access data in S3 if the credentials are vended out by S3 Access Grants, this example shows you how to add a `Condition` statement that specifies the S3 Access Grants instance (`s3:AccessGrantsInstance:`*`InstanceArn`*) in your IAM policy. When using following example policy, replace the *`user input placeholders`* with your own information.

iam-policy.json

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
         "Sid": "ObjectLevelReadPermissions",
         "Effect": "Allow",
         "Action": [
            "s3:GetObject",
            "s3:GetObjectVersion",
            "s3:GetObjectAcl",
            "s3:GetObjectVersionAcl",
            "s3:ListMultipartUploadParts"
         ],
         "Resource": [
            "arn:aws:s3:::*"
         ],
         "Condition": {
```

```
            "StringEquals": { "aws:ResourceAccount": "111122223333" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:us-east-1::access-
grants/default"]
            }
        }
      },
      {
         "Sid": "ObjectLevelWritePermissions",
         "Effect": "Allow",
         "Action": [
            "s3:PutObject",
            "s3:PutObjectAcl",
            "s3:PutObjectVersionAcl",
            "s3:DeleteObject",
            "s3:DeleteObjectVersion",
            "s3:AbortMultipartUpload"
         ],
         "Resource": [
            "arn:aws:s3:::*"
         ],
         "Condition": {
            "StringEquals": { "aws:ResourceAccount": "111122223333" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:us-east-1::access-
grants/default"]
            }
         }
      },
      {
         "Sid": "BucketLevelReadPermissions",
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::*"
         ],
         "Condition": {
            "StringEquals": { "aws:ResourceAccount": "111122223333" },
            "ArnEquals": {
                "s3:AccessGrantsInstanceArn": ["arn:aws:s3:us-east-1::access-
grants/default"]
            }
```

```
            }
        },
        {
            "Sid": "KMSPermissions",
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "s3.us-east-1.amazonaws.com"
                }
            }
        }
    ]
}
```

Example

Run the following command:

```
aws iam put-role-policy \
--role-name accessGrantsTestRole \
--policy-name accessGrantsTestRole \
--policy-document file://iam-policy.json
```

Example Register the default location

```
aws s3control create-access-grants-location \
 --account-id 111122223333 \
 --location-scope s3:// \
 --iam-role-arn arn:aws:iam::111122223333:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
```

```
    "AccessGrantsLocationId": "default",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
    "LocationScope": "s3://"
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Example Register a custom location

```
aws s3control create-access-grants-location \
 --account-id 111122223333 \
 --location-scope s3://DOC-BUCKET-EXAMPLE/ \
 --iam-role-arn arn:aws:iam::123456789012:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://DOC-BUCKET-EXAMPLE/",
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Using the REST API

For information about Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- CreateAccessGrantsLocation
- DeleteAccessGrantsLocation
- GetAccessGrantsLocation
- ListAccessGrantsLocations
- UpdateAccessGrantsLocation

Using the AWS SDKs

This section provides examples of how to register locations by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *user input placeholders* with your own information.

Example Register a default location

Request:

```
public void createAccessGrantsLocation() {
CreateAccessGrantsLocationRequest createRequest =
 CreateAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.locationScope("s3://")
.iamRoleArn("arn:aws:iam::123456789012:role/accessGrantsTestRole")
.build();
CreateAccessGrantsLocationResponse createResponse =
 s3Control.createAccessGrantsLocation(createRequest);
LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);
}
```

Response:

```
CreateAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:11.027Z,
AccessGrantsLocationId=default,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/default,
LocationScope=s3://,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

Example Register a custom location

Request:

```
public void createAccessGrantsLocation() {
CreateAccessGrantsLocationRequest createRequest =
 CreateAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.locationScope("s3://DOC-BUCKET-EXAMPLE/")
.iamRoleArn("arn:aws:iam::111122223333:role/accessGrantsTestRole")
.build();
CreateAccessGrantsLocationResponse createResponse =
 s3Control.createAccessGrantsLocation(createRequest);
LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);
}
```

Response:

```
CreateAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=18cfe6fb-eb5a-4ac5-aba9-8d79f04c2012,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/18cfe6fb-eb5a-4ac5-aba9-8d79f04c2666,
LocationScope= s3://test-bucket-access-grants-user123/,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

View the details of a registered location

You can get the details of a location that's registered in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view the locations registered in your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.

5. On the details page for the instance, choose the **Locations** tab.
6. Find the registered location that you want to view. To filter the list of registered locations, use the search box.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example– Get the details of a registered location

```
aws s3control get-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id default
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "default",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Example– List all of the locations that are registered in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally use the `--location-scope s3://bucket-and-or-prefix` parameter.

```
aws s3control list-access-grants-locations \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{"AccessGrantsLocationsList": [
```

```
  {
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "default",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/default",
    "LocationScope": "s3://"
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
     },
  {
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixA*",
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
     }
   ]
  }
```

Using the REST API

For information about the Amazon S3 REST API support for getting the details of a registered location or listing all of the locations that are registered with an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetAccessGrantsLocation
- ListAccessGrantsLocations

Using the AWS SDKs

This section provides examples of how to get the details of a registered location or list all of the registered locations in an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

Example– Get the details of a registered location

```
public void getAccessGrantsLocation() {
```

```
GetAccessGrantsLocationRequest getAccessGrantsLocationRequest =
 GetAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("default")
.build();
GetAccessGrantsLocationResponse getAccessGrantsLocationResponse =
 s3Control.getAccessGrantsLocation(getAccessGrantsLocationRequest);
LOGGER.info("GetAccessGrantsLocationResponse: " + getAccessGrantsLocationResponse);
}
```

Response:

```
GetAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=default,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/default,
LocationScope= s3://,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
```

Example– List all registered locations in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally pass an S3 URI, such as `s3://bucket-and-or-prefix`, in the `LocationScope` parameter.

```
public void listAccessGrantsLocations() {

ListAccessGrantsLocationsRequest listRequest =
 ListAccessGrantsLocationsRequest.builder()
.accountId("111122223333")
.build();

ListAccessGrantsLocationsResponse listResponse =
 s3Control.listAccessGrantsLocations(listRequest);
LOGGER.info("ListAccessGrantsLocationsResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsLocationsResponse(
AccessGrantsLocationsList=[
```

```
ListAccessGrantsLocationsEntry(
CreatedAt=2023-06-07T04:35:11.027Z,
AccessGrantsLocationId=default,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/default,
LocationScope=s3://,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
),
ListAccessGrantsLocationsEntry(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb456,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
location/635f1139-1af2-4e43-8131-a4de006eb888,
LocationScope=s3://amzn-s3-demo-bucket/prefixA*,
IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
)
]
)
```

Update a registered location

You can update the AWS Identity and Access Management (IAM) role of a location that's registered in your Amazon S3 Access Grants instance. For each new IAM role that you use to register a location in S3 Access Grants, be sure to give the S3 Access Grants service principal (`access-grants.s3.amazonaws.com`) access to this role. To do this, add an entry for the new IAM role in the same trust policy JSON file that you used when you first registered the location.

You can update a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To update the IAM role of a location registered with your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.

5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the options button next to the registered location that you want to update.
8. Update the IAM role, and then choose **Save changes**.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example– Update the IAM role of a registered location

```
aws s3control update-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id 635f1139-1af2-4e43-8131-a4de006eb999 \
--iam-role-arn arn:aws:iam::777788889999:role/accessGrantsTestRole
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb999",
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:777788889999:access-grants/
default/location/635f1139-1af2-4e43-8131-a4de006eb888",
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixB*",
    "IAMRoleArn": "arn:aws:iam::777788889999:role/accessGrantsTestRole"
}
```

Using the REST API

For information on the Amazon S3 REST API support for updating a location in an S3 Access Grants instance, see UpdateAccessGrantsLocation in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to update the IAM role of a registered location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Example– Update the IAM role of a registered location

```
public void updateAccessGrantsLocation() {
UpdateAccessGrantsLocationRequest updateRequest =
 UpdateAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("635f1139-1af2-4e43-8131-a4de006eb999")
.iamRoleArn("arn:aws:iam::777788889999:role/accessGrantsTestRole")
.build();
UpdateAccessGrantsLocationResponse updateResponse =
 s3Control.updateAccessGrantsLocation(updateRequest);
LOGGER.info("UpdateAccessGrantsLocationResponse: " + updateResponse);
}
```

Response:

```
UpdateAccessGrantsLocationResponse(
CreatedAt=2023-06-07T04:35:10.027Z,
AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb999,
AccessGrantsLocationArn=arn:aws:s3:us-east-2:777788889999:access-grants/default/
location/635f1139-1af2-4e43-8131-a4de006eb888,
LocationScope=s3://amzn-s3-demo-bucket/prefixB*,
IAMRoleArn=arn:aws:iam::777788889999:role/accessGrantsTestRole
)
```

Delete a registered location

You can delete a location registration from an Amazon S3 Access Grants instance. Deleting the location deregisters it from the S3 Access Grants instance.

Before you can remove a location registration from an S3 Access Grants instance, you must delete all of the grants that are associated with this location. For information about how to delete grants, see Delete a grant.

You can delete a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete a location registration from your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the option button next to the registered location that you want to delete.
8. Choose **Deregister**.
9. A dialog box appears that warns you that this action can't be undone. To delete the location, choose **Deregister**.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example– Delete a location registration

```
aws s3control delete-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id  a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
 // No response body
```

Using the REST API

For information about the Amazon S3 REST API support for deleting a location from an S3 Access Grants instance, see DeleteAccessGrantsLocation in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how to delete a location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Example– Delete a location registration

```
public void deleteAccessGrantsLocation() {
DeleteAccessGrantsLocationRequest deleteRequest =
 DeleteAccessGrantsLocationRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLE11111")
.build();
DeleteAccessGrantsLocationResponse deleteResponse =
 s3Control.deleteAccessGrantsLocation(deleteRequest);
LOGGER.info("DeleteAccessGrantsLocationResponse: " + deleteResponse);
}
```

Response:

```
DeleteAccessGrantsLocationResponse()
```

Working with grants in S3 Access Grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you register at least one location in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you associated with your S3 Access Grants instance. For more information, see S3 Access Grants and corporate directory

identities. To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, `a1b2c3d4-5678-90ab-cdef-EXAMPLE11111`. For more information about how to use IAM Identity Center to view user information, see View user and group assignments in the *AWS IAM Identity Center user guide*.

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket. This can be any string of allowed characters, for example, object key names in your bucket that start with the `engineering/` prefix.

Topics

- Create grants
- View a grant
- Delete a grant

Create grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you register at least one location in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you associated with your S3 Access Grants instance. For more information, see S3 Access Grants and corporate directory identities. To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, `a1b2c3d4-5678-90ab-cdef-EXAMPLE11111`. For more information about how to use IAM Identity Center to view user information, see View user and group assignments in the *AWS IAM Identity Center user guide*.

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket.

This can be any string of allowed characters, for example, object key names in your bucket that start with the `engineering/` prefix.

Subprefix

When granting access to a registered location, you can use the `Subprefix` field to narrow the scope of access to a subset of the location scope. If the registered location that you choose for the grant is the default S3 path (`s3://`), you must narrow the grant scope. You cannot create an access grant for the default location (`s3://`), which would give the grantee access to every bucket in an AWS Region. Instead, you must narrow the grant scope to one of the following:

- A bucket: `s3://`*`bucket`*`/*`
- A prefix within a bucket: `s3://`*`bucket`*`/`*`prefix`*`*`
- A prefix within a prefix: `s3://`*`bucket`*`/`*`prefixA`*`/`*`prefixB`*`*`
- An object: `s3://`*`bucket`*`/`*`object-key-name`*

If you are creating an access grant where the registered location is a bucket, you can pass one of the following in the `Subprefix` field to narrow the grant scope:

- A prefix within the bucket: *`prefix`*`*`
- A prefix within a prefix: *`prefixA/prefixB`*`*`
- An object: */`*`object-key-name`*

After you create the grant, the grant scope that's displayed in the Amazon S3 console or the `GrantScope` that is returned in the API or AWS Command Line Interface (AWS CLI) response is the result of concatenating the location path with the `Subprefix`. Make sure that this concatenated path maps correctly to the S3 bucket, prefix, or object to which you want to grant access.

Note

- If you need to create an access grant that grants access to only one object, you must specify that the grant type is for an object. To do this in an API call or a CLI command, pass the `s3PrefixType` parameter with the value `Object`. In the Amazon S3 console, when you create the grant, after you select a location, under **Grant Scope**, select the **Grant scope is an object** checkbox.

- You cannot create a grant to a bucket if the bucket does not yet exist. However, you can create a grant to a prefix that does not yet exist.
- For the maximum number of grants that you can create in your S3 Access Grants instance, see S3 Access Grants limitations.

You can create an access grant by using the Amazon S3 console, AWS CLI, the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

   If you're using the S3 Access Grants instance for the first time, make sure that you have completed Step 2 - register a location and navigated to **Step 3** of the **Set up Access Grants instance** wizard. If you already have an S3 Access Grants instance, choose **View details**, and then from the **Grants** tab, choose **Create grant**.

   a. In the **Grant scope** section, select or enter a registered location.

      If you selected the default `s3://` location, use the **Subprefix** box to can narrow the scope of the access grant. For more information, see Subprefix. If you're granting access only to an object, select **Grant scope is an object**.

   b. Under **Permissions and access**, select the **Permission** level, either **Read**, **Write**, or both.

      Then choose the **Grantee type**. If you have added your corporate directory to IAM Identity Center and associated this IAM Identity Center instance with your S3 Access Grants instance, you can choose **Directory identity from IAM Identity Center**. If you choose this option, get the ID of the user or group from IAM Identity Center and enter it in this section.

If the **Grantee type** is an IAM user or role, choose **IAM principal**. Under **IAM principal type**, choose **User** or **Role**. Then, under **IAM principal user**, either choose from the list or enter the identity's ID.

c. To create the S3 Access Grants grant, choose **Next** or **Create grant**.

4. If **Next** or **Create grant** is disabled:

Cannot create grant

- You might need to register a location first in your S3 Access Grants instance.
- You might not have the `s3:CreateAccessGrant` permission to create an access grant. Contact your account administrator.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following examples show how to create an access grant request for an IAM principal and how to create an access grant request for a corporate directory user or group.

To use the following example commands, replace the *`user input placeholders`* with your own information.

> **Note**
>
> If you're creating an access grant that grants access to only one object, include the required parameter `--s3-prefix-type Object`.

Example Create an access grant request for an IAM principal

```
aws s3control create-access-grant \
--account-id 111122223333 \
--access-grants-location-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222 \
--access-grants-location-configuration S3SubPrefix=prefixB* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::123456789012:user/data-consumer-3
```

Example Create an access grant response

```
{"CreatedAt": "2023-05-31T18:41:34.663000+00:00",
    "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "Grantee": {
        "GranteeType": "IAM",
        "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
    },
    "AccessGrantsLocationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "AccessGrantsLocationConfiguration": {
        "S3SubPrefix": "prefixB*"
    },
    "GrantScope": "s3://amzn-s3-demo-bucket/prefix*",
    "Permission": "READ"
}
```

Create an access grant request for a directory user or group

To create an access grant request for a directory user or group, you must first get the GUID for the directory user or group by running one of the following commands.

Example Get a GUID for a directory user or group

You can find the GUID of an IAM Identity Center user through the IAM Identity Center console or by using the AWS CLI or AWS SDKs. The following command lists the users in he specified IAM Identity Center instance, with their names and identifiers.

```
aws identitystore list-users --identity-store-id d-1a2b3c4d1234
```

This command lists the groups in the specified IAM Identity Center instance.

```
aws identitystore list-groups --identity-store-id d-1a2b3c4d1234
```

Example Create an access grant for a directory user or group

This command is similar to creating a grant for IAM users or roles, except the grantee type is `DIRECTORY_USER` or `DIRECTORY_GROUP`, and the grantee identifier is the GUID for the directory user or group.

```
aws s3control create-access-grant \
--account-id 123456789012 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix="amzn-s3-demo-bucket/rafael/*" \
--permission READWRITE \
--grantee GranteeType=DIRECTORY_USER,GranteeIdentifier=83d43802-00b1-7054-db02-
f1d683aacba5 \
```

Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- CreateAccessGrant
- DeleteAccessGrant
- GetAccessGrant
- ListAccessGrants

Using the AWS SDKs

This section provides examples of how to create an access grant by using the AWS SDKs.

Java

To use the following example, replace the *`user input placeholders`* with your own information:

> **Note**
>
> If you are creating an access grant that grants access to only one object, include the required parameter `.s3PrefixType(S3PrefixType.Object)`.

Example Create an access grant request

```
public void createAccessGrant() {
CreateAccessGrantRequest createRequest = CreateAccessGrantRequest.builder()
.accountId("111122223333")
.accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaa")
```

```
.permission("READ")
.accessGrantsLocationConfiguration(AccessGrantsLocationConfiguration.builder().s3SubPrefix("
.grantee(Grantee.builder().granteeType("IAM").granteeIdentifier("arn:aws:iam::111122223333:u
data-consumer-3").build())
.build();
CreateAccessGrantResponse createResponse =
 s3Control.createAccessGrant(createRequest);
LOGGER.info("CreateAccessGrantResponse: " + createResponse);
}
```

Example Create an access grant response

```
CreateAccessGrantResponse(
CreatedAt=2023-06-07T05:20:26.330Z,
AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,
AccessGrantArn=arn:aws:s3:us-east-2:444455556666:access-grants/default/grant/
a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,
Grantee=Grantee(
GranteeType=IAM,
GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3
),
AccessGrantsLocationId=a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaa,
AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(
S3SubPrefix=prefixB*
),
GrantScope=s3://amzn-s3-demo-bucket/prefixB,
Permission=READ
)
```

View a grant

You can view the details of an access grant in your Amazon S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view the details of an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.
6. In the **Grants** section, find the access grant that you want to view. To filter the list of grants, use the search box.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *`user input placeholders`* with your own information.

Example– Get the details of an access grant

```
aws s3control get-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:41:34.663000+00:00",
    "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant-a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "Grantee": {
        "GranteeType": "IAM",
        "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
    },
    "Permission": "READ",
    "AccessGrantsLocationId": "12a6710f-5af8-41f5-b035-0bc795bf1a2b",
    "AccessGrantsLocationConfiguration": {
        "S3SubPrefix": "prefixB*"
    },
    "GrantScope": "s3://amzn-s3-demo-bucket/"
}
```

Example– List all of the access grants in an S3 Access Grants instance

You can optionally use the following parameters to restrict the results to an S3 prefix or AWS Identity and Access Management (IAM) identity:

- **Subprefix** – `--grant-scope s3://bucket-name/prefix*`
- **IAM identity** – `--grantee-type IAM` and `--grantee-identifier arn:aws:iam::123456789000:role/accessGrantsConsumerRole`

```
aws s3control list-access-grants \
--account-id 111122223333
```

Response:

```
{
    "AccessGrantsList": [{"CreatedAt": "2023-06-14T17:54:46.542000+00:00",
            "AccessGrantId": "dd8dd089-b224-4d82-95f6-975b4185bbaa",
            "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/dd8dd089-b224-4d82-95f6-975b4185bbaa",
            "Grantee": {
                "GranteeType": "IAM",
                "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
            },
            "Permission": "READ",
            "AccessGrantsLocationId": "23514a34-ea2e-4ddf-b425-d0d4bfcarda1",
            "GrantScope": "s3://amzn-s3-demo-bucket/prefixA*"
        },
        {"CreatedAt": "2023-06-24T17:54:46.542000+00:00",
            "AccessGrantId": "ee8ee089-b224-4d72-85f6-975b4185a1b2",
            "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2",
            "Grantee": {
                "GranteeType": "IAM",
                "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-9"
            },
            "Permission": "READ",
            "AccessGrantsLocationId": "12414a34-ea2e-4ddf-b425-d0d4bfcacao0",
            "GrantScope": "s3://amzn-s3-demo-bucket/prefixB*"
        },

    ]
```

```
}
```

Using the REST API

You can use Amazon S3 API operations to view the details of an access grant and list all access grants in an S3 Access Grants instance. For information about the REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetAccessGrant
- ListAccessGrants

Using the AWS SDKs

This section provides examples of how to get the details of an access grant by using the AWS SDKs.

To use the following examples, replace the *`user input placeholders`* with your own information.

Java

Example– Get the details of an access grant

```
public void getAccessGrant() {
GetAccessGrantRequest getRequest = GetAccessGrantRequest.builder()
.accountId("111122223333")
.accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE22222")
.build();
GetAccessGrantResponse getResponse = s3Control.getAccessGrant(getRequest);
LOGGER.info("GetAccessGrantResponse: " + getResponse);
}
```

Response:

```
GetAccessGrantResponse(
CreatedAt=2023-06-07T05:20:26.330Z,
AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE22222,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant-fd3a5086-42f7-4b34-9fad-472e2942c70e,
Grantee=Grantee(
```

```
GranteeType=IAM,
GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3
),
Permission=READ,
AccessGrantsLocationId=12a6710f-5af8-41f5-b035-0bc795bf1a2b,
AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(
S3SubPrefix=prefixB*
),
GrantScope=s3://amzn-s3-demo-bucket/
)
```

Example– List all of the access grants in an S3 Access Grants instance

You can optionally use these parameters to restrict the results to an S3 prefix or IAM identity:

- **Scope** – `GrantScope=s3://bucket-name/prefix*`
- **Grantee** – `GranteeType=IAM` and `GranteeIdentifier=arn:aws:iam::111122223333:role/accessGrantsConsumerRole`

```
public void listAccessGrants() {
ListAccessGrantsRequest listRequest = ListAccessGrantsRequest.builder()
.accountId("111122223333")
.build();
ListAccessGrantsResponse listResponse = s3Control.listAccessGrants(listRequest);
LOGGER.info("ListAccessGrantsResponse: " + listResponse);
}
```

Response:

```
ListAccessGrantsResponse(
AccessGrantsList=[
ListAccessGrantEntry(
CreatedAt=2023-06-14T17:54:46.540z,
AccessGrantId=dd8dd089-b224-4d82-95f6-975b4185bbaa,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/dd8dd089-b224-4d82-95f6-975b4185bbaa,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-3
),
```

```
Permission=READ,
AccessGrantsLocationId=23514a34-ea2e-4ddf-b425-d0d4bfcarda1,
GrantScope=s3://amzn-s3-demo-bucket/prefixA
),
ListAccessGrantEntry(
CreatedAt=2023-06-24T17:54:46.540Z,
AccessGrantId=ee8ee089-b224-4d72-85f6-975b4185a1b2,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-9
),
Permission=READ,
AccessGrantsLocationId=12414a34-ea2e-4ddf-b425-d0d4bfcacao0,
GrantScope=s3://amzn-s3-demo-bucket/prefixB*
)
]
)
```

Delete a grant

You can delete access grants from your Amazon S3 Access Grants instance. You can't undo an access grant deletion. After you delete an access grant, the grantee will no longer have access to your Amazon S3 data.

You can delete an access grant by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.

6. Search for the grant that you want to delete. When you locate the grant, choose the radio button next to it.
7. Choose **Delete**. A dialog box appears with a warning that your action can't be undone. Choose **Delete** again to delete the grant.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example– Delete an access grant

```
aws s3control delete-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see DeleteAccessGrant in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to delete an access grant by using the AWS SDKs. To use the following example, replace the *`user input placeholders`* with your own information.

Java

Example– Delete an access grant

```
public void deleteAccessGrant() {
DeleteAccessGrantRequest deleteRequest = DeleteAccessGrantRequest.builder()
.accountId("111122223333")
.accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE11111")
.build();
DeleteAccessGrantResponse deleteResponse =
 s3Control.deleteAccessGrant(deleteRequest);
```

```
LOGGER.info("DeleteAccessGrantResponse: " + deleteResponse);
}
```

Response:

```
DeleteAccessGrantResponse()
```

Getting S3 data using access grants

Grantees who have been given access to S3 data through S3 Access Grants must request temporary credentials from S3 Access Grants, which they use to access the S3 data. For more information, see Request access to Amazon S3 data through S3 Access Grants. Grantees then use the temporary credentials to perform allowable S3 actions on the S3 data. For more information, see Accessing S3 data using credentials vended by S3 Access Grants. Grantees can optionally request a list of their access grants for an AWS account before requesting these credentials. For more information, see List the caller's access grants.

Topics

- Request access to Amazon S3 data through S3 Access Grants
- Accessing S3 data using credentials vended by S3 Access Grants
- List the caller's access grants

Request access to Amazon S3 data through S3 Access Grants

After you create an access grant using S3 Access Grants, grantees can request credentials to access the S3 data that they were granted access to. Grantees can be AWS Identity and Access Management (IAM) principals, your corporate directory identities, or authorized applications.

An application or AWS service can use the S3 Access Grants `GetDataAccess` API operation to ask S3 Access Grants for access to your S3 data on behalf of a grantee. `GetDataAccess` first verifies that you have granted this identity access to the data. Then, S3 Access Grants uses the AssumeRole API operation to obtain a temporary credential token and vends it to the requester. This temporary credential token is an AWS Security Token Service (AWS STS) token.

The `GetDataAccess` request must include the `target` parameter, which specifies the scope of the S3 data that the temporary credentials apply to. This `target` scope can be the same as the scope of the grant or a subset of that scope, but the `target` scope must be within the scope of the

grant that was given to the grantee. The request must also specify the `permission` parameter to indicate the permission level for the temporary credentials, whether `READ`, `WRITE`, or `READWRITE`.

Privilege

The requester can specify the privilege level of the temporary token in their credential request. Using the `privilege` parameter, the requester can reduce or increase the temporary credentials' scope of access, within the boundaries of the grant scope. The default value of the `privilege` parameter is `Default`, which means that the target scope of the credential returned is the original grant scope. The other possible value for `privilege` is `Minimal`. If the `target` scope is reduced from the original grant scope, then the temporary credential is de-scoped to match the `target` scope, as long as the `target` scope is within the grant scope.

The following table details the effect of the `privilege` parameter on two grants. One grant has the scope `S3://amzn-s3-demo-bucket1/bob/*`, which includes the entire bob/ prefix in the *amzn-s3-demo-bucket1* bucket. The other grant has the scope `S3://amzn-s3-demo-bucket1/bob/reports/*`, which includes only the bob/reports/ prefix in the *amzn-s3-demo-bucket1* bucket.

Grant scope	Requested scope	Privilege	Returned scope	Effect
S3://*amzn-s3-demo-bucket1* /bob/*	*amzn-s3-demo-bucket1* /bob/*	Default	*amzn-s3-demo-bucket1* /bob/*	The requester has access to all objects that have key names that start with the prefix *bob/* in the *amzn-s3-demo-bucket1* bucket.
S3://*amzn-s3-demo-bucket1* /bob/*	*amzn-s3-demo-bucket1* /bob/	Minimal	*amzn-s3-demo-bucket1* /bob/	Without a wild card * character after the prefix name bob/, the requester has access to only the object named bob/ in the *amzn-s3-demo-bucket1* bucket. It's not common to have such an object.

Grant scope	Requested scope	Privilege	Returned scope	Effect
				The requester doesn't have access to any other objects, including those that have key names that start with the bob/ prefix.
S3://*amzn-s3-demo-bucket1* /bob/*	*amzn-s3-demo-bucket1* /bob/images/*	Minimal	*amzn-s3-demo-bucket1* /bob/images/*	The requester has access to all objects that have key names that start with the prefix *bob/images/** in the *amzn-s3-demo-bucket1* bucket.
S3://*amzn-s3-demo-bucket1* /bob/reports/*	*amzn-s3-demo-bucket1* /bob/reports/file.txt	Default	*amzn-s3-demo-bucket1* /bob/reports/*	The requester has access to all objects that have key names that start with the bob/reports prefix in the *amzn-s3-demo-bucket1* bucket, which is the scope of the matching grant.
S3://*amzn-s3-demo-bucket1* /bob/reports/*	*amzn-s3-demo-bucket1* /bob/reports/file.txt	Minimal	*amzn-s3-demo-bucket1* /bob/reports/file.txt	The requester has access only to the object with the key name bob/reports/file.txt in the *amzn-s3-demo-bucket1* bucket. The requester has no access to any other object.

Directory identities

`GetDataAccess` considers all of the identities involved in a request when matching suitable grants. For corporate directory identities, `GetDataAccess` also returns the grants of the IAM identity that is used for the identity-aware session. For more information on identity-aware sessions, see Granting permissions to use identity-aware console sessions in the *AWS Identity and Access Management User Guide*. `GetDataAccess` generates credentials restricting scope to the most restrictive grant, as shown in the following table:

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
S3://*amzn-s3-demo-bucket1* / bob/*	*amzn-s3-demo-bucket1* / bob/images/*	S3://*amzn-s3-demo-bucket1* / bob/images/image1.jpeg	S3://*amzn-s3-demo-bucket1* / bob/images/*	Default	The requestor has access to all of the objects that have key names that start with the prefix *bob/* as a part of the grant for the IAM role but is restricted to the prefixes *bob/images/* as a part of the grant for the directory identity. Both the IAM role and directory identity provide access to the requested scope, which is bob/images/image1.jpeg , but the directory identity has a more restrictive grant. So, the returned scope is restricted to the more

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
					restrictive grant for the directory identity.
S3://amzn-s3-demo-bucket1 / bob/*	amzn-s3-demo-bucket1 / bob/images/*	S3://amzn-s3-demo-bucket1 / bob/images/image1.jpeg	S3://amzn-s3-demo-bucket1 / bob/images/image1.jpeg	Minimal	Because the Privilege is set to Minimal, even though the identity has access to a bigger scope, only the requested scope is returned bob/images/image1.jpeg .

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
S3://*amzn-s3-demo-bucket1* / bob/images/*	*amzn-s3-demo-bucket1* / bob/*	S3://*amzn-s3-demo-bucket1* / bob/images/image1.jpeg	S3://*amzn-s3-demo-bucket1* / bob/images/*	Default	The requestor has access to all of the objects that have key names that start with the prefix *bob/* as a part of the grant for the directory identity but is restricted to the prefixes *bob/images/* as a part of the grant for the IAM role. Both the IAM role and directory identity provide access to the requested scope, which is bob/images/image1.jpeg , but the IAM role has a more restrictive grant. So, the returned scope is restricted to the more restrictive grant for the IAM role.

Grant scope for IAM identity	Grant scope for directory identity	Requested scope	Returned scope	Privilege	Effect
S3://*amzn-s3-demo-bucket1* / bob/images/*	*amzn-s3-demo-bucket1* / bob/*	S3://*amzn-s3-demo-bucket1* / bob/images/image1.jpeg	S3://*amzn-s3-demo-bucket1* / bob/images/image1.jpeg	Minimal	Because the Privilege is set to Minimal, even though the identity has access to a bigger scope, only the requested scope is returned bob/images/image1.jpeg .

Duration

The durationSeconds parameter sets the temporary credential's duration, in seconds. The default value is 3600 seconds (1 hour), but the requester (the grantee) can specify a range from 900 seconds (15 minutes) up to 43200 seconds (12 hours). If the grantee requests a value higher than this maximum, the request fails.

Instance scope

The instanceScope parameter sets the scope of S3 Access Grants instances that S3 Access Grants searches for a grant that matches the target parameter. The default value is SELF, but the requester can set instanceScope to ALL. With SELF, the AWS account ID you pass in the request must be the account that owns the data, and S3 Access Grants returns credentials for the matching grant in that account's instance. If instances from other accounts are shared with you through AWS Resource Access Manager (AWS RAM), you can set instanceScope to ALL. S3 Access Grants then finds the account that owns the bucket in target and returns credentials for the matching grant in that account's instance. With ALL, the account ID in the request can be your own account ID. In both cases, the response includes the MatchedInstanceArn field, which identifies the instance that contains the matching grant. With SELF, this is the instance of the account ID in the request. With ALL, it's the instance where the grant matched, which can belong to another account.

> **Note**
>
> In your request for a temporary token, if the location is an object, set the value of the `targetType` parameter in your request to `Object`. This parameter is required only if the location is an object and the privilege level is `Minimal`. If the location is a bucket or a prefix, you don't need to specify this parameter.

Examples

You can request temporary credentials by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs. See these examples.

For additional information, see GetDataAccess in the *Amazon Simple Storage Service API Reference*.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example Request temporary credentials

Request:

```
aws s3control get-data-access \
--account-id 111122223333 \
--target s3://amzn-s3-demo-bucket/prefixA* \
--permission READ \
--privilege Default \
--region us-east-2
```

Response:

```
{
"Credentials": {
"AccessKeyId": "Example-key-id",
"SecretAccessKey": "Example-access-key",
"SessionToken": "Example-session-token",
"Expiration": "2023-06-14T18:56:45+00:00"},
"MatchedGrantTarget": "s3://amzn-s3-demo-bucket/prefixA**",
```

```
"Grantee": {
    "GranteeType": "IAM",
    "GranteeIdentifier": "arn:aws:iam::111122223333:role/role-name"
 }
}
```

Using the REST API

For information about the Amazon S3 REST API support for requesting temporary credentials from S3 Access Grants, see GetDataAccess in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the temporary credentials that the grantee uses to access your S3 data. To use this code example, replace the *`user input placeholders`* with your own information.

Example Get temporary credentials

Request:

```
public void getDataAccess() {
GetDataAccessRequest getDataAccessRequest = GetDataAccessRequest.builder()
.accountId("111122223333")
.permission(Permission.READ)
.privilege(Privilege.MINIMAL)
.target("s3://amzn-s3-demo-bucket/prefixA*")
.build();
GetDataAccessResponse getDataAccessResponse =
 s3Control.getDataAccess(getDataAccessRequest);
LOGGER.info("GetDataAccessResponse: " + getDataAccessResponse);
}
```

Response:

```
GetDataAccessResponse(
Credentials=Credentials(
AccessKeyId="Example-access-key-id",
```

```
SecretAccessKey="Example-secret-access-key",
SessionToken="Example-session-token",
Expiration=2023-06-07T06:55:24Z
))
```

Accessing S3 data using credentials vended by S3 Access Grants

After a grantee obtains temporary credentials through their access grant, they can use these temporary credentials to call Amazon S3 API operations to access your data.

Grantees can access S3 data by using the AWS Command Line Interface (AWS CLI), the AWS SDKs, and the Amazon S3 REST API. Additionally, you can use the AWS Python and Java plugins to call S3 Access Grants

Using the AWS CLI

After the grantee obtains their temporary credentials from S3 Access Grants, they can set up a profile with these credentials to retrieve the data.

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *user input placeholders* with your own information.

Example– Set up a profile

```
aws configure set aws_access_key_id "$accessKey" --profile access-grants-consumer-access-profile
aws configure set aws_secret_access_key "$secretKey" --profile access-grants-consumer-access-profile
aws configure set aws_session_token "$sessionToken" --profile access-grants-consumer-access-profile
```

To use the following example command, replace the *user input placeholders* with your own information.

Example– Get the S3 data

The grantee can use the get-object AWS CLI command to access the data. The grantee can also use put-object, ls, and other S3 AWS CLI commands.

```
aws s3api get-object \
```

```
--bucket amzn-s3-demo-bucket1 \
--key myprefix \
--region us-east-2 \
--profile access-grants-consumer-access-profile
```

Using the AWS SDKs

This section provides examples of how grantees can access your S3 data by using the AWS SDKs.

Java

The following Java code example gets an object from an S3 bucket. For instructions on creating and testing a working sample, see Getting Started in the *AWS SDK for Java Developer Guide*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.GetObjectRequest;
import com.amazonaws.services.s3.model.ResponseHeaderOverrides;
import com.amazonaws.services.s3.model.S3Object;

import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;

public class GetObject2 {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String key = "*** Object key ***";

        S3Object fullObject = null, objectPortion = null, headerOverrideObject =
 null;
        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();
```

```
            // Get an object and print its contents.
            System.out.println("Downloading an object");
            fullObject = s3Client.getObject(new GetObjectRequest(bucketName, key));
            System.out.println("Content-Type: " +
fullObject.getObjectMetadata().getContentType());
            System.out.println("Content: ");
            displayTextInputStream(fullObject.getObjectContent());

            // Get a range of bytes from an object and print the bytes.
            GetObjectRequest rangeObjectRequest = new GetObjectRequest(bucketName,
key)
                    .withRange(0, 9);
            objectPortion = s3Client.getObject(rangeObjectRequest);
            System.out.println("Printing bytes retrieved.");
            displayTextInputStream(objectPortion.getObjectContent());

            // Get an entire object, overriding the specified response headers, and
print
            // the object's content.
            ResponseHeaderOverrides headerOverrides = new ResponseHeaderOverrides()
                    .withCacheControl("No-cache")
                    .withContentDisposition("attachment; filename=example.txt");
            GetObjectRequest getObjectRequestHeaderOverride = new
GetObjectRequest(bucketName, key)
                    .withResponseHeaders(headerOverrides);
            headerOverrideObject =
s3Client.getObject(getObjectRequestHeaderOverride);
            displayTextInputStream(headerOverrideObject.getObjectContent());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        } finally {
            // To ensure that the network connection doesn't remain open, close any
open
            // input streams.
            if (fullObject != null) {
                fullObject.close();
            }
```

```
            if (objectPortion != null) {
                objectPortion.close();
            }
            if (headerOverrideObject != null) {
                headerOverrideObject.close();
            }
        }
    }

    private static void displayTextInputStream(InputStream input) throws IOException
 {
        // Read the text input stream one line at a time and display each line.
        BufferedReader reader = new BufferedReader(new InputStreamReader(input));
        String line = null;
        while ((line = reader.readLine()) != null) {
            System.out.println(line);
        }
        System.out.println();
    }
}
```

Supported S3 actions in S3 Access Grants

A grantee can use the temporary credential vended by S3 Access Grants to perform S3 actions on the S3 data they have access to. The following is a list of allowable S3 actions that a grantee can perform. Which actions are allowable depends on the level of permission granted in the access grant, either `READ`, `WRITE`, or `READWRITE`.

> **Note**
>
> In addition to the Amazon S3 permissions listed below, Amazon S3 can call the AWS Key Management Service (AWS KMS) Decrypt (`kms:decrypt`) `READ` permission or the AWS KMS GenerateDataKey (`kms:generateDataKey`) `WRITE` permission. These permissions don't allow direct access to the AWS KMS key.

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:GetObject	GetObject	READ	Object			
s3:GetObjectVersion	GetObject	READ	Object			
s3:GetObjectAcl	GetObjectAcl	READ	Object			
s3:GetObjectVersionAcl	GetObjectAcl	READ	Object			
s3:ListMultipartUploads	ListParts	READ	Object			
s3:PutObject	PutObject, CreateMultipartUpload, UploadPart, UploadPartCopy, CompleteMultipartUpload	WRITE	Object			
s3:PutObjectAcl	PutObjectAcl	WRITE	Object			
s3:PutObjectVersionAcl	PutObjectAcl	WRITE	Object			
s3:DeleteObject	DeleteObject	WRITE	Object			

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:DeleteObjectVersion	DeleteObject	WRITE	Object			
s3:AbortMultipartUpload	AbortMultipartUpload	WRITE	Object			
s3:ListBucket	HeadBucket, ListObjectsV2, ListObjects	READ	Bucket			
s3:ListBucketVersions	ListObjectVersions	READ	Bucket			
s3:ListBucketMultipartUploads	ListMultipartUploads	READ	Bucket			

List the caller's access grants

S3 data owners can use S3 Access Grants to create access grants for AWS Identity and Access Management (IAM) identities or for AWS IAM Identity Center corporate directory identities. IAM identies and IAM Identity Center directory identities can in turn use the `ListCallerAccessGrants` API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or directory identity can access through S3 Access Grants.

By default, `ListCallerAccessGrants` returns grants from the S3 Access Grants instance in the AWS account ID you provide. To list grants across your own instance and every instance shared with you through AWS Resource Access Manager (AWS RAM), set the `instanceScope` parameter to

ALL. Each returned grant includes the `AccessGrantsInstanceArn` of the instance it belongs to, so you can tell which account owns it.

You can use this feature to build applications that show the data that is accessible to specific end-users. For example, the AWS Storage Browser for S3, an open source UI component that customers use to access S3 buckets, uses this feature to present end-users with the data that they have access to in Amazon S3, based on their S3 Access Grants. Another example is when building an application for browsing, uploading, or downloading data in Amazon S3, you can use this feature to build a tree structure in your application that an end-user could then browse.

> **Note**
>
> For corporate directory identities, when listing the caller's access grants, S3 Access Grants returns the grants of the IAM identity that is used for the identity-aware session. For more information on identity-aware sessions, see Granting permissions to use identity-aware console sessions in the *AWS Identity and Access Management User Guide*.

The grantee whether an IAM identity, or a corporate directory identity can get a list of their access grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *`user input placeholders`* with your own information.

Example List a caller's access grants

Request:

```
aws s3control list-caller-access-grants \
--account-id 111122223333 \
--region us-east-2
--max-results 5
```

Response:

```
{
 "NextToken": "6J9S...",
 "CallerAccessGrantsList": [
  {
   "Permission": "READWRITE",
   "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix1/*",
   "ApplicationArn": "NA"
  },
  {
   "Permission": "READWRITE",
   "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix2/*",
   "ApplicationArn": "ALL"
  },
  {
   "Permission": "READWRITE",
   "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix3/*",
   "ApplicationArn": "arn:aws:sso::111122223333:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
  }
 ]
}
```

Example List a caller's access grants for a bucket

You can narrow the scope of the results using the `grantscope` parameter.

Request:

```
aws s3control list-caller-access-grants \
--account-id 111122223333 \
--region us-east-2
--grant-scope "s3://amzn-s3-demo-bucket""
--max-results 1000
```

Response:

```
{
 "NextToken": "6J9S...",
 "CallerAccessGrantsList": [
  {
   "Permission": "READ",
   "GrantScope": "s3://amzn-s3-demo-bucket*",
```

```
    "ApplicationArn": "ALL"
   },
   {
    "Permission": "READ",
    "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/*",
    "ApplicationArn": "arn:aws:sso::111122223333:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
   }
 ]
}
```

Example List a caller's access grants across all shared instances

You can list all the grants you have access to across the instances shared with you by setting the `instanceScope` parameter to `ALL`.

Request:

```
aws s3control list-caller-access-grants \
--account-id 111122223333 \
--instance-scope ALL \
--region us-east-2 \
--max-results 5
```

Response (grants returned from two different accounts' instances):

```
{
 "CallerAccessGrantsList": [
  {
   "Permission": "READWRITE",
   "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/*",
   "ApplicationArn": "NA",
   "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
  },
  {
   "Permission": "READ",
   "GrantScope": "s3://amzn-s3-demo-other-bucket/reports/*",
   "ApplicationArn": "NA",
   "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:444455556666:access-grants/default"
  }
 ]
}
```

Using the REST API

For information about the Amazon S3 REST API support for getting a list of the API caller's access grants, see ListCallerAccessGrants in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the API caller's access grants to the S3 data of a particular AWS account. To use this code example, replace the *`user input placeholders`* with your own information.

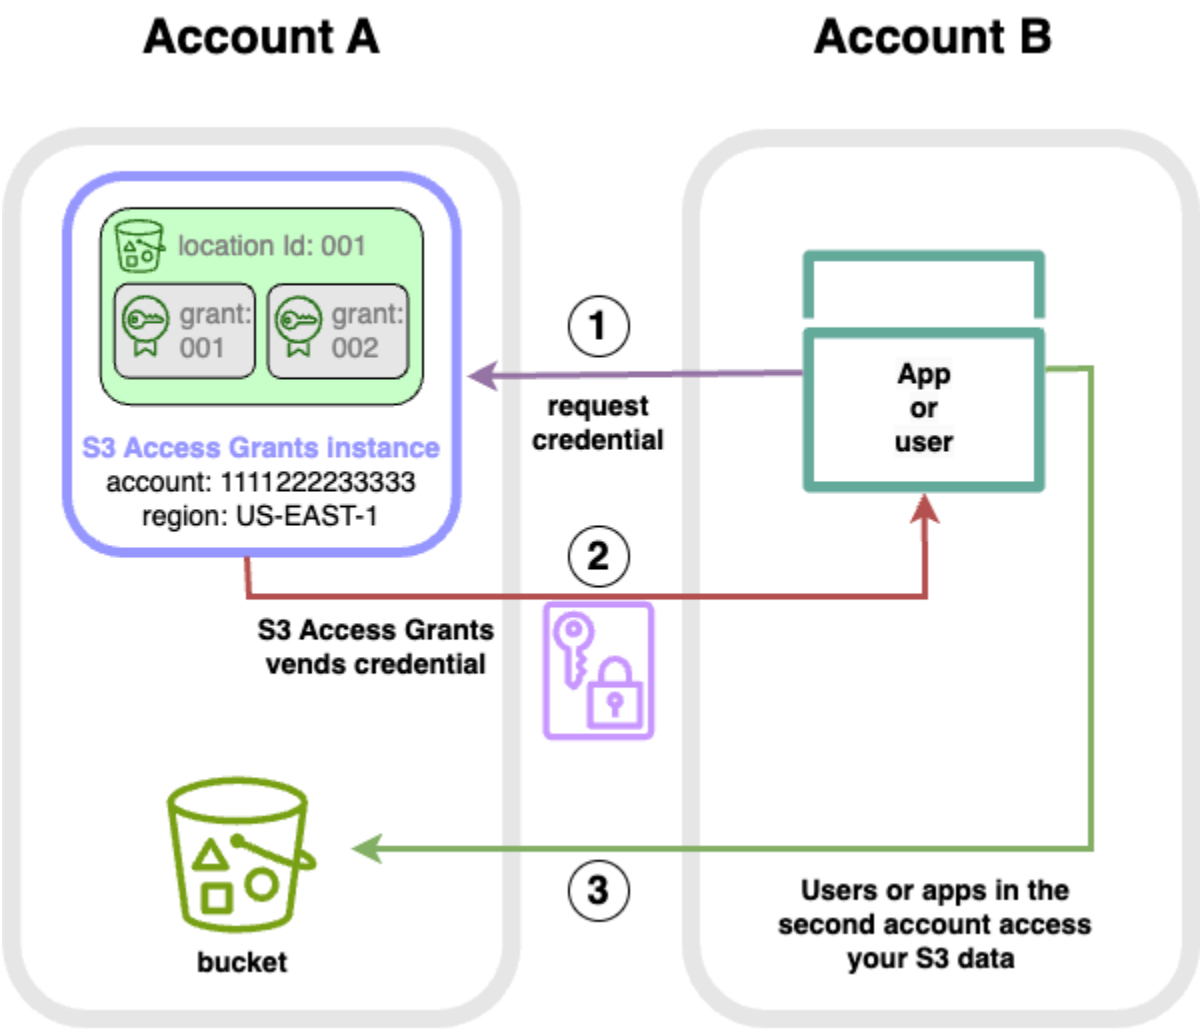
Example List a caller's access grants

Request:

```
Public void ListCallerAccessGrants() {
 ListCallerAccessGrantsRequest listRequest = ListCallerAccessGrantsRequest.builder()
    .withMaxResults(1000)
    .withGrantScope("s3://")
    .accountId("111122223333");
 ListCallerAccessGrantsResponse listResponse =
 s3control.listCallerAccessGrants(listRequest);
 LOGGER.info("ListCallerAccessGrantsResponse: " + listResponse);
 }
```

Response:

```
ListCallerAccessGrantsResponse(
CallerAccessGrantsList=[
 ListCallerAccessGrantsEntry(
  S3Prefix=s3://amzn-s3-demo-bucket/prefix1/,
  Permission=READ,
  ApplicationArn=ALL
 )
])
```



S3 Access Grants cross-account access

With S3 Access Grants, you can grant Amazon S3 data access to the following:

- AWS Identity and Access Management (IAM) identities within your account
- IAM identities in other AWS accounts
- Directory users or groups in your AWS IAM Identity Center instance

First, configure cross-account access for the other account. This includes granting access to your S3 Access Grants instance, either by sharing it through AWS Resource Access Manager (AWS RAM) or by using a resource policy. Then, grant access to your S3 data (buckets, prefixes, or objects) by using grants.

After you configure cross-account access, the other account can request temporary access credentials to your Amazon S3 data from S3 Access Grants. The following image shows the user flow for cross-account S3 access through S3 Access Grants:

1. Users or applications in a second account (B) request credentials from the S3 Access Grants instance in your account (A), where the Amazon S3 data is stored. For more information, see Request access to Amazon S3 data through S3 Access Grants.
2. The S3 Access Grants instance in your account (A) returns temporary credentials if there is a grant that gives the second account access to your Amazon S3 data. For more information on access grants, see Working with grants in S3 Access Grants.
3. Users or applications in the second account (B) use the S3 Access Grants-vended credentials to access the S3 data in your account (A).

Configuring S3 Access Grants cross-account access

To grant cross-account S3 access through S3 Access Grants, follow these steps:

- **Step 1:** Configure an S3 Access Grants instance in your account, for example, account ID 111122223333, where the S3 data is stored.
- **Step 2:** Configure the resource policy for the S3 Access Grants instance in your account 111122223333 to give access to the second account, for example, account ID 444455556666.
- **Step 3:** Configure the IAM permissions for the IAM Principal in the second account 444455556666 to request credentials from the S3 Access Grants instance in your account 111122223333.
- **Step 4:** Create a grant in your account 111122223333 that gives the IAM Principal in the second account 444455556666 access to some of the S3 data in your account 111122223333.

Step 1: Configure an S3 Access Grants instance in your account

First, you must have an S3 Access Grants instance in your account 111122223333 to manage access to your Amazon S3 data. You must create an S3 Access Grants instance in each AWS Region where the S3 data that you want to share is stored. If you are sharing data in more than one AWS Region, then repeat each of these configuration steps for each AWS Region. If you already have an S3 Access Grants instance in the AWS Region where your S3 data is stored, proceed to the next step. If you haven't configured an S3 Access Grants instance, see Working with S3 Access Grants instances to complete this step.

Step 2: Configure the resource policy for your S3 Access Grants instance to grant cross-account access

After you create an S3 Access Grants instance in your account 111122223333 for cross-account access, configure the resource-based policy for the S3 Access Grants instance in your account 111122223333 to grant cross-account access. The S3 Access Grants instance itself supports resource-based policies. With the correct resource-based policy in place, you can grant access for AWS Identity and Access Management (IAM) users or roles from other AWS accounts to your S3 Access Grants instance. Cross-account access only grants these permissions (actions):

- `s3:GetAccessGrantsInstanceForPrefix` — the user, role, or app can retrieve the S3 Access Grants instance that contains a particular prefix.
- `s3:ListAccessGrants`
- `s3:ListAccessLocations`
- `s3:ListCallerAccessGrants`

- `s3:GetDataAccess` — the user, role, or app can request temporary credentials based on the access you were granted through S3 Access Grants. Use these credentials to access the S3 data to which you have been granted access.

You can choose which of these permissions to include in the resource policy. This resource policy on the S3 Access Grants instance is a normal resource-based policy and supports everything that the IAM policy language supports. In the same policy, you can grant access to specific IAM identities in your account `111122223333`, for example, by using the `aws:PrincipalArn` condition, but you don't have to do that with S3 Access Grants. Instead, within your S3 Access Grants instance, you can create grants for individual IAM identities from your account, as well as for the other account. By managing each access grant through S3 Access Grants, you can scale your permissions.

If you already use AWS Resource Access Manager (AWS RAM), you can use it to share your `s3:AccessGrants` resources with other accounts or within your organization. See Working with shared AWS resources for more information. If you don't use AWS RAM, you can also add the resource policy by using the S3 Access Grants API operations or the AWS Command Line Interface (AWS CLI).

Using the S3 console

We recommend that you use the AWS Resource Access Manager (AWS RAM) Console to share your `s3:AccessGrants` resources with other accounts or within your organization. To share S3 Access Grants cross-account, do the following:

To configure the S3 Access Grants instance resource policy:

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Select the AWS Region from the AWS Region selector.
3. From the left navigation pane, select **Access Grants**.
4. On the Access Grants instance page, in the **Instance in this account** section, select **Share instance**. This will redirect you to the AWS RAM Console.
5. Select **Create resource share**.
6. Follow the AWS RAM steps to create the resource share. For more information, see Creating a resource share in AWS RAM.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

You can add the resource policy by using the `put-access-grants-instance-resource-policy` CLI command.

If you want to grant cross-account access for the S3 Access Grants instance is in your account `111122223333` to the second account `444455556666`, the resource policy for the S3 Access Grants instance in your account `111122223333` should give the second account `444455556666` permission to perform the following actions:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the `Resource`, and the second account `444455556666` as the `Principal`. To use the following example, replace the *`user input placeholders`* with your own information.

```
{
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
},
 "Action": [
  "s3:ListAccessGrants",
  "s3:ListAccessGrantsLocations",
  "s3:GetDataAccess",
  "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
} ]
}
```

To add or update the S3 Access Grants instance resource policy, use the following command. When you use the following example command, replace the *user input placeholders* with your own information.

Example Add or update the S3 Access Grants instance resource policy

```
aws s3control put-access-grants-instance-resource-policy \
--account-id 111122223333 \
--policy file://resourcePolicy.json \
--region us-east-2
{
 "Policy": "{\n
   \"Version\": \"2012-10-17\",\n
   \"Statement\": [{\n
  \"Effect\": \"Allow\",\n
  \"Principal\": {\n
    \"AWS\": \"444455556666\"\n
  },\n
  \"Action\": [\n
    \"s3:ListAccessGrants\",\n
    \"s3:ListAccessGrantsLocations\",\n
    \"s3:GetDataAccess\",\n
    \"s3:GetAccessGrantsInstanceForPrefix\",\n
    \"s3:ListCallerAccessGrants"\n
  ],\n
  \"Resource\": \"arn:aws:s3:us-east-2:111122223333:access-grants/default\"\n
    }\n
   ]\n
   }\n",
 "CreatedAt": "2023-06-16T00:07:47.473000+00:00"
}
```

Example Get an S3 Access Grants resource policy

You can also use the CLI to get or delete a resource policy for an S3 Access Grants instance.

To get an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-access-grants-instance-resource-policy \
--account-id 111122223333 \
--region us-east-2
```

```
{
"Policy": "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":\"Allow
\",\"Principal\":{\"AWS\":\"arn:aws:iam::111122223333:root\"},\"Action\":
[\"s3:ListAccessGrants\",\"s3:ListAccessGrantsLocations\",\"s3:GetDataAccess\",
\"s3:GetAccessGrantsInstanceForPrefix\",\"s3:ListCallerAccessGrants\"],\"Resource\":
\"arn:aws:
s3:us-east-2:111122223333:access-grants/default\"}]}",
"CreatedAt": "2023-06-16T00:07:47.473000+00:00"
}
```

Example Delete an S3 Access Grants resource policy

To delete an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-access-grants-instance-resource-policy \
--account-id 111122223333 \
--region us-east-2

// No response body
```

Using the REST API

You can add the resource policy by using the PutAccessGrantsInstanceResourcePolicy API.

If you want to grant cross-account access for the S3 Access Grants instance is in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the `Resource`, and the second account 444455556666 as the `Principal`. To use the following example, replace the *user input placeholders* with your own information.

```
{
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
},
 "Action": [
  "s3:ListAccessGrants",
  "s3:ListAccessGrantsLocations",
  "s3:GetDataAccess",
  "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
} ]
}
```

You can then use the PutAccessGrantsInstanceResourcePolicy API to configure the policy.

For information on the REST API support to update, get, or delete a resource policy for an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- PutAccessGrantsInstanceResourcePolicy
- GetAccessGrantsInstanceResourcePolicy
- DeleteAccessGrantsInstanceResourcePolicy

Using the AWS SDKs

This section provides you with the AWS SDK examples of how to configure your S3 Access Grants resource policy to grant a second AWS account access to some of your S3 data.

Java

Add, update, get, or delete a resource policy to manage cross-account access to your S3 Access Grants instance.

Example Add or update an S3 Access Grants instance resource policy

If you want to grant cross-account access for the S3 Access Grants instance is in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the `Resource`, and the second account 444455556666 as the `Principal`. To use the following example, replace the *`user input placeholders`* with your own information.

```
{
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
},
 "Action": [
  "s3:ListAccessGrants",
  "s3:ListAccessGrantsLocations",
  "s3:GetDataAccess",
  "s3:GetAccessGrantsInstanceForPrefix"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
} ]
}
```

To add or update an S3 Access Grants instance resource policy, use the following code example:

```
public void putAccessGrantsInstanceResourcePolicy() {
 PutAccessGrantsInstanceResourcePolicyRequest putRequest =
 PutAccessGrantsInstanceResourcePolicyRequest.builder()
 .accountId(111122223333)
```

```
 .policy(RESOURCE_POLICY)
 .build();
 PutAccessGrantsInstanceResourcePolicyResponse putResponse =
 s3Control.putAccessGrantsInstanceResourcePolicy(putRequest);
 LOGGER.info("PutAccessGrantsInstanceResourcePolicyResponse: " + putResponse);
 }
```

Response:

```
PutAccessGrantsInstanceResourcePolicyResponse(
 Policy={
 "Version": "2012-10-17",
 "Statement": [{
 "Effect": "Allow",
 "Principal": {
 "AWS": "444455556666"
 },
 "Action": [
 "s3:ListAccessGrants",
 "s3:ListAccessGrantsLocations",
 "s3:GetDataAccess",
 "s3:GetAccessGrantsInstanceForPrefix",
 "s3:ListCallerAccessGrants"
 ],
 "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
 }]
 }
 )
```

Example Get an S3 Access Grants resource policy

To get an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *`user input placeholders`* with your own information.

```
public void getAccessGrantsInstanceResourcePolicy() {
 GetAccessGrantsInstanceResourcePolicyRequest getRequest =
 GetAccessGrantsInstanceResourcePolicyRequest.builder()
 .accountId(111122223333)
 .build();
 GetAccessGrantsInstanceResourcePolicyResponse getResponse =
 s3Control.getAccessGrantsInstanceResourcePolicy(getRequest);
```

```
 LOGGER.info("GetAccessGrantsInstanceResourcePolicyResponse: " + getResponse);
 }
```

Response:

```
GetAccessGrantsInstanceResourcePolicyResponse(
 Policy={"Version": "2012-10-17",       "Statement":
[{"Effect":"Allow","Principal":{"AWS":"arn:aws:iam::444455556666:root"},"Action":
["s3:ListAccessGrants","s3:ListAccessGrantsLocations","s3:GetDataAccess","s3:GetAccessGrants
east-2:111122223333:access-grants/default"}]},
 CreatedAt=2023-06-15T22:54:44.319Z
 )
```

Example Delete an S3 Access Grants resource policy

To delete an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void deleteAccessGrantsInstanceResourcePolicy() {
 DeleteAccessGrantsInstanceResourcePolicyRequest deleteRequest =
 DeleteAccessGrantsInstanceResourcePolicyRequest.builder()
 .accountId(111122223333)
 .build();
 DeleteAccessGrantsInstanceResourcePolicyResponse deleteResponse =
 s3Control.putAccessGrantsInstanceResourcePolicy(deleteRequest);
 LOGGER.info("DeleteAccessGrantsInstanceResourcePolicyResponse: " + deleteResponse);
 }
```

Response:

```
DeleteAccessGrantsInstanceResourcePolicyResponse()
```

Step 3: Grant IAM identities in a second account permission to call the S3 Access Grants instance in your account

After the owner of the Amazon S3 data has configured the cross-account policy for the S3 Access Grants instance in account 111122223333, the owner of the second account 444455556666 must create an identity-based policy for its IAM users or roles, and the owner must give them access to

the S3 Access Grants instance. In the identity-based policy, include one or more of the following actions, depending on what's granted in the S3 Access Grants instance resource policy and the permissions you want to grant:

- `s3:ListAccessGrants`
- `s3:ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`
- `s3:ListCallerAccessGrants`

Following the AWS cross-account access pattern, the IAM users or roles in the second account 444455556666 must explicitly have one or more of these permissions. For example, grant the `s3:GetDataAccess` permission so that the IAM user or role can call the S3 Access Grants instance in account 111122223333 to request credentials.

To use this example command, replace the *`user input placeholders`* with your own information.

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
  "Effect": "Allow",
  "Action": [
   "s3:GetDataAccess"
  ],
   "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
  }
 ]
}
```

For information on editing IAM identity-based policy, see Editing IAM policies in the *AWS Identity and Access Management guide*.

Step 4: Create a grant in the S3 Access Grants instance of your account that gives the IAM identity in the second account access to some of your S3 data

For the final configuration step, you can create a grant in the S3 Access Grants instance in your account 111122223333 that gives access to the IAM identity in the second account 444455556666

to some of the S3 data in your account. You can do this by using the Amazon S3 Console, CLI, API, and SDKs. For more information, see Create grants.

In the grant, specify the AWS ARN of the IAM identity from the second account, and specify which location in your S3 data (a bucket, prefix, or object) that you are granting access to. This location must already be registered with your S3 Access Grants instance. For more information, see Register a location. You can optionally specify a subprefix. For example, if the location you are granting access to is a bucket, and you want to limit the access further to a specific object in that bucket, then pass the object key name in the `S3SubPrefix` field. Or if you want to limit access to the objects in the bucket with key names that start with a specific prefix, such as `2024-03-research-results/`, then pass `S3SubPrefix=2024-03-research-results/`.

The following is an example CLI command for creating an access grant for an identity in the second account. See Create grants for more information. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control create-access-grant \
--account-id 111122223333 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix=prefixA* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::444455556666:role/data-consumer-1
```

After configuring cross-account access, the user or role in the second account can do the following:

- Calls `ListAccessGrantsInstances` to list the S3 Access Grants instances shared with it through AWS RAM. For more information, see Get the details of an S3 Access Grants instance.
- Calls `ListCallerAccessGrants` with `instanceScope` set to `ALL` to list the grants it has access to across its own instance and all instances shared with it through AWS RAM. For more information, see List the caller's access grants.
- Requests temporary credentials from S3 Access Grants. With `instanceScope` set to `ALL` on `GetDataAccess`, it can request credentials for a path in any instance shared with it. The account ID in the request no longer needs to be the account that owns the data. For more information on how to make these requests, see Request access to Amazon S3 data through S3 Access Grants.

Managing tags for S3 Access Grants

Tags in Amazon S3 Access Grants have similar characteristics to object tags in Amazon S3. Each tag is a key-value pair. The resources in S3 Access Grants that you can tag are S3 Access Grants instances, locations, and grants.

> **Note**
>
> Tagging in S3 Access Grants uses different API operations than object tagging. S3 Access Grants uses the TagResource, UntagResource, and ListTagsForResource API operations, where a resource can be either an S3 Access Grants instance, a registered location, or an access grant.

Similar to object tags, the following limitations apply:

- You can add tags to new S3 Access Grants resources when you create them, or you can add tags to existing resources.
- You can associate up to 10 tags with a resource. If multiple tags are associated with the same resource, they must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Tags are internally represented in UTF-16. In UTF-16, characters consume either 1 or 2 character positions.
- The keys and values are case sensitive.

For more information about tag restrictions, see User-defined tag restrictions in the *AWS Billing User Guide*.

You can tag resources in S3 Access Grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

You can tag an S3 Access Grants resource when you create it or after you have created it. The following examples show how you tag or untag an S3 Access Grants instance. You can perform similar operations for registered locations and access grants.

To use the following example commands, replace the *user input placeholders* with your own information.

Example– Create an S3 Access Grants instance with tags

```
aws s3control create-access-grants-instance \
 --account-id 111122223333 \
 --profile access-grants-profile \
 --region us-east-2 \
 --tags Key=tagKey1,Value=tagValue1
```

Response:

```
 {
    "CreatedAt": "2023-10-25T01:09:46.719000+00:00",
    "AccessGrantsInstanceId": "default",
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
default"
}
```

Example– Tag an already created S3 Access Grants instance

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2 \
--tags Key=tagKey2,Value=tagValue2
```

Example– List tags for the S3 Access Grants instance

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2
```

Response:

```
{
```

```
    "Tags": [
        {
            "Key": "tagKey1",
            "Value": "tagValue1"
        },
        {
            "Key": "tagKey2",
            "Value": "tagValue2"
        }
    ]
}
```

Example– Untag the S3 Access Grants instance

```
aws s3control untag-resource \
 --account-id 111122223333 \
 --resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
 --profile access-grants-profile \
 --region us-east-2 \
 --tag-keys "tagKey2"
```

Using the REST API

You can use the Amazon S3 API to tag, untag, or list tags for an S3 Access Grants instance, registered location, or access grant. For information about the REST API support for managing S3 Access Grants tags, see the following sections in the *Amazon Simple Storage Service API Reference*:

- TagResource
- UntagResource
- ListTagsForResource

S3 Access Grants limitations

S3 Access Grants has the following limitations:

> **Note**
>
> If your use case exceeds these limitations, contact AWS support to request higher limits.

S3 Access Grants instance

You can create **1 S3 Access Grants instance** per AWS Region per account. See Create an S3 Access Grants instance.

S3 Access Grants location

You can register **1,000 S3 Access Grants locations** per S3 Access Grants instance. See Working with S3 Access Grants locations.

Grant

You can create **100,000 grants** per S3 Access Grants instance. See Create a grant.

S3 Access Grants AWS Regions

S3 Access Grants is currently available in the following AWS Regions:

AWS Region code	AWS Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
af-south-1	Africa (Cape Town)
ap-east-1	Asia Pacific (Hong Kong)
ap-east-2	Asia Pacific (Taipei)
ap-northeast-1	Asia Pacific (Tokyo)
ap-northeast-2	Asia Pacific (Seoul)
ap-northeast-3	Asia Pacific (Osaka)
ap-south-1	Asia Pacific (Mumbai)

AWS Region code	AWS Region name
ap-south-2	Asia Pacific (Hyderabad)
ap-southeast-1	Asia Pacific (Singapore)
ap-southeast-2	Asia Pacific (Sydney)
ap-southeast-3	Asia Pacific (Jakarta)
ap-southeast-4	Asia Pacific (Melbourne)
ap-southeast-6	Asia Pacific (New Zealand)
ap-southeast-7	Asia Pacific (Thailand)
ca-central-1	Canada (Central)
ca-west-1	Canada West (Calgary)
eu-central-1	Europe (Frankfurt)
eu-central-2	Europe (Zurich)
eu-north-1	Europe (Stockholm)
eu-south-1	Europe (Milan)
eu-south-2	Europe (Spain)
eu-west-1	Europe (Ireland)
eu-west-2	Europe (London)
eu-west-3	Europe (Paris)
eusc-de-east-1	AWS European Sovereign Cloud (Germany)
il-central-1	Israel (Tel Aviv)
me-central-1	Middle East (UAE)

AWS Region code	AWS Region name
me-south-1	Middle East (Bahrain)
mx-central-1	Mexico (Central)
sa-east-1	South America (São Paulo)
us-gov-east-1	AWS GovCloud (US-East)
us-gov-west-1	AWS GovCloud (US-West)

S3 Access Grants integrations

S3 Access Grants can be used with the following AWS services and features. This page will be updated as new integrations become available.

> **Tip**
>
> This AWS workshop for S3 Access Grants walks you through using S3 Access Grants with AWS Identity and Access Management (IAM) users, IAM Identity Center users, Amazon EMR, and AWS Transfer Family.

Amazon Athena

- Using IAM Identity Center enabled Athena workgroups

Amazon EMR

- Launch an Amazon EMR cluster with S3 Access Grants

Amazon EMR on EKS

- Launch an Amazon EMR on EKS cluster with S3 Access Grants

Amazon EMR Serverless application

- Launch an Amazon EMR Serverless application with S3 Access Grants

Amazon Redshift

- Amazon Redshift integration with Amazon S3 Access Grants

Amazon SageMaker AI Studio

Adding Amazon S3 data to Amazon SageMaker AI Unified Studio

Using S3 Access Grants in Amazon SageMaker AI Unified Studio, you can share your Amazon S3 data in multiple projects. To enable granting access to data using S3 Access Grants, an S3 Access Grants instance is required. Amazon SageMaker AI Unified Studio will use an S3 Access Grants instance if one is already available or can create an instance. First, you add your Amazon S3 data and then publish the data to the catalog or share it directly with consumers.

Using Amazon S3 Access Grants with Amazon SageMaker AI Studio and the SDK for Python (Boto3) plugin

Using S3 Access Grants in Amazon SageMaker AI Studio notebooks is now easier when using the SDK for Python (Boto3) plugin. Set up access grants for IAM principals and AWS IAM Identity Center directory users, beforehand. Although Amazon SageMaker AI Studio does not natively support identity provider directory users, you can write custom Python code, using the plugin that allows these identities to access S3 data through S3 Access Grants. The data access is taking place with the help of the plugin and not through Amazon SageMaker AI.

AWS Glue

Amazon S3 Access Grants with AWS Glue

AWS IAM Identity Center

Trusted identity propagation across applications

AWS Transfer Family

Configure Amazon S3 Access Grants for AWS Transfer Family

Storage Browser for S3

Managing data access at scale using Storage Browser for S3

Open source Python frameworks

Amazon S3 Access Grants now integrates with open source Python frameworks

Managing access with ACLs

Access control lists (ACLs) are one of the resource-based options that you can use to manage access to your buckets and objects. You can use ACLs to grant basic read/write permissions to other AWS accounts. There are limits to managing permissions using ACLs.

For example, you can grant permissions only to other AWS accounts; you cannot grant permissions to users in your account. You cannot grant conditional permissions, nor can you explicitly deny permissions. ACLs are suitable for specific scenarios. For example, if a bucket owner allows other AWS accounts to upload objects, permissions to these objects can only be managed using object ACL by the AWS account that owns the object.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

For more information about ACLs, see the following topics.

Topics

- Access control list (ACL) overview
- Configuring ACLs

- Policy examples for ACLs

Access control list (ACL) overview

Amazon S3 access control lists (ACLs) enable you to manage access to buckets and objects. Each bucket and object has an ACL attached to it as a subresource. It defines which AWS accounts or groups are granted access and the type of access. When a request is received against a resource, Amazon S3 checks the corresponding ACL to verify that the requester has the necessary access permissions.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

When you create a bucket or an object, Amazon S3 creates a default ACL that grants the resource owner full control over the resource. This is shown in the following sample bucket ACL (the default object ACL has the same structure):

Example

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>*** Owner-Canonical-User-ID ***</ID>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
               xsi:type="Canonical User">
        <ID>*** Owner-Canonical-User-ID ***</ID>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

The sample ACL includes an `Owner` element that identifies the owner by the AWS account's canonical user ID. For instructions on finding your canonical user ID, see Finding an AWS account canonical user ID. The `Grant` element identifies the grantee (either an AWS account or a predefined group) and the permission granted. This default ACL has one `Grant` element for the owner. You grant permissions by adding `Grant` elements, with each grant identifying the grantee and the permission.

> **Note**
>
> An ACL can have up to 100 grants.

Topics

- Who is a grantee?
- What permissions can I grant?
- aclRequired values for common Amazon S3 requests
- Sample ACL
- Canned ACL

Who is a grantee?

When you grant access rights, you specify each grantee as a *type*="*value*" pair, where *type* is one of the following:

- `id` – If the value specified is the canonical user ID of an AWS account
- `uri` – If you are granting permissions to a predefined group

> **Warning**
>
> When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see Creating a Role to Delegate Permissions to an IAM User in the *IAM User Guide*.

Finding an AWS account canonical user ID

The canonical user ID is associated with your AWS account. This ID is a long string of characters, such as:

`79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be`

For information about how to find the canonical user ID for your account, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.

You can also look up the canonical user ID of an AWS account by reading the ACL of a bucket or an object to which the AWS account has access permissions. When an individual AWS account is granted permissions by a grant request, a grant entry is added to the ACL with the account's canonical user ID.

> **Note**
>
> If you make your bucket public (not recommended), any unauthenticated user can upload objects to the bucket. These anonymous users don't have an AWS account. When an anonymous user uploads an object to your bucket, Amazon S3 adds a special canonical user ID (`65a011a29cdf8ec533ec3d1ccaae921c`) as the object owner in the ACL. For more information, see Amazon S3 bucket and object ownership.

Amazon S3 predefined groups

Amazon S3 has a set of predefined groups. When granting account access to a group, you specify one of the Amazon S3 URIs instead of a canonical user ID. Amazon S3 provides the following predefined groups:

- **Authenticated Users group** – Represented by `http://acs.amazonaws.com/groups/global/AuthenticatedUsers`.

  This group represents all AWS accounts. **Access permission to this group allows any AWS account to access the resource.** However, all requests must be signed (authenticated).

  > **Warning**
  >
  > When you grant access to the **Authenticated Users group**, any AWS authenticated user in the world can access your resource.

- **All Users group** – Represented by `http://acs.amazonaws.com/groups/global/AllUsers`.

  Access permission to this group allows anyone in the world access to the resource. The requests can be signed (authenticated) or unsigned (anonymous). Unsigned requests omit the Authentication header in the request.

  > **Warning**
  >
  > We highly recommend that you never grant the **All Users group** `WRITE`, `WRITE_ACP`, or `FULL_CONTROL` permissions. For example, although `WRITE` permissions deny non-owners the ability to overwrite or delete existing objects, `WRITE` permissions still allow anyone to store objects in your bucket, for which you are billed. For more details about these permissions, see the following section What permissions can I grant?.

- **Log Delivery group** – Represented by `http://acs.amazonaws.com/groups/s3/LogDelivery`.

  `WRITE` permission on a bucket enables this group to write server access logs (see Logging requests with server access logging) to the bucket.

> **Note**
>
> When using ACLs, a grantee can be an AWS account or one of the predefined Amazon S3 groups. However, the grantee cannot be an IAM user. For more information about AWS users and permissions within IAM, see Using AWS Identity and Access Management.

What permissions can I grant?

The following table lists the set of permissions that Amazon S3 supports in an ACL. The set of ACL permissions is the same for an object ACL and a bucket ACL. However, depending on the context (bucket ACL or object ACL), these ACL permissions grant permissions for specific buckets or object operations. The table lists the permissions and describes what they mean in the context of objects and buckets.

For more information about ACL permissions in the Amazon S3 console, see Configuring ACLs.

Permission	When granted on a bucket	When granted on an object
`READ`	Allows grantee to list the objects in the bucket	Allows grantee to read the object data and its metadata
`WRITE`	Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects	Not applicable
`READ_ACP`	Allows grantee to read the bucket ACL	Allows grantee to read the object ACL
`WRITE_ACP`	Allows grantee to write the ACL for the applicable bucket	Allows grantee to write the ACL for the applicable object
`FULL_CONTROL`	Allows grantee the `READ`, `WRITE`, `READ_ACP`, and `WRITE_ACP` permissions on the bucket	Allows grantee the `READ`, `READ_ACP`, and `WRITE_ACP` permissions on the object

Warning

Use caution when granting access permissions to your S3 buckets and objects. For example, granting `WRITE` access to a bucket allows the grantee to create objects in the bucket. We highly recommend that you read through the entire Access control list (ACL) overview section before granting permissions.

Mapping of ACL permissions and access policy permissions

As shown in the preceding table, an ACL allows only a finite set of permissions, compared to the number of permissions that you can set in an access policy (see Policy actions for Amazon S3). Each of these permissions allows one or more Amazon S3 operations.

The following table shows how each ACL permission maps to the corresponding access policy permissions. As you can see, access policy allows more permissions than an ACL does. You use ACLs primarily to grant basic read/write permissions, similar to file system permissions. For more information about when to use an ACL, see Identity and Access Management for Amazon S3.

For more information about ACL permissions in the Amazon S3 console, see Configuring ACLs.

ACL permission	Corresponding access policy permissions when the ACL permission is granted on a bucket	Corresponding access policy permissions when the ACL permission is granted on an object
`READ`	`s3:ListBucket` , `s3:ListBucketVersions` , and `s3:ListBucketMultipartUploads`	`s3:GetObject` and `s3:GetObjectVersion`
`WRITE`	`s3:PutObject` Bucket owner can create, overwrite, and delete any object in the bucket, and object owner has `FULL_CONTROL` over their object. In addition, when the grantee is the bucket owner, granting `WRITE` permission in a bucket ACL allows	Not applicable

ACL permission	Corresponding access policy permissions when the ACL permission is granted on a bucket	Corresponding access policy permissions when the ACL permission is granted on an object
	the `s3:DeleteObjectVersion` action to be performed on any version in that bucket.	
`READ_ACP`	`s3:GetBucketAcl`	`s3:GetObjectAcl` and `s3:GetObjectVersionAcl`
`WRITE_ACP`	`s3:PutBucketAcl`	`s3:PutObjectAcl` and `s3:PutObjectVersionAcl`
`FULL_CONTROL`	Equivalent to granting `READ`, `WRITE`, `READ_ACP`, and `WRITE_ACP` ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions.	Equivalent to granting `READ`, `READ_ACP`, and `WRITE_ACP` ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions.

Condition keys

When you grant access policy permissions, you can use condition keys to constrain the value for the ACL on an object using a bucket policy. The following context keys correspond to ACLs. You can use these context keys to mandate the use of a specific ACL in a request:

- `s3:x-amz-grant-read` - Require read access.
- `s3:x-amz-grant-write` - Require write access.
- `s3:x-amz-grant-read-acp` - Require read access to the bucket ACL.
- `s3:x-amz-grant-write-acp` - Require write access to the bucket ACL.
- `s3:x-amz-grant-full-control` - Require full control.
- `s3:x-amz-acl` - Require a Canned ACL.

For example policies that involve ACL-specific headers, see Granting s3:PutObject permission with a condition requiring the bucket owner to get full control. For a complete list of Amazon S3

specific condition keys, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

`aclRequired` values for common Amazon S3 requests

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. The `aclRequired` value that appears in CloudTrail or Amazon S3 server access logs depends on which operations were called and certain information about the requester, object owner, and bucket owner. If no ACLs were required, or if you are setting the `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is "`-`" in Amazon S3 server access logs and is absent in CloudTrail.

The following tables list the expected `aclRequired` values in CloudTrail or Amazon S3 server access logs for the various Amazon S3 API operations. You can use this information to understand which Amazon S3 operations depend on ACLs for authorization. In the following tables, A, B, and C represent the different accounts associated with the requester, object owner, and bucket owner. Entries with an asterisk (*) indicate any of accounts A, B, or C.

> **Note**
>
> `PutObject` operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a `bucket-owner-full-control` ACL. A null value for `aclRequired` indicates that `aclRequired` is absent in AWS CloudTrail logs.

The following table shows the `aclRequired` values for CloudTrail.

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	`aclRequired` value	Reason
`GetObject`	A	A	A	Yes or No	null	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	B	A	Yes or No	null	Same-account access with bucket owner enforced
GetObject	A	A	B	Yes	null	Cross-account access granted by bucket policy
GetObject	A	A	B	No	Yes	Cross-account access relies on ACL
GetObject	A	A	B	Yes	null	Cross-account access granted by bucket policy
GetObject	A	B	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	B	C	Yes	null	Cross-account access granted by bucket policy
GetObject	A	B	C	No	Yes	Cross-account access relies on ACL
PutObject	A	Not applicable	A	Yes or No	null	Same-account access
PutObject	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
PutObject	A	Not applicable	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
PutObject with an ACL (except for bucket-owner-full-control)	*	Not applicable	*	Yes or No	Yes	Request grants ACL
ListObjects	A	Not applicable	A	Yes or No	null	Same-account access
ListObjects	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
ListObjects	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
DeleteObject	A	Not applicable	A	Yes or No	null	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
DeleteObject	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
DeleteObject	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
PutObjectAcl	*	*	*	Yes or No	Yes	Request grants ACL
PutBucketAcl	*	Not applicable	*	Yes or No	Yes	Request grants ACL

Note

REST.PUT.OBJECT operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a bucket-owner-full-control ACL. An aclRequired value string of "-" indicates a null value in Amazon S3 server access logs.

The following table shows the aclRequired values for Amazon S3 server access logs.

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.GET.OBJECT	A	A	A	Yes or No	-	Same-account access
REST.GET.OBJECT	A	B	A	Yes or No	-	Same-account access with bucket owner enforced
REST.GET.OBJECT	A	A	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	A	B	No	Yes	Cross-account access relies on ACL
REST.GET.OBJECT	A	B	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	B	B	No	Yes	Cross-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
						relies on ACL
REST.GET.OBJECT	A	B	C	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	B	C	No	Yes	Cross-account access relies on ACL
REST.PUT.OBJECT	A	Not applicable	A	Yes or No	-	Same-account access
REST.PUT.OBJECT	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.PUT.OBJECT	A	Not applicable	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.PUT.OBJECT with an ACL (except for bucket-owner-full-control)	*	Not applicable	*	Yes or No	Yes	Request grants ACL
REST.GET.BUCKET	A	Not applicable	A	Yes or No	-	Same-account access
REST.GET.BUCKET	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.BUCKET	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
REST.DELETE.OBJECT	A	Not applicable	A	Yes or No	-	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.DELETE.OBJECT	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.DELETE.OBJECT	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
REST.PUT.ACL	*	*	*	Yes or No	Yes	Request grants ACL

Sample ACL

The following sample ACL on a bucket identifies the resource owner and a set of grants. The format is the XML representation of an ACL in the Amazon S3 REST API. The bucket owner has FULL_CONTROL of the resource. In addition, the ACL shows how permissions are granted on a resource to two AWS accounts, identified by canonical user ID, and two of the predefined Amazon S3 groups discussed in the preceding section.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>Owner-canonical-user-ID</ID>
  </Owner>
  <AccessControlList>
    <Grant>
```

```
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:type="CanonicalUser">
        <ID>Owner-canonical-user-ID</ID>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>

    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:type="CanonicalUser">
        <ID>user1-canonical-user-ID</ID>
      </Grantee>
      <Permission>WRITE</Permission>
    </Grant>

    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:type="CanonicalUser">
        <ID>user2-canonical-user-ID</ID>
      </Grantee>
      <Permission>READ</Permission>
    </Grant>

    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
      </Grantee>
      <Permission>READ</Permission>
    </Grant>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
      </Grantee>
      <Permission>WRITE</Permission>
    </Grant>

  </AccessControlList>
</AccessControlPolicy>
```

Canned ACL

Amazon S3 supports a set of predefined grants, known as *canned ACLs*. Each canned ACL has a predefined set of grantees and permissions. The following table lists the set of canned ACLs and the associated predefined grants.

Canned ACL	Applies to	Permissions added to ACL
`private`	Bucket and object	Owner gets `FULL_CONTROL`. No one else has access rights (default).
`public-read`	Bucket and object	Owner gets `FULL_CONTROL`. The `AllUsers` group (see Who is a grantee?) gets `READ` access.
`public-read-write`	Bucket and object	Owner gets `FULL_CONTROL`. The `AllUsers` group gets `READ` and `WRITE` access. Granting this on a bucket is generally not recommended.
`aws-exec-read`	Bucket and object	Owner gets `FULL_CONTROL`. Amazon EC2 gets `READ` access to `GET` an Amazon Machine Image (AMI) bundle from Amazon S3.
`authenticated-read`	Bucket and object	Owner gets `FULL_CONTROL`. The `AuthenticatedUsers` group gets `READ` access.
`bucket-owner-read`	Object	Object owner gets `FULL_CONTROL`. Bucket owner gets `READ` access. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it.
`bucket-owner-full-control`	Object	Both the object owner and the bucket owner get `FULL_CONTROL` over the object. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it.

Canned ACL	Applies to	Permissions added to ACL
`log-delivery-write`	Bucket	The `LogDelivery` group gets `WRITE` and `READ_ACP` permissions on the bucket. For more information about logs, see (Logging requests with server access logging).

> **Note**
>
> You can specify only one of these canned ACLs in your request.

You specify a canned ACL in your request by using the `x-amz-acl` request header. When Amazon S3 receives a request with a canned ACL in the request, it adds the predefined grants to the ACL of the resource.

Configuring ACLs

This section explains how to manage access permissions for S3 buckets and objects using access control lists (ACLs). You can add grants to your resource ACL using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs.

Bucket and object permissions are independent of each other. An object does not inherit the permissions from its bucket. For example, if you create a bucket and grant write access to a user, you can't access that user's objects unless the user explicitly grants you access.

You can grant permissions to other AWS account users or to predefined groups. The user or group that you are granting permissions to is called the *grantee*. By default, the owner, which is the AWS account that created the bucket, has full permissions.

Each permission you grant for a user or group adds an entry in the ACL that is associated with the bucket. The ACL lists grants, which identify the grantee and the permission granted.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled.

When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Warning

Do not grant write access to the **Everyone (public access)** or **Authenticated Users group (all AWS authenticated users)** groups. For more information about the effects of granting write access to these groups, see Amazon S3 predefined groups.

Using the S3 console to set ACL permissions for a bucket

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs.

The following table shows the ACL permissions that you can configure for buckets in the Amazon S3 console.

Amazon S3 console ACL permissions for buckets

Console permission	ACL permission	Access
Objects - List	READ	Allows grantee to list the objects in the bucket.

Console permission	ACL permission	Access
Objects - Write	`WRITE`	Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.
Bucket ACL - Read	`READ_ACP`	Allows grantee to read the bucket ACL.
Bucket ACL - Write	`WRITE_ACP`	Allows grantee to write the ACL for the applicable bucket.
Everyone (public access): Objects - List	`READ`	Grants public read access for the objects in the bucket. When you grant list access to **Everyone (public access)**, anyone in the world can access the objects in the bucket.
Everyone (public access): Bucket ACL - Read	`READ_ACP`	Grants public read access for the bucket ACL. When you grant read access to **Everyone (public access)**, anyone in the world can access the bucket ACL.

For more information about ACL permissions, see Access control list (ACL) overview.

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To set ACL permissions for a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set permissions for.
4. Choose **Permissions**.
5. Under **Access control list**, choose **Edit**.

   You can edit the following ACL permissions for the bucket:

   Objects

   - **List** – Allows a grantee to list the objects in the bucket.
   - **Write** – Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.

     In the S3 console, you can only grant write access to the S3 log delivery group and the bucket owner (your AWS account). Do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.

   Bucket ACL

   - **Read** – Allows grantee to read the bucket ACL.
   - **Write** – Allows grantee to write the ACL for the applicable bucket.
6. To change the bucket owner's permissions, beside **Bucket owner (your AWS account)**, clear or select from the following ACL permissions:

   - **Objects** – **List** or **Write**
   - **Bucket ACL** – **Read** or **Write**

   The *owner* refers to the AWS account root user, not an AWS Identity and Access Management IAM user. For more information about the root user, see The AWS account root user in the *IAM User Guide*.
7. To grant or undo permissions for the general public (everyone on the internet), beside **Everyone (public access)**, clear or select from the following ACL permissions:

- **Objects** – **List**
- **Bucket ACL** – **Read**

> **Warning**
>
> Use caution when granting the **Everyone** group public access to your S3 bucket. When you grant access to this group, anyone in the world can access your bucket. Never grant any kind of public write access to your S3 bucket.

8. To grant or undo permissions for anyone with an AWS account, beside **Authenticated Users group (anyone with an AWS account)**, clear or select from the following ACL permissions:

   - **Objects** – **List**
   - **Bucket ACL** – **Read**

9. To grant or undo permissions for Amazon S3 to write server access logs to the bucket, under **S3 log delivery group**, clear or select from the following ACL permissions:

   - **Objects** – **List** or **Write**
   - **Bucket ACL** – **Read** or **Write**

   If a bucket is set up as the target to receive access logs, the bucket permissions must allow the **Log Delivery** group write access. When you enable server access logging on a bucket, the Amazon S3 console grants write access to the **Log Delivery** group for the target bucket that you choose. For more information about server access logging, see Enabling Amazon S3 server access logging.

10. To grant access to another AWS account, do the following:

    a. Choose **Add grantee**.

    b. In the **Grantee** box, enter the canonical ID of the other AWS account.

    c. Select from the following ACL permissions:

       - **Objects** – **List** or **Write**
       - **Bucket ACL** – **Read** or **Write**

> **Warning**
>
> When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see Creating a Role to Delegate Permissions to an IAM User in the *IAM User Guide*.

11. To remove access to another AWS account, under **Access for other AWS accounts**, choose **Remove**.
12. To save your changes, choose **Save changes**.

Using the S3 console to set ACL permissions for an object

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs. The following table shows the ACL permissions that you can configure for objects in the Amazon S3 console.

Amazon S3 console ACL permissions for objects

Console permission	ACL permission	Access
Object - Read	`READ`	Allows grantee to read the object data and its metadata.
Object ACL - Read	`READ_ACP`	Allows grantee to read the object ACL.
Object ACL - Write	`WRITE_ACP`	Allows grantee to write the ACL for the applicable object

For more information about ACL permissions, see Access control list (ACL) overview.

> **Important**
>
> If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control

lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To set ACL permissions for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **objects** list, choose the name of the object for which you want to set permissions.
4. Choose **Permissions**.
5. Under Access control list (ACL), choose **Edit**.

   You can edit the following ACL permissions for the object:

   Object

   - **Read** – Allows grantee to read the object data and its metadata.

   Object ACL

   - **Read** – Allows grantee to read the object ACL.
   - **Write** – Allows grantee to write the ACL for the applicable object. In the S3 console, you can only grant write access to the bucket owner (your AWS account). Do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.
6. You can manage object access permissions for the following:

   a. **Access for object owner**

      The *owner* refers to the AWS account root user, and not an AWS Identity and Access Management IAM user. For more information about the root user, see The AWS account root user in the *IAM User Guide*.

      To change the owner's object access permissions, under **Access for object owner**, choose **Your AWS Account (owner)**.

Select the check boxes for the permissions that you want to change, and then choose **Save**.

b. **Access for other AWS accounts**

To grant permissions to an AWS user from a different AWS account, under **Access for other AWS accounts**, choose **Add account**. In the **Enter an ID** field, enter the canonical ID of the AWS user that you want to grant object permissions to. For information about finding a canonical ID, see Your AWS account identifiers in the *Amazon Web Services General Reference*. You can add as many as 99 users.

Select the check boxes for the permissions that you want to grant to the user, and then choose **Save**. To display information about the permissions, choose the Help icons.

c. **Public access**

To grant access to your object to the general public (everyone in the world), under **Public access**, choose **Everyone**. Granting public access permissions means that anyone in the world can access the object.

Select the check boxes for the permissions that you want to grant, and then choose **Save**.

> **Warning**
>
> - Use caution when granting the **Everyone** group anonymous access to your Amazon S3 objects. When you grant access to this group, anyone in the world can access your object. If you need to grant access to everyone, we highly recommend that you only grant permissions to **Read objects**.
> - *Do not* grant the **Everyone** group write object permissions. Doing so allows anyone to overwrite the ACL permissions for the object.

Using the AWS SDKs

The following examples show how to set access control list (ACL) grants on buckets and objects.

Important

If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Java

The following examples show how to set access control list (ACL) grants on buckets and objects. The first example creates a bucket with a canned ACL (see Canned ACL), creates a list of custom grants, and then replaces the canned ACL with the custom grants. The second example shows how to modify an ACL using the `AccessControlList.grantPermission()` method.

Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group

This example creates a bucket. In the request, the example specifies a canned ACL that grants the Log Delivery group permission to write logs to the bucket.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.IOException;
import java.util.ArrayList;

public class CreateBucketWithACL {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String userEmailForReadPermission = "*** user@example.com ***";

        try {
```

```
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .build();

            // Create a bucket with a canned ACL. This ACL will be replaced by the
            // setBucketAcl()
            // calls below. It is included here for demonstration purposes.
            CreateBucketRequest createBucketRequest = new
CreateBucketRequest(bucketName, clientRegion.getName())
                    .withCannedAcl(CannedAccessControlList.LogDeliveryWrite);
            s3Client.createBucket(createBucketRequest);

            // Create a collection of grants to add to the bucket.
            ArrayList<Grant> grantCollection = new ArrayList<Grant>();

            // Grant the account owner full control.
            Grant grant1 = new Grant(new
CanonicalGrantee(s3Client.getS3AccountOwner().getId()),
                    Permission.FullControl);
            grantCollection.add(grant1);

            // Grant the LogDelivery group permission to write to the bucket.
            Grant grant2 = new Grant(GroupGrantee.LogDelivery, Permission.Write);
            grantCollection.add(grant2);

            // Save grants by replacing all current ACL grants with the two we just
created.
            AccessControlList bucketAcl = new AccessControlList();
            bucketAcl.grantAllPermissions(grantCollection.toArray(new Grant[0]));
            s3Client.setBucketAcl(bucketName, bucketAcl);

            // Retrieve the bucket's ACL, add another grant, and then save the new
ACL.
            AccessControlList newBucketAcl = s3Client.getBucketAcl(bucketName);
            Grant grant3 = new Grant(new
EmailAddressGrantee(userEmailForReadPermission), Permission.Read);
            newBucketAcl.grantAllPermissions(grant3);
            s3Client.setBucketAcl(bucketName, newBucketAcl);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
```

```
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example Update ACL on an existing object

This example updates the ACL on an object. The example performs the following tasks:

- Retrieves an object's ACL
- Clears the ACL by removing all existing permissions
- Adds two permissions: full access to the owner, and WRITE_ACP (see What permissions can I grant?) to a user identified by an email address
- Saves the ACL to the object

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.AccessControlList;
import com.amazonaws.services.s3.model.CanonicalGrantee;
import com.amazonaws.services.s3.model.EmailAddressGrantee;
import com.amazonaws.services.s3.model.Permission;

import java.io.IOException;

public class ModifyACLExistingObject {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String keyName = "*** Key name ***";
        String emailGrantee = "*** user@example.com ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
```

```
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            // Get the existing object ACL that we want to modify.
            AccessControlList acl = s3Client.getObjectAcl(bucketName, keyName);

            // Clear the existing list of grants.
            acl.getGrantsAsList().clear();

            // Grant a sample set of permissions, using the existing ACL owner for
 Full
            // Control permissions.
            acl.grantPermission(new CanonicalGrantee(acl.getOwner().getId()),
 Permission.FullControl);
            acl.grantPermission(new EmailAddressGrantee(emailGrantee),
 Permission.WriteAcp);

            // Save the modified ACL back to the object.
            s3Client.setObjectAcl(bucketName, keyName, acl);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group

This C# example creates a bucket. In the request, the code also specifies a canned ACL that grants the Log Delivery group permissions to write the logs to the bucket.

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingBucketACLTest
    {
        private const string newBucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            CreateBucketUseCannedACLAsync().Wait();
        }

        private static async Task CreateBucketUseCannedACLAsync()
        {
            try
            {
                // Add bucket (specify canned ACL).
                PutBucketRequest putBucketRequest = new PutBucketRequest()
                {
                    BucketName = newBucketName,
                    BucketRegion = S3Region.EUW1, // S3Region.US,
                                                  // Add canned ACL.
                    CannedACL = S3CannedACL.LogDeliveryWrite
                };
                PutBucketResponse putBucketResponse = await
 client.PutBucketAsync(putBucketRequest);

                // Retrieve bucket ACL.
                GetACLResponse getACLResponse = await client.GetACLAsync(new
 GetACLRequest
                {
                    BucketName = newBucketName
                });
```

```
            }
            catch (AmazonS3Exception amazonS3Exception)
            {
                Console.WriteLine("S3 error occurred. Exception: " +
 amazonS3Exception.ToString());
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: " + e.ToString());
            }
        }
    }
}
```

Example Update ACL on an existing object

This C# example updates the ACL on an existing object. The example performs the following tasks:

- Retrieves an object's ACL.
- Clears the ACL by removing all existing permissions.
- Adds two permissions: full access to the owner, and WRITE_ACP to a user identified by email address.
- Saves the ACL by sending a `PutAcl` request.

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingObjectACLTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** object key name ***";
```

```
        private const string emailAddress = "*** email address ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            TestObjectACLTestAsync().Wait();
        }
        private static async Task TestObjectACLTestAsync()
        {
            try
            {
                    // Retrieve the ACL for the object.
                    GetACLResponse aclResponse = await client.GetACLAsync(new
GetACLRequest
                    {
                        BucketName = bucketName,
                        Key = keyName
                    });

                    S3AccessControlList acl = aclResponse.AccessControlList;

                    // Retrieve the owner (we use this to re-add permissions after
we clear the ACL).
                    Owner owner = acl.Owner;

                    // Clear existing grants.
                    acl.Grants.Clear();

                    // Add a grant to reset the owner's full permission (the
previous clear statement removed all permissions).
                    S3Grant fullControlGrant = new S3Grant
                    {
                        Grantee = new S3Grantee { CanonicalUser = owner.Id },
                        Permission = S3Permission.FULL_CONTROL

                    };

                    // Describe the grant for the permission using an email address.
                    S3Grant grantUsingEmail = new S3Grant
                    {
                        Grantee = new S3Grantee { EmailAddress = emailAddress },
```

```
                        Permission = S3Permission.WRITE_ACP
                    };
                    acl.Grants.AddRange(new List<S3Grant> { fullControlGrant,
 grantUsingEmail });

                    // Set a new ACL.
                    PutACLResponse response = await client.PutACLAsync(new
 PutACLRequest
                    {
                        BucketName = bucketName,
                        Key = keyName,
                        AccessControlList = acl
                    });
            }
            catch (AmazonS3Exception amazonS3Exception)
            {
                Console.WriteLine("An AmazonS3Exception was thrown. Exception: " +
 amazonS3Exception.ToString());
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: " + e.ToString());
            }
        }
    }
}
```

Using the REST API

Amazon S3 APIs enable you to set an ACL when you create a bucket or an object. Amazon S3 also provides API to set an ACL on an existing bucket or an object. These APIs provide the following methods to set an ACL:

- **Set ACL using request headers—** When you send a request to create a resource (bucket or object), you set an ACL using the request headers. Using these headers, you can either specify a canned ACL or specify grants explicitly (identifying grantee and permissions explicitly).
- **Set ACL using request body—** When you send a request to set an ACL on an existing resource, you can set the ACL either in the request header or in the body.

For information on the REST API support for managing ACLs, see the following sections in the *Amazon Simple Storage Service API Reference*:

- GetBucketAcl
- PutBucketAcl
- GetObjectAcl
- PutObjectAcl
- PutObject
- CreateBucket
- CopyObject
- CreateMultipartUpload

> **Important**
>
> If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Access Control List (ACL)-Specific Request Headers

You can use headers to grant access control list (ACL)-based permissions. By default, all objects are private. Only the owner has full access control. When you add a new object, you can grant permissions to individual AWS accounts or to predefined groups that Amazon S3 defines. These permissions are then added to the ACL on the object. For more information, see Access control list (ACL) overview.

With this operation, you can grant access permissions using one these two methods:

- **Canned ACL (`x-amz-acl`)** — Amazon S3 supports a set of predefined ACLs, known as canned ACLs. Each canned ACL has a predefined set of grantees and permissions. For more information, see Canned ACL.
- **Access Permissions** — To explicitly grant access permissions to specific AWS accounts or groups, use the following headers. Each header maps to specific permissions that Amazon S3 supports in

an ACL. For more information, see Access control list (ACL) overview. In the header, you specify a list of grantees who get the specific permission.

- x-amz-grant-read
- x-amz-grant-write
- x-amz-grant-read-acp
- x-amz-grant-write-acp
- x-amz-grant-full-control

Using the AWS CLI

For more information about managing ACLs using the AWS CLI, see put-bucket-acl in the *AWS CLI Command Reference*.

> **Important**
>

With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Policy examples for ACLs

You can use condition keys in bucket policies to control access to Amazon S3.

Topics

- Granting s3:PutObject permission with a condition requiring the bucket owner to get full control
- Granting s3:PutObject permission with a condition on the x-amz-acl header

Granting s3:PutObject permission with a condition requiring the bucket owner to get full control

The PUT Object operation allows access control list (ACL)–specific headers that you can use to grant ACL-based permissions. Using these keys, the bucket owner can set a condition to require specific access permissions when the user uploads an object.

Suppose that Account A owns a bucket, and the account administrator wants to grant Dave, a user in Account B, permissions to upload objects. By default, objects that Dave uploads are owned by Account B, and Account A has no permissions on these objects. Because the bucket owner is paying the bills, it wants full permissions on the objects that Dave uploads. The Account A administrator can do this by granting the `s3:PutObject` permission to Dave, with a condition that the request include ACL-specific headers that either grant full permission explicitly or use a canned ACL. For more information, see PUT Object.

Require the x-amz-full-control header

You can require the `x-amz-full-control` header in the request with full control permission to the bucket owner. The following bucket policy grants the `s3:PutObject` permission to user Dave with a condition using the `s3:x-amz-grant-full-control` condition key, which requires the request to include the `x-amz-full-control` header.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/Dave"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
                }
            }
        }
    ]
}
```

> **Note**
>
> This example is about cross-account permission. However, if Dave (who is getting the permission) belongs to the AWS account that owns the bucket, this conditional permission is not necessary. This is because the parent account to which Dave belongs owns objects that the user uploads.

Add explicit deny

The preceding bucket policy grants conditional permission to user Dave in Account B. While this policy is in effect, it is possible for Dave to get the same permission without any condition through some other policy. For example, Dave can belong to a group, and you grant the group `s3:PutObject` permission without any condition. To avoid such permission loopholes, you can write a stricter access policy by adding explicit deny. In this example, you explicitly deny the user Dave upload permission if he does not include the necessary headers in the request granting full permissions to the bucket owner. Explicit deny always supersedes any other permission granted. The following is the revised access policy example with explicit deny added.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
                }
            }
        },
        {
            "Sid": "statement2",
```

```
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringNotEquals": {
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
                }
            }
        }
    ]
}
```

Test the policy with the AWS CLI

If you have two AWS accounts, you can test the policy using the AWS Command Line Interface (AWS CLI). You attach the policy and use Dave's credentials to test the permission using the following AWS CLI `put-object` command. You provide Dave's credentials by adding the `--profile` parameter. You grant full control permission to the bucket owner by adding the `--grant-full-control` parameter. For more information about setting up and using the AWS CLI, see Developing with Amazon S3 using the AWS CLI in the *Amazon S3 API Reference*.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg
 --grant-full-control id="AccountA-CanonicalUserID" --profile AccountBUserProfile
```

Require the x-amz-acl header

You can require the `x-amz-acl` header with a canned ACL granting full control permission to the bucket owner. To require the `x-amz-acl` header in the request, you can replace the key-value pair in the `Condition` block and specify the `s3:x-amz-acl` condition key, as shown in the following example.

```
"Condition": {
    "StringEquals": {
        "s3:x-amz-acl": "bucket-owner-full-control"
    }
}
```

To test the permission using the AWS CLI, you specify the `--acl` parameter. The AWS CLI then adds the `x-amz-acl` header when it sends the request.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg
 --acl "bucket-owner-full-control" --profile AccountBadmin
```

Granting s3:PutObject permission with a condition on the x-amz-acl header

The following bucket policy grants the `s3:PutObject` permission for two AWS accounts if the request includes the `x-amz-acl` header making the object publicly readable. The `Condition` block uses the `StringEquals` condition, and it is provided a key-value pair, `"s3:x-amz-acl": ["public-read"]`, for evaluation. In the key-value pair, the `s3:x-amz-acl` is an Amazon S3–specific key, as indicated by the prefix `s3:`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AddCannedAcl",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root",
                    "arn:aws:iam::111122223333:root"
                ]
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::awsexamplebucket1/*"
            ],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": [
                        "public-read"
                    ]
                }
            }
        }
    ]
```

```
}
```

Important

Not all conditions make sense for all actions. For example, it makes sense to include an `s3:LocationConstraint` condition on a policy that grants the `s3:CreateBucket` Amazon S3 permission. However, it does not make sense to include this condition on a policy that grants the `s3:GetObject` permission. Amazon S3 can test for semantic errors of this type that involve Amazon S3–specific conditions. However, if you are creating a policy for an IAM user or role and you include a semantically invalid Amazon S3 condition, no error is reported because IAM cannot validate Amazon S3 conditions.

Blocking public access to your Amazon S3 storage

The Amazon S3 Block Public Access feature provides settings for access points, buckets, accounts, and AWS Organizations to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, or object permissions to allow public access. S3 Block Public Access settings override these policies and permissions so that you can limit public access to these resources.

With S3 Block Public Access, organization administrators, account administrators, and bucket owners can easily set up centralized controls to limit public access to their Amazon S3 resources that are enforced regardless of how the resources are created.

You can manage Block Public Access settings at multiple levels: organization level (using AWS Organizations), account level, and bucket and access point level. For instructions on configuring public block access, see Configuring block public access.

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the account is part of an AWS Organizations with Block Public Access policies, Amazon S3 also checks for organization-level settings. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. At the organization level, all four settings are applied together as a unified policy - you cannot select individual settings granularly. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings. Account-level settings automatically inherit organization-level policies when present, and S3 takes the most restrictive policy between bucket-level and effective account-level settings. For example, if your organization has a Block Public Access policy enabled, but a specific bucket has Block Public Access disabled at the bucket level, the bucket will still be protected because S3 applies the more restrictive organization/account-level settings. Conversely, if your organization policy is disabled but a bucket has Block Public Access enabled, that bucket remains protected by its bucket-level settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an organization policy (which enforces the account BPA setting) or an access point, bucket, or account setting.

Important

Public access is granted to buckets and objects through access control lists (ACLs), access point policies, bucket policies, or all. To help ensure that all of your Amazon S3 access points, buckets, and objects have their public access blocked, we recommend that you turn on all four settings for block public access for your account. For organizations managing multiple accounts, consider using organization-level Block Public Access policies for centralized control. Additionally, we recommend that you also turn on all four settings for each bucket to comply with AWS Security Hub Foundational Security Best Practices control S3.8. These settings block public access for all current and future buckets and access points. Before applying these settings, verify that your applications will work correctly without public access. If you require some level of public access to your buckets or objects, for example to host a static website as described at Hosting a static website using Amazon S3, you can customize the individual settings to suit your storage use cases.
Enabling Block Public Access helps protect your resources by preventing public access from being granted through the resource policies or access control lists (ACLs) that are directly attached to S3 resources. In addition to enabling Block Public Access, carefully inspect the following policies to confirm that they don't grant public access:

- Identity-based policies attached to associated AWS principals (for example, IAM roles)

- Resource-based policies attached to associated AWS resources (for example, AWS Key Management Service (KMS) keys)

Note

- You can enable block public access settings only for organizations, access points, buckets, and AWS accounts. Amazon S3 doesn't support block public access settings on a per-object basis.
- When you apply block public access settings to an account, the settings apply to all AWS Regions globally. The settings might not take effect in all Regions immediately or simultaneously, but they eventually propagate to all Regions.
- When you apply organization-level block public access policies, they automatically propagate to selected member accounts and override account-level settings.

- Configuring block public access settings for your account
- Configuring block public access settings for your S3 buckets

Block public access settings

S3 Block Public Access provides four settings. You can apply these settings in any combination to individual access points, buckets, or entire AWS accounts. At the organization level, you can only enable or disable all four settings together using an "all" or "none" approach - granular control over individual settings is not available. If you apply a setting to an account, it applies to all buckets and

access points that are owned by that account. Account-level settings automatically inherit from organization policies when present. Similarly, if you apply a setting to a bucket, it applies to all access points associated with that bucket.

The policy inheritance and enforcement works as follows:

- Organization-level policies automatically apply to member accounts, enforcing any existing account-level settings
- Account-level setting inherit from organization policies when present, or use locally configured settings when no organization policy exists
- Bucket-level settings operate independently but are subject to enforcement restrictions. S3 applies the most restrictive combination across all applicable levels - organization/account-level and bucket-level settings. This means a bucket inherits the baseline protection from its account (which may be organization-managed), but S3 will enforce whichever configuration is more restrictive between the bucket's settings and the account's effective settings.

The following table contains the available settings.

Name	Description
`BlockPublicAcls`	Setting this option to `TRUE` causes the following behavior: • `PutBucketAcl` and `PutObjectAcl` calls fail if the specified access control list (ACL) is public. • `PutObject` calls fail if the request includes a public ACL. • If this setting is applied to an account, then `PUT Bucket` calls fail if the request includes a public ACL. When this setting is set to `TRUE`, the specified operations fail (whether made through the REST API, AWS CLI, or AWS SDKs). However, existing policies and ACLs for buckets and objects aren't modified. This setting enables you to protect against public access while allowing you to audit, refine, or otherwise alter the existing policies and ACLs for your buckets and objects.

Name	Description
	Note Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled.
`IgnorePublicAcls`	Setting this option to TRUE causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. This setting enables you to safely block public access granted by ACLs while still allowing `PutObject` calls that include a public ACL (as opposed to `BlockPublicAcls`, which rejects `PutObject` calls that include a public ACL). Enabling this setting doesn't affect the persistence of any existing ACLs and doesn't prevent new public ACLs from being set. **Note** Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled.

Name	Description
`BlockPublicPolicy`	Setting this option to TRUE for a bucket causes Amazon S3 to reject calls to `PutBucketPolicy` if the specified bucket policy allows public access. Setting this option to TRUE for a bucket also causes Amazon S3 to reject calls to `PutAccessPointPolicy` for all of the bucket's same-account access points if the specified policy allows public access. Setting this option to TRUE for an access point causes Amazon S3 to reject calls to `PutAccessPointPolicy` and `PutBucketPolicy` that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access. You can use this setting to allow users to manage access point and bucket policies without allowing them to publicly share the bucket or the objects it contains. Enabling this setting doesn't affect existing access point or bucket policies. **Important** To use this setting effectively, we recommend that you apply it at the *account* level. A bucket policy can allow users to alter a bucket's block public access settings. Therefore, users who have permission to change a bucket policy could insert a policy that allows them to disable the block public access settings for the bucket. If this setting is enabled for the entire account, rather than for a specific bucket, Amazon S3 blocks public policies even if a user alters the bucket policy to disable this setting.

Name	Description
RestrictPublicBuckets	Setting this option to TRUE restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket. Enabling this setting doesn't affect existing access point or bucket policies, except that Amazon S3 blocks public and cross-account access derived from any public access point or bucket policy, including non-public delegation to specific accounts.

Important

- Calls to `GetBucketAcl` and `GetObjectAcl` always return the effective permissions in place for the specified bucket or object. For example, suppose that a bucket has an ACL that grants public access, but the bucket also has the `IgnorePublicAcls` setting enabled. In this case, `GetBucketAcl` returns an ACL that reflects the access permissions that Amazon S3 is enforcing, rather than the actual ACL that is associated with the bucket.
- Block public access settings don't alter existing policies or ACLs. Therefore, removing a block public access setting causes a bucket or object with a public policy or ACL to again be publicly accessible.

Managing block public access at organization level

Organization-level block public access uses AWS Organizations policies to centrally manage S3 public access controls across your entire organization. When enabled, these policies automatically apply to selected accounts and override individual account-level settings.

For additional information on block public access at an organization level, see S3 policy in the *AWS Organizations user guide*.

Performing block public access operations on an access point

To perform block public access operations on an access point, use the AWS CLI service `s3control`.

> **Important**
>
> You can't change an access point's block public access settings after creating the access point. You can specify block public access settings for an access point only when creating the access point.

The meaning of "public"

ACLs

Amazon S3 considers a bucket or object ACL public if it grants any permissions to members of the predefined `AllUsers` or `AuthenticatedUsers` groups. For more information about predefined groups, see Amazon S3 predefined groups.

Bucket policies

When evaluating a bucket policy, Amazon S3 begins by assuming that the policy is public. It then evaluates the policy to determine whether it qualifies as non-public. To be considered non-public, a bucket policy must grant access only to fixed values (values that don't contain a wildcard or an AWS Identity and Access Management Policy Variable) for one or more of the following:

- An AWS principal, user, role, or service principal (e.g. `aws:PrincipalOrgID`)
- A set of Classless Inter-Domain Routings (CIDR) blocks, using `aws:SourceIp`. For more information about CIDR, see RFC 4632 on the RFC Editor website.

> **Note**
>
> Bucket policies that grant access conditioned on the `aws:SourceIp` condition key with very broad IP ranges (for example, 0.0.0.0/1) are evaluated as "public." This includes values broader than /8 for IPv4 and /32 for IPv6 (excluding RFC1918 private ranges). Block public access will reject these "public" policies and prevent cross-account access to buckets that are already using these "public" policies.

- `aws:SourceArn`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:SourceOwner`
- `aws:SourceAccount`
- `aws:userid`, outside the pattern "`AROLEID:*`"
- `s3:DataAccessPointArn`

> **Note**
>
> When used in a bucket policy, this value can contain a wildcard for the access point name without rendering the policy public, as long as the account ID is fixed. For example, allowing access to `arn:aws:s3:us-west-2:123456789012:accesspoint/*` would permit access to any access point associated with account `123456789012` in Region `us-west-2`, without rendering the bucket policy public. This behavior is different for access point policies. For more information, see Access points.

- `s3:DataAccessPointAccount`

For more information about bucket policies, see Bucket policies for Amazon S3.

> **Note**
>
> When using multivalued context keys, you must use the `ForAllValues` or `ForAnyValue` set operators.

Example: Public bucket policies

Under these rules, the following example policies are considered public.

```
{
  "Principal": "*",
  "Resource": "*",
  "Action": "s3:PutObject",
  "Effect": "Allow"
 }
```

```
{
  "Principal": "*",
  "Resource": "*",
  "Action": "s3:PutObject",
  "Effect": "Allow",
  "Condition": { "StringLike": {"aws:SourceVpc": "vpc-*"}}
 }
```

You can make these policies non-public by including any of the condition keys listed previously, using a fixed value. For example, you can make the last policy preceding non-public by setting `aws:SourceVpc` to a fixed value, like the following.

```
{
  "Principal": "*",
  "Resource": "*",
  "Action": "s3:PutObject",
  "Effect": "Allow",
  "Condition": {"StringEquals": {"aws:SourceVpc": "vpc-91237329"}}
 }
```

How Amazon S3 evaluates a bucket policy that contains both public and non-public access grants

This example shows how Amazon S3 evaluates a bucket policy that contains both public and non-public access grants.

Suppose that a bucket has a policy that grants access to a set of fixed principals.
Under the previously described rules, this policy isn't public. Thus, if you enable the `RestrictPublicBuckets` setting, the policy remains in effect as written, because `RestrictPublicBuckets` only applies to buckets that have public policies. However, if you add a public statement to the policy, `RestrictPublicBuckets` takes effect on the bucket. It allows only AWS service principals and authorized users of the bucket owner's account to access the bucket.

As an example, suppose that a bucket owned by "Account-1" has a policy that contains the following:

1. A statement that grants access to AWS CloudTrail (which is an AWS service principal)
2. A statement that grants access to account "Account-2"

3. A statement that grants access to the public, for example by specifying `"Principal": "*"` with no limiting `Condition`

This policy qualifies as public because of the third statement. With this policy in place and `RestrictPublicBuckets` enabled, Amazon S3 allows access only by CloudTrail. Even though statement 2 isn't public, Amazon S3 disables access by "Account-2." This is because statement 3 renders the entire policy public, so `RestrictPublicBuckets` applies. As a result, Amazon S3 disables cross-account access, even though the policy delegates access to a specific account, "Account-2." But if you remove statement 3 from the policy, then the policy doesn't qualify as public, and `RestrictPublicBuckets` no longer applies. Thus, "Account-2" regains access to the bucket, even if you leave `RestrictPublicBuckets` enabled.

Access points

Amazon S3 evaluates block public access settings slightly differently for access points compared to buckets. The rules that Amazon S3 applies to determine when an access point policy is public are generally the same for access points as for buckets, except in the following situations:

- An access point that has a VPC network origin is always considered non-public, regardless of the contents of its access point policy.
- An access point policy that grants access to a set of access points using `s3:DataAccessPointArn` is considered public. Note that this behavior is different than for bucket policies. For example, a bucket policy that grants access to values of `s3:DataAccessPointArn` that match `arn:aws:s3:us-west-2:123456789012:accesspoint/*` is not considered public. However, the same statement in an access point policy would render the access point public.

Using IAM Access Analyzer for S3 to review public buckets

You can use IAM Access Analyzer for S3 to review buckets with bucket ACLs, bucket policies, or access point policies that grant public access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single click. You can also drill down into bucket-level permission settings to configure granular levels of access. For

specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket.

In rare cases, IAM Access Analyzer for S3 and Amazon S3 block public access evaluation might differ on whether a bucket is public. This behavior occurs because Amazon S3 block public access performs validation on the existence of actions in addition to evaluating public access. Suppose that the bucket policy contains an `Action` statement that allows public access for an action that isn't supported by Amazon S3 (for example, `s3:NotASupportedAction`). In this case, Amazon S3 block public access evaluates the bucket as public because such a statement could potentially make the bucket public if the action later becomes supported. In cases where Amazon S3 block public access and IAM Access Analyzer for S3 differ in their evaluations, we recommend reviewing the bucket policy and removing any unsupported actions.

For more information about IAM Access Analyzer for S3, see Reviewing bucket access using IAM Access Analyzer for S3.

Permissions

To use Amazon S3 Block Public Access features, you must have the following permissions.

Operation	Required permissions
GET bucket policy status	`s3:GetBucketPolicyStatus`
GET bucket Block Public Access settings	`s3:GetBucketPublicAccessBlock`
PUT bucket Block Public Access settings	`s3:PutBucketPublicAccessBlock`
DELETE bucket Block Public Access settings	`s3:PutBucketPublicAccessBlock`
GET account Block Public Access settings	`s3:GetAccountPublicAccessBlock`
PUT account Block Public Access settings	`s3:PutAccountPublicAccessBlock`
DELETE account Block Public Access settings	`s3:PutAccountPublicAccessBlock`
PUT access point Block Public Access settings	`s3:CreateAccessPoint`

Note

The DELETE operations require the same permissions as the PUT operations. There are no separate permissions for the DELETE operations.

Configuring block public access

For more information about configuring block public access for your AWS account, your Amazon S3 buckets, and your access points, see the following topics:

- Configuring block public access settings for your account
- Configuring block public access settings for your S3 buckets
- Performing block public access operations on an access point

Configuring block public access settings for your account

Important

If your account is managed by an organization-level Block Public Access policy, you cannot modify these account-level settings. Organization-level policies override account-level configurations. For more information on centralized management options, see S3 policy in the *AWS Organizations user guide*.

Amazon S3 Block Public Access provides settings for access points, buckets, organizations, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access. For more information, see Blocking public access to your Amazon S3 storage.

Note

Account level settings override settings on individual objects. Configuring your account to block public access will override any public access settings made to individual objects within your account. When organization-level policies are active, account-level settings automatically inherit from the organization policy and cannot be modified directly.

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to configure block public access settings for all the buckets in your account when not managed by organization policies. For more information, see the sections below.

To configure block public access settings for your buckets, see Configuring block public access settings for your S3 buckets. For information about access points, see Performing block public access operations on an access point.

Using the S3 console

Amazon S3 block public access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit block public access settings for all the S3 buckets in your AWS account. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

To edit block public access settings for all the S3 buckets in an AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Account and organization settings**.
3. Under **Block Public Access settings for this account**:
4. Choose **Edit** to change the block public access settings for all the buckets in your AWS account.
5. Choose the settings that you want to change, and then choose **Save changes**.
6. When you're asked for confirmation, enter **`confirm`**. Then choose **Confirm** to save your changes.

If you receive an error message that says, "This account does not allow changes to its account-level S3 Block Public Access settings due to an organizational S3 Block Public Access policy in effect," your account is managed by organization-level policies. Contact your organization administrator to modify these settings.

Using the AWS CLI

You can use Amazon S3 Block Public Access through the AWS CLI. For more information about setting up and using the AWS CLI, see What is the AWS Command Line Interface?

Account

To perform block public access operations on an account, use the AWS CLI service `s3control`. The account-level operations that use this service are as follows:

- `PutPublicAccessBlock` (for an account)
- `GetPublicAccessBlock` (for an account)
- `DeletePublicAccessBlock` (for an account)

> **Note**
>
> `PutPublicAccessBlock` and `DeletePublicAccessBlock` operations will return an "Access Denied" error when the account is managed by organization-level policies. Account-level `GetPublicAccessBlock` operations will return the enforced organization-level policy if present.

For additional information and examples, see put-public-access-block in the *AWS CLI Reference*.

Using the AWS SDKs

Java

The following examples show you how to use Amazon S3 Block Public Access with the AWS SDK for Java to put a public access block configuration on an Amazon S3 account.

> **Note**
>
> `PutPublicAccessBlock` and `DeletePublicAccessBlock` operations will fail with an "Access Denied" error if the account is managed by organization-level policies.

```
AWSS3ControlClientBuilder controlClientBuilder =
 AWSS3ControlClientBuilder.standard();
controlClientBuilder.setRegion(<region>);
controlClientBuilder.setCredentials(<credentials>);

AWSS3Control client = controlClientBuilder.build();
client.putPublicAccessBlock(new PutPublicAccessBlockRequest()
  .withAccountId(<account-id>)
```

```
  .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
    .withIgnorePublicAcls(<value>)
    .withBlockPublicAcls(<value>)
    .withBlockPublicPolicy(<value>)
    .withRestrictPublicBuckets(<value>)));
```

Important

This example pertains only to account-level operations, which use the `AWSS3Control` client class. For bucket-level operations, see the preceding example.

Other SDKs

For information about using the other AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Account-level operations
  - PutPublicAccessBlock - Fails when account is managed by organization policies
  - GetPublicAccessBlock - Returns effective configuration including organization policies.
  - DeletePublicAccessBlock - Fails when account is managed by organization policies.

You'll see following error message for restricted operations: "This account does not allow changes to its account-level S3 Block Public Access settings due to an organizational S3 Block Public Access policy in effect."

Configuring block public access settings for your S3 buckets

Amazon S3 Block Public Access provides settings for access points, buckets, organizations, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access. For more information, see Blocking public access to your Amazon S3 storage.

> **Note**
>
> Bucket-level Block Public Access settings work alongside organization and account-level policies. S3 applies the most restrictive setting between bucket-level and effective account-level configurations (which may be enforced by organization policies if present).

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to grant public access to one or more buckets. You can also block public access to buckets that are already public. For more information, see the sections below.

To configure block public access settings for every bucket in your account, see Configuring block public access settings for your account. For organization-wide centralized management, see S3 policy in the *AWS Organizations user guide*.

For information about configuring block public access for access points, see Performing block public access operations on an access point.

Using the S3 console

Amazon S3 Block Public Access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit Block Public Access settings for one or more S3 buckets. For information about blocking public access using the AWS CLI, AWS SDKs, and the Amazon S3 REST APIs, see Blocking public access to your Amazon S3 storage.

You can see if your bucket is publicly accessible from the **Buckets** list, in the **IAM Access Analyzer** column. For more information, see Reviewing bucket access using IAM Access Analyzer for S3.

If you see an `Error` when you list your buckets and their public access settings, you might not have the required permissions. Check to make sure you have the following permissions added to your user or role policy:

```
s3:GetAccountPublicAccessBlock
s3:GetBucketPublicAccessBlock
s3:GetBucketPolicyStatus
s3:GetBucketLocation
s3:GetBucketAcl
s3:ListAccessPoints
s3:ListAllMyBuckets
```

In some rare cases, requests can also fail because of an AWS Region outage.

To edit the Amazon S3 block public access settings for a single S3 bucket

Follow these steps if you need to change the public access settings for a single S3 bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Bucket name** list, choose the name of the bucket that you want.
3. Choose **Permissions**.
4. Choose **Edit** next to **Block public access (bucket settings)** to change the public access settings for the bucket. For more information about the four Amazon S3 Block Public Access Settings, see Block public access settings.
5. Choose one of the settings, and then choose **Save changes**.
6. When you're asked for confirmation, enter **`confirm`**. Then choose **Confirm** to save your changes.

> **Important**
>
> Even if you disable bucket-level Block Public Access settings, your bucket may still be protected by account-level or organization-level policies. S3 always applies the most restrictive combination of settings across all levels.

You can also change Amazon S3 Block Public Access settings when you create a bucket. For more information, see Creating a general purpose bucket.

Using the AWS CLI

To block public access on a bucket or to delete the public access block, use the AWS CLI service `s3api`. The bucket-level operations that use this service are as follows:

- `PutPublicAccessBlock` (for a bucket)
- `GetPublicAccessBlock` (for a bucket)
- `DeletePublicAccessBlock` (for a bucket)
- `GetBucketPolicyStatus`

For more information and examples, see put-public-access-block in the *AWS CLI Reference*.

Note

These bucket-level operations are not restricted by organization-level policies. However, the effective public access behavior will still be governed by the most restrictive combination of bucket, account, and organization settings. For more information about the hierarchy and policy interactions, see the section called "Editing bucket public access settings".

Using the AWS SDKs

Java

```
AmazonS3 client = AmazonS3ClientBuilder.standard()
   .withCredentials(<credentials>)
   .build();

client.setPublicAccessBlock(new SetPublicAccessBlockRequest()
  .withBucketName(<bucket-name>)
  .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
    .withBlockPublicAcls(<value>)
    .withIgnorePublicAcls(<value>)
    .withBlockPublicPolicy(<value>)
    .withRestrictPublicBuckets(<value>)));
```

Important

This example pertains only to bucket-level operations, which use the `AmazonS3` client class. For account-level operations, see the following example.

Other SDKs

For information about using the other AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Bucket-level operations
  - PutPublicAccessBlock
  - GetPublicAccessBlock
  - DeletePublicAccessBlock
  - GetBucketPolicyStatus

Granting public access to your Amazon S3 data

Amazon S3 provides multiple ways to grant public access to your data. You can grant public access through a bucket policy, through object tags combined with a bucket policy, or through object access control lists (ACLs). The mechanism you use depends on your goal. For example, to make an entire bucket publicly accessible, you can use a bucket policy. To make only specific objects accessible, you can add a tag to those objects and make them public with a bucket policy.

By default, Amazon S3 blocks public access. New buckets have Block Public Access turned on and have Object Ownership set to Bucket owner enforced, which disables ACLs. Before any object in a bucket can be publicly accessible, you must turn off the Block Public Access settings for the bucket and the account. For more information, see Blocking public access to your Amazon S3 storage.

If you want to grant temporary access to a single object, you can use a presigned URL. A presigned URL gives limited time access to a single object, and you can control how long the URL remains valid by setting its expiration time. For more information, see Sharing objects with presigned URLs.

> **Important**
>
> When you turn off Block Public Access and grant public access, anyone on the internet can access your objects. Grant public access only when a specific use case requires it.

Topics

- Granting public access to an entire bucket
- Granting public access to specific objects with object tags

- Granting public access to an individual object with an ACL

Granting public access to an entire bucket

You can grant public access to an entire bucket with a bucket policy. This is useful when all the objects that you want to make public can be stored together, such as the files for a static website. Store those objects in a bucket that holds only public content, and keep private data in a separate bucket. We recommend this approach because it keeps a clear boundary between public and private data.

To make the objects in a bucket publicly readable, turn off Block Public Access for the bucket and add a bucket policy that grants everyone the `s3:GetObject` permission.

Example

The following bucket policy grants public read access to every object in the bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Granting public access to specific objects with object tags

You can grant public access to specific objects in a bucket by applying an object tag to them and adding a bucket policy that grants read access to any object with that tag. We recommend this approach when you must keep both private and public objects in the same bucket.

With object tags, a single condition in the bucket policy matches every object that has the tag, so one statement can make a large number of objects public. This approach avoids listing individual object keys in the policy, which can contain characters that a policy does not accept and can exceed the bucket policy size limit.

To grant public access to specific objects, turn off Block Public Access for the bucket, apply an object tag such as `public=true` to each object that you want to make public, and add a bucket policy that grants `s3:GetObject` to objects with that tag. For more information about tagging objects, see Tagging your objects.

> **Note**
>
> Object tags incur additional charges, both to apply them and to store them. For more information, see Amazon S3 pricing.

Example

The following bucket policy grants public read access to every object that has the `public=true` tag.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadTaggedObjects",
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:ExistingObjectTag/public": "true"
                }
            }
        }
    ]
}
```

Granting public access to an individual object with an ACL

Object ACLs are a legacy way to grant access, and new buckets disable them by default. We recommend that you keep ACLs disabled, and use Amazon S3 resource-based policies (bucket policies and access point policies) or IAM policies instead, unless you must control access for each object individually. Policies provide simpler and more flexible access control. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> Enabling ACLs applies to the entire bucket, not only the object that you make public. After ACLs are enabled, another account that uploads an object can own it, so you might not control every object in your bucket.

To make an object public with an ACL, turn off Block Public Access for the bucket and enable ACLs by changing the Object Ownership setting from Bucket owner enforced to Bucket owner preferred. Then apply the `public-read` ACL to the object, which grants read access to everyone, so anyone can read the object. For more information, see Managing access with ACLs.

Reviewing bucket access using IAM Access Analyzer for S3

IAM Access Analyzer for S3 provides external access findings for your S3 general purpose buckets that are configured to allow access to anyone on the internet (public) or other AWS accounts, including AWS accounts outside of your organization. For each bucket that's shared publicly or with other AWS accounts, you receive findings into the source and level of shared access. For example, IAM Access Analyzer for S3 might show that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. With these findings, you can take immediate and precise corrective action to restore your bucket access to what you intended.

The Amazon S3 console presents an **External access summary** in the S3 console next to your list of general purpose buckets. In the summary, you can choose the active findings for each AWS Region to see the details of the finding in the IAM Access Analyzer for S3 page. External acces findings in **External access summary** are automatically updated once every 24 hours.

When reviewing a bucket that allows public access, on the IAM Access Analyzer for S3 page, you can block all public access to the bucket with a single click. We recommend that you block all public access to your buckets unless you require public access to support a specific use case. Before you block all public access, ensure that your applications will continue to work correctly without public access. For more information, see Blocking public access to your Amazon S3 storage.

You can also drill down into bucket-level permission settings to configure granular levels of access. For specific and verified use cases that require public access, such as static website hosting, public downloads, or cross-account sharing, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify

these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer. To use IAM Access Analyzer for S3 in the Amazon S3 console, you must visit the IAM console and create an external access analyzer on a per-Region basis.

For more information about IAM Access Analyzer, see What is IAM Access Analyzer? in the *IAM User Guide*. For more information about IAM Access Analyzer for S3, review the following sections.

Important

- IAM Access Analyzer for S3 requires an account-level analyzer in each AWS Region where you have buckets. To use IAM Access Analyzer for S3, you must visit IAM Access Analyzer and create an analyzer that has an account as the zone of trust. For more information, see Enabling IAM Access Analyzer in *IAM User Guide*.
- IAM Access Analyzer for S3 doesn't analyze the access point policy that's attached to cross-account access points. This behavior occurs because the access point and its policy are outside the zone of trust, that is, the account. Buckets that delegate access to a cross-account access point are listed under **Buckets with public access** if you haven't applied the `RestrictPublicBuckets` block public access setting to the bucket or account. When you apply the `RestrictPublicBuckets` block public access setting, the bucket is reported under **Buckets with access from other AWS accounts — including third-party AWS accounts**.
- When a bucket policy or bucket ACL is added or modified, IAM Access Analyzer generates and updates findings based on the change within 30 minutes. Findings related to account level block public access settings might not be generated or updated for up to 6 hours after you change the settings. Findings related to Multi-Region Access Points might not be generated or updated for up to six hours after the Multi-Region Access Point is created, deleted, or you change its policy.

Topics

- Reviewing a global summary of policies that grant external access to buckets
- Information provided by IAM Access Analyzer for S3

- Blocking all public access
- Reviewing and changing bucket access
- Archiving bucket findings
- Activating an archived bucket finding
- Viewing finding details
- Downloading an IAM Access Analyzer for S3 report

Reviewing a global summary of policies that grant external access to buckets

You can use the **External access summary** to view a global summary of policies that grant external access to buckets across your AWS account directly from the S3 console. This summary helps you identify Amazon S3 general purpose buckets in any AWS Region that allow public access or access from other AWS accounts without needing to inspect policies in each AWS Region individually.

Enabling external access summary and IAM Access Analyzer for S3

To use the **External access summary** and IAM Access Analyzer for S3, you must complete the following prerequisite steps.

1. Grant the required permissions. For more information, see Permissions Required to use IAM Access Analyzer in the *IAM User Guide*.
2. Visit IAM to create an account-level analyzer for each Region where you want to use IAM Access Analyzer.

   You can do this by creating an analyzer that has an account as the zone of trust in the IAM console or by using the AWS CLI or AWS SDKs. For more information, see Enabling IAM Access Analyzer in *IAM User Guide*.

Viewing buckets that allow external access

The **External access summary** displays findings and errors for external access that are provided by IAM Access Analyzer for S3 for general purpose buckets. Archived findings and findings for unused access are not included in the summary but can be viewed in the IAM console or IAM Access Analyzer for S3. For more information, see View the IAM Access Analyzer findings dashboard in the IAM User Guide.

> **Note**
>
> The **External access summary** only includes findings for external access analyzers for each of your AWS accounts, not your AWS Organization.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation panel, choose **General purpose buckets**.
3. Expand the **External access summary**. The console displays active public and cross-account access findings.

   > **Note**
   >
   > If S3 experiences an issue loading bucket details, refresh the general purpose buckets list or view findings in IAM Access Analyzer for S3. For more information, see Reviewing bucket access using IAM Access Analyzer for S3.

4. To view a list of findings or errors for an AWS Region, choose the link to the Region. The IAM Access Analyzer for S3 page displays names of buckets that can be accessed publicly or by other AWS accounts. For more information, see Information provided by IAM Access Analyzer for S3.

Updating access controls for buckets that allow external access

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation panel, choose **General purpose buckets**.
3. Expand the **External access summary**. The console displays active findings for buckets that can be accessed publicly or by other AWS accounts.

   > **Note**
   >
   > If S3 experiences an issue loading bucket details, refresh the general purpose buckets list or view findings in IAM Access Analyzer for S3. For more information, see Reviewing bucket access using IAM Access Analyzer for S3.

4. To view a list of findings or errors for an AWS Region, choose the link to the Region. The IAM Access Analyzer for S3 displays active findings for buckets that can be accessed publicly or by other AWS accounts.

   > **Note**
   >
   > External acces findings in **External access summary** are automatically updated once every 24 hours.

5. To block all public access for a bucket, see Blocking all public access. To change the bucket access, see Reviewing and changing bucket access.

Information provided by IAM Access Analyzer for S3

IAM Access Analyzer for S3 provides findings for buckets that can be accessed outside your AWS account. Buckets that are listed under **Public access findings** can be accessed by anyone on the internet. If IAM Access Analyzer for S3 identifies public buckets, you also see a warning banner that shows you the number of public buckets in your Region. Buckets listed under **Cross-account access findings** are shared conditionally with other AWS accounts, including accounts outside of your organization.

For each bucket, IAM Access Analyzer for S3 provides the following information:

- **Bucket name**
- **Shared through** - How the bucket is shared—through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy. Multi-Region Access Points and cross-account access points are reflected under access points. A bucket can be shared through both policies and ACLs. If you want to find and review the source for your bucket access, you can use the information in this column as a starting point for taking immediate and precise corrective action.
- **Status** - The status of the bucket finding. IAM Access Analyzer for S3 displays findings for all public and shared buckets.
  - **Active** - Finding has not been reviewed.
  - **Archived** - Finding has been reviewed and confirmed as intended.
  - **All** - All findings for buckets that are public or shared with other AWS accounts, including AWS accounts outside of your organization.

- **Access level** - Access permissions granted for the bucket:
  - **List** - List resources.
  - **Read** - Read but not edit resource contents and attributes.
  - **Write** - Create, delete, or modify resources.
  - **Permissions** - Grant or modify resource permissions.
  - **Tagging** - Update tags associated with the resource.
- **External principal** - The AWS account outside of your organization with access to the bucket.
- **Resources control policy (RCP) restriction** - The resource control policy (RCP) that applies to the bucket, if applicable. For more information, see Resource control policies (RCPs).

Blocking all public access

If you want to block all access to a bucket in a single click, you can use the **Block all public access** button in IAM Access Analyzer for S3. When you block all public access to a bucket, no public access is granted. We recommend that you block all public access to your buckets unless you require public access to support a specific and verified use case. Before you block all public access, ensure that your applications will continue to work correctly without public access.

If you don't want to block all public access to your bucket, you can edit your block public access settings on the Amazon S3 console to configure granular levels of access to your buckets. For more information, see Blocking public access to your Amazon S3 storage.

In rare cases, IAM Access Analyzer for S3 and Amazon S3 block public access evaluation might differ on whether a bucket is public. This behavior occurs because Amazon S3 block public access performs validation on the existence of actions in addition to evaluating public access. Suppose that the bucket policy contains an `Action` statement that allows public access for an action that isn't supported by Amazon S3 (for example, `s3:NotASupportedAction`). In this case, Amazon S3 block public access evaluates the bucket as public because such a statement could potentially make the bucket public if the action later becomes supported. In cases where Amazon S3 block public access and IAM Access Analyzer for S3 differ in their evaluations, we recommend reviewing the bucket policy and removing any unsupported actions.

To block all public access to a bucket using IAM Access Analyzer for S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation pane on the left, under **Dashboards**, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **Block all public access**.
5. To confirm your intent to block all public access to the bucket, in **Block all public access (bucket settings)**, enter **`confirm`**.

   Amazon S3 blocks all public access to your bucket. The status of the bucket finding updates to **resolved**, and the bucket disappears from the IAM Access Analyzer for S3 listing. If you want to review resolved buckets, open IAM Access Analyzer on the IAM Console.

Reviewing and changing bucket access

If you did not intend to grant access to the public or other AWS accounts, including accounts outside of your organization, you can modify the bucket ACL, bucket policy, the Multi-Region Access Point policy, or the access point policy to remove the access to the bucket. The **Shared through** column shows all sources of bucket access: bucket policy, bucket ACL, and/or access point policy. Multi-Region Access Points and cross-account access points are reflected under access points.

To review and change a bucket policy, a bucket ACL, a Multi-Region Access Point, or an access point policy

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. To see whether public access or shared access is granted through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy, look in the **Shared through** column.
4. Under **Buckets**, choose the name of the bucket with the bucket policy, bucket ACL, Multi-Region Access Point policy, or access point policy that you want to change or review.
5. If you want to change or view a bucket ACL:

   a. Choose **Permissions**.

   b. Choose **Access Control List**.

   c. Review your bucket ACL, and make changes as required.

      For more information, see Configuring ACLs.

6. If you want to change or review a bucket policy:

   a. Choose **Permissions**.

   b. Choose **Bucket Policy**.

   c. Review or change your bucket policy as required.

      For more information, see Adding a bucket policy by using the Amazon S3 console.

7. If you want to change or view a Multi-Region Access Point policy:

   a. Choose **Multi-Region Access Point**.

   b. Choose the Multi-Region Access Point name.

   c. Review or change your Multi-Region Access Point policy as required.

      For more information, see Permissions.

8. If you want to review or change an access point policy:

   a. Choose **Access Points for general purpose buckets** or **Access Points for directory buckets**.

   b. Choose the access point name.

   c. Review or change access as required.

      For more information, see Managing your Amazon S3 access points for general purpose buckets.

   If you edit or remove a bucket ACL, a bucket policy, or an access point policy to remove public or shared access, the status for the bucket findings updates to resolved. The resolved bucket findings disappear from the IAM Access Analyzer for S3 listing, but you can view them in IAM Access Analyzer.

Archiving bucket findings

If a bucket grants access to the public or other AWS accounts, including accounts outside of your organization, to support a specific use case (for example, a static website, public downloads, or cross-account sharing), you can archive the finding for the bucket. When you archive bucket findings, you acknowledge and record your intent for the bucket to remain public or shared.

Archived bucket findings remain in your IAM Access Analyzer for S3 listing so that you always know which buckets are public or shared.

To archive bucket findings in IAM Access Analyzer for S3

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **IAM Access Analyzer for S3**.
3. In IAM Access Analyzer for S3, choose an active bucket.
4. To acknowledge your intent for this bucket to be accessed by the public or other AWS accounts, including accounts outside of your organization, choose **Archive**.
5. Enter **`confirm`**, and choose **Archive**.

Activating an archived bucket finding

After you archive findings, you can always revisit them and change their status back to active, indicating that the bucket requires another review.

To activate an archived bucket finding in IAM Access Analyzer for S3

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. Choose the archived bucket findings.
4. Choose **Mark as active**.

Viewing finding details

If you need to see more information about a finding, you can open the bucket finding details in IAM Access Analyzer on the IAM Console.

To view finding details in IAM Access Analyzer for S3

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **View details**.

The finding details open in IAM Access Analyzer on the IAM Console.

Downloading an IAM Access Analyzer for S3 report

You can download your bucket findings as a CSV report that you can use for auditing purposes. The report includes the same information that you see in IAM Access Analyzer for S3 on the Amazon S3 console.

To download a report

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane on the left, choose **Access analyzer for S3**.
3. In the Region filter, choose the Region.

   IAM Access Analyzer for S3 updates to shows buckets for the chosen Region.
4. Choose **Download report**.

   A CSV report is generated and saved to your computer.

Verifying bucket ownership with bucket owner condition

Amazon S3 bucket owner condition ensures that the buckets you use in your S3 operations belong to the AWS accounts that you expect.

Most S3 operations read from or write to specific S3 buckets. These operations include uploading, copying, and downloading objects, retrieving or modifying bucket configurations, and retrieving or modifying object configurations. When you perform these operations, you specify the bucket that you want to use by including its name with the request. For example, to retrieve an object from S3, you make a request that specifies the name of a bucket and the object key to retrieve from that bucket.

Because Amazon S3 identifies buckets based on their names, an application that uses an incorrect bucket name in a request could inadvertently perform operations against a different bucket than expected. To help avoid unintentional bucket interactions in situations like this, you can use *bucket owner condition*. Bucket owner condition enables you to verify that the target bucket is owned by the expected AWS account, providing an additional layer of assurance that your S3 operations are having the effects you intend.

Topics

- When to use bucket owner condition
- Verifying a bucket owner
- Examples
- Restrictions and limitations

When to use bucket owner condition

We recommend using bucket owner condition whenever you perform a supported S3 operation and know the account ID of the expected bucket owner. Bucket owner condition is available for all S3 object operations and most S3 bucket operations. For a list of S3 operations that don't support bucket owner condition, see Restrictions and limitations.

To see the benefit of using bucket owner condition, consider the following scenario involving AWS customer Bea:

1. Bea develops an application that uses Amazon S3. During development, Bea uses her testing-only AWS account to create a bucket named `bea-data-test`, and configures her application to make requests to `bea-data-test`.
2. Bea deploys her application, but forgets to reconfigure the application to use a bucket in her production AWS account.
3. In production, Bea's application makes requests to `bea-data-test`, which succeed. This results in production data being written to the bucket in Bea's test account.

Bea can help protect against situations like this by using bucket owner condition. With bucket owner condition, Bea can include the AWS account ID of the expected bucket owner in her requests. Amazon S3 then checks the account ID of the bucket owner before processing each request. If the actual bucket owner doesn't match the expected bucket owner, the request fails.

If Bea uses bucket owner condition, the scenario described earlier won't result in Bea's application inadvertently writing to a test bucket. Instead, the requests that her application makes at step 3 will fail with an `Access Denied` error message. By using bucket owner condition, Bea helps eliminate the risk of accidentally interacting with buckets in the wrong AWS account.

Verifying a bucket owner

To use bucket owner condition, you include a parameter with your request that specifies the expected bucket owner. Most S3 operations involve only a single bucket, and require only this single parameter to use bucket owner condition. For `CopyObject` operations, this first parameter specifies the expected owner of the destination bucket, and you include a second parameter to specify the expected owner of the source bucket.

When you make a request that includes a bucket owner condition parameter, S3 checks the account ID of the bucket owner against the specified parameter before processing the request. If the parameter matches the bucket owner's account ID, S3 processes the request. If the parameter doesn't match the bucket owner's account ID, the request fails with an `Access Denied` error message.

You can use bucket owner condition with the AWS Command Line Interface (AWS CLI), AWS SDKs, and Amazon S3 REST APIs. When using bucket owner condition with the AWS CLI and Amazon S3 REST APIs, use the following parameter names.

Access method	Parameter for non-copy operations	Copy operation source parameter	Copy operation destination parameter
AWS CLI	`--expected-bucket-owner`	`--expected-source-bucket-owner`	`--expected-bucket-owner`
Amazon S3 REST APIs	`x-amz-expected-bucket-owner` header	`x-amz-source-expected-bucket-owner` header	`x-amz-expected-bucket-owner` header

The parameter names that are required to use bucket owner condition with the AWS SDKs vary depending on the language. To determine the required parameters, see the SDK documentation for your desired language. You can find the SDK documentation at Tools to Build on AWS.

Examples

The following examples show how you can implement bucket owner condition in Amazon S3 using the AWS CLI or the AWS SDK for Java 2.x.

Example

Example: Upload an object

The following example uploads an object to S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api put-object \
                --bucket amzn-s3-demo-bucket1 --key exampleobject --
body example_file.txt \
                --expected-bucket-owner 111122223333
```

AWS SDK for Java 2.x

```
public void putObjectExample() {
    S3Client s3Client = S3Client.create();;
    PutObjectRequest request = PutObjectRequest.builder()
            .bucket("amzn-s3-demo-bucket1")
            .key("exampleobject")
            .expectedBucketOwner("111122223333")
            .build();
    Path path = Paths.get("example_file.txt");
    s3Client.putObject(request, path);
}
```

Example

Example: Copy an object

The following example copies the object `object1` from S3 bucket *amzn-s3-demo-bucket1* to S3 bucket *amzn-s3-demo-bucket2*. It uses bucket owner condition to ensure that the buckets are owned by the expected accounts according to the following table.

Bucket	Expected owner
amzn-s3-demo-bucket1	111122223333
amzn-s3-demo-bucket2	444455556666

AWS CLI

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket1/object1 \
                            --bucket amzn-s3-demo-bucket2 --key object1copy \
                            --expected-source-bucket-owner 111122223333 --expected-
bucket-owner 444455556666
```

AWS SDK for Java 2.x

```
public void copyObjectExample() {
        S3Client s3Client = S3Client.create();
        CopyObjectRequest request = CopyObjectRequest.builder()
                .copySource("amzn-s3-demo-bucket1/object1")
                .destinationBucket("amzn-s3-demo-bucket2")
                .destinationKey("object1copy")
                .expectedSourceBucketOwner("111122223333")
                .expectedBucketOwner("444455556666")
                .build();
        s3Client.copyObject(request);
    }
```

Example

Example: Retrieve a bucket policy

The following example retrieves the access policy for S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api get-bucket-policy --bucket amzn-s3-demo-bucket1 --expected-bucket-
owner 111122223333
```

AWS SDK for Java 2.x

```
public void getBucketPolicyExample() {
    S3Client s3Client = S3Client.create();
    GetBucketPolicyRequest request = GetBucketPolicyRequest.builder()
            .bucket("amzn-s3-demo-bucket1")
```

```
            .expectedBucketOwner("111122223333")
            .build();
    try {
        GetBucketPolicyResponse response = s3Client.getBucketPolicy(request);
    }
    catch (S3Exception e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    }
}
```

Restrictions and limitations

Amazon S3 bucket owner condition has the following restrictions and limitations:

- The value of the bucket owner condition parameter must be an AWS account ID (12-digit numeric value). Service principals aren't supported.
- Bucket owner condition isn't available for CreateBucket, ListBuckets, or any of the operations included in AWS S3 Control. Amazon S3 ignores any bucket owner condition parameters included with requests to these operations.
- Bucket owner condition only verifies that the account specified in the verification parameter owns the bucket. Bucket owner condition doesn't check the configuration of the bucket. It also doesn't guarantee that the bucket's configuration meets any specific conditions or matches any past state.

Controlling ownership of objects and disabling ACLs for your bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable access control lists (ACLs). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you keep ACLs disabled except in circumstances where you must control access for

each object individually. With ACLs disabled, you can use policies to more easily control access to every object in your bucket, regardless of who uploaded the objects in your bucket.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

For the majority of modern use cases in S3, we recommend that you keep ACLs disabled by applying the Bucket owner enforced setting and using your bucket policy to share data with users outside of your account as needed. This approach simplifies permissions management. You can disable ACLs on both newly created and already existing buckets. For newly created buckets, ACLs are disabled by default. In the case of an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of an access evaluation, and access is granted or denied on the basis of policies. For existing buckets, you can re-enable ACLs at any time after you disable them, and your preexisting bucket and object ACLs are restored.

Before you disable ACLs, we recommend that you review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account. After you disable ACLs, your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs, for example, the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL expressed in XML. Existing applications that support bucket owner full control ACLs see no impact. PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return a `400` error with the error code `AccessControlListNotSupported`.

In contrast, a bucket with the Bucket owner preferred setting continues to accept and honor bucket and object ACLs. With this setting, new objects that are written with the `bucket-owner-full-control` canned ACL are automatically owned by the bucket owner rather than the object writer. All other ACL behaviors remain in place. To require all Amazon S3 PUT operations to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that allows only object uploads using this ACL.

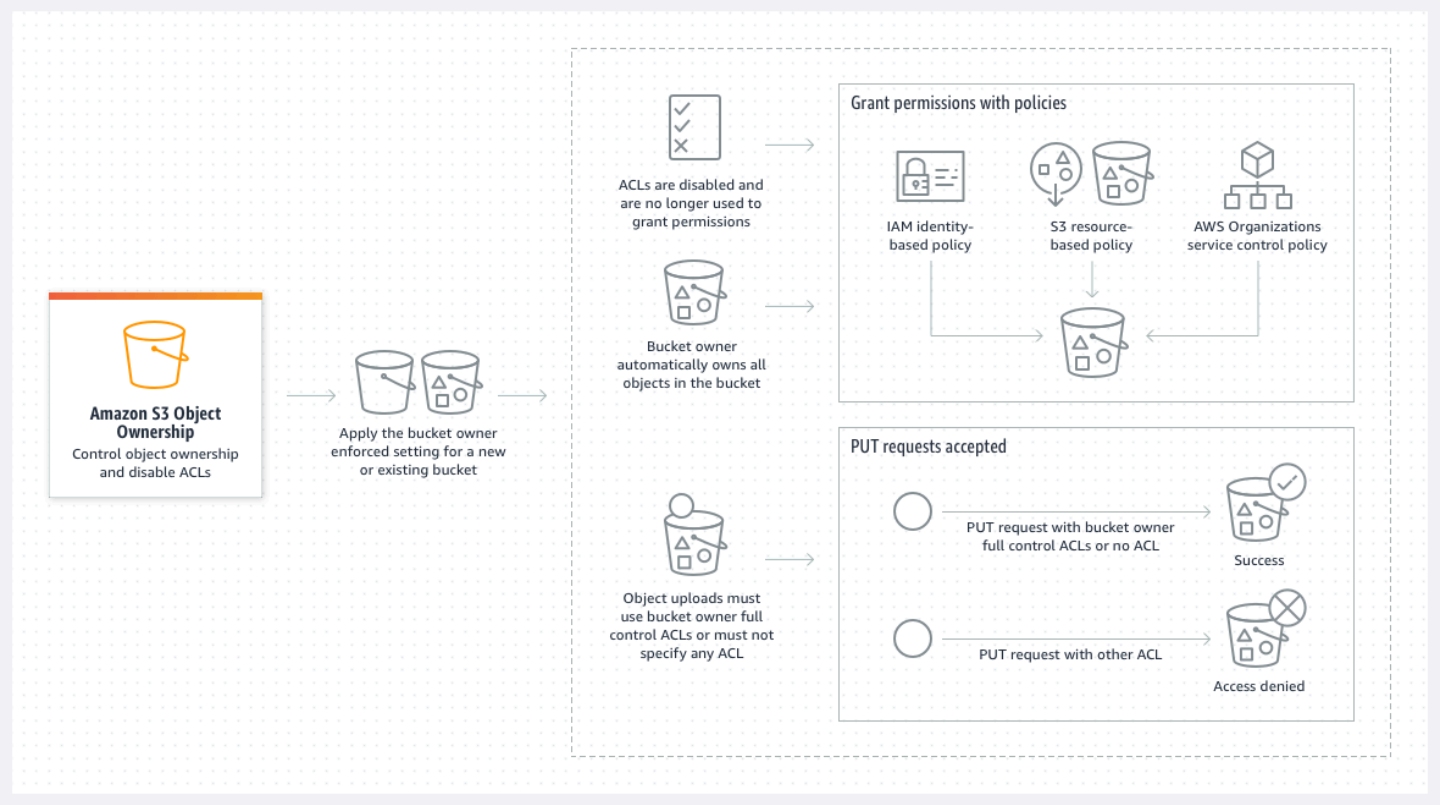
To see which Object Ownership settings are applied to your buckets, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Using S3 Storage Lens to find Object Ownership settings.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

Object Ownership settings

This table shows the impact that each Object Ownership setting has on ACLs, objects, object ownership, and object uploads.

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
Bucket owner enforced (default)	All new and existing objects	Bucket owner owns every object.	ACLs are disabled and no longer affect access permissions to your bucket. Requests to set or update ACLs fail. However, requests to read ACLs are supported.	Uploads with bucket owner full control ACLs or uploads that don't specify an ACL



Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
			Bucket owner has full ownership and control. Object writer no longer has full ownership and control.	
Bucket owner preferred	New objects	If an object upload includes the `bucket-owner-full-control` canned ACL, the bucket owner owns the object. Objects uploaded with other ACLs are owned by the writing account.	ACLs can be updated and can grant permissions. If an object upload includes the `bucket-owner-full-control` canned ACL, the bucket owner has full control access, and the object writer no longer has full control access.	All uploads

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
Object writer	New objects	Object writer owns the object.	ACLs can be updated and can grant permissions. Object writer has full control access.	All uploads

Changes introduced by disabling ACLs

When the Bucket owner enforced setting for Object Ownership is applied, ACLs are disabled and you automatically own and take full control over every object in the bucket without taking any additional actions. Bucket owner enforced is the default setting for all newly created buckets. After the Bucket owner enforced setting is applied, you will see three changes:

- All bucket ACLs and object ACLs are disabled, which gives full access to you, as the bucket owner. When you perform a read ACL request on your bucket or object, you will see that full access is given only to the bucket owner.
- You, as the bucket owner, automatically own and have full control over every object in your bucket.
- ACLs no longer affect access permissions to your bucket. As a result, access control for your data is based on policies, such as AWS Identity and Access Management (IAM) identity-based policies, Amazon S3 bucket policies, VPC endpoint policies, and Organizations service control policies (SCPs) or resource control policies (RCPs).

If you use S3 Versioning, the bucket owner owns and has full control over all object versions in your bucket. Applying the Bucket owner enforced setting does not add a new version of an object.

New objects can be uploaded to your bucket only if they use bucket owner full control ACLs or don't specify an ACL. Object uploads fail if they specify any other ACL. For more information, see Troubleshooting.

Because the following example `PutObject` operation using the AWS Command Line Interface (AWS CLI) includes the `bucket-owner-full-control` canned ACL, the object can be uploaded to a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file --
acl bucket-owner-full-control
```

Because the following `PutObject` operation doesn't specify an ACL, it also succeeds for a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file
```

> **Note**
>
> If other AWS accounts need access to objects after uploading, you must grant additional permissions to those accounts through bucket policies. For more information, see Walkthroughs that use policies to manage access to your Amazon S3 resources.

Re-enabling ACLs

You can re-enable ACLs by changing from the Bucket owner enforced setting to another Object Ownership setting at any time. If you used object ACLs for permissions management before you applied the Bucket owner enforced setting and you didn't migrate these object ACL permissions to your bucket policy, after you re-enable ACLs, these permissions are restored. Additionally, objects written to the bucket while the Bucket owner enforced setting was applied are still owned by the bucket owner.

For example, if you change from the Bucket owner enforced setting back to the Object writer setting, you, as the bucket owner, no longer own and have full control over objects that were previously owned by other AWS accounts. Instead, the uploading accounts again own these objects. Objects owned by other accounts use ACLs for permissions, so you can't use policies to grant permissions to these objects. However, you, as the bucket owner, still own any objects that were written to the bucket while the Bucket owner enforced setting was applied. These objects are not owned by the object writer, even if you re-enable ACLs.

For instructions on enabling and managing ACLs using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs, see Configuring ACLs.

Prerequisites for disabling ACLs

Before you disable ACLs for an existing bucket, complete the following prerequisites.

- Review bucket and object ACLs and migrate ACL permissions
- Identify requests that required an ACL for authorization
- Review and update bucket policies that use ACL-related condition keys

Object Ownership permissions

To apply, update, or delete an Object Ownership setting for a bucket, you need the `s3:PutBucketOwnershipControls` permission. To return the Object Ownership setting for a bucket, you need the `s3:GetBucketOwnershipControls` permission. For more information, see Setting Object Ownership when you create a bucket and Viewing the Object Ownership setting for an S3 bucket.

Disabling ACLs for all new buckets

By default, all new buckets are created with the Bucket owner enforced setting applied and ACLs are disabled. We recommend keeping ACLs disabled. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM policies for access control instead of ACLs. Policies are a simplified and more flexible access control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources.

Replication and Object Ownership

When you use S3 replication and the source and destination buckets are owned by different AWS accounts, you can disable ACLs (with the Bucket owner enforced setting for Object Ownership) to change replica ownership to the AWS account that owns the destination bucket. This setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the Bucket owner enforced setting are owned by the destination bucket owner. For more information about the owner override option for replication configurations, see Changing the replica owner.

Setting Object Ownership

You can apply an Object Ownership setting by using the Amazon S3 console, AWS CLI, AWS SDKs, Amazon S3 REST API, or AWS CloudFormation. The following REST API and AWS CLI commands support Object Ownership:

REST API	AWS CLI	Description
PutBucketOwnershipControls	put-bucket-ownership-controls	Creates or modifies the Object Ownership setting for an existing S3 bucket.
CreateBucket	create-bucket	Creates a bucket using the `x-amz-object-ownership` request header to specify the Object Ownership setting.
GetBucketOwnershipControls	get-bucket-ownership-controls	Retrieves the Object Ownership setting for an Amazon S3 bucket.
DeleteBucketOwnershipControls	delete-bucket-ownership-controls	Deletes the Object Ownership setting for an Amazon S3 bucket.

For more information about applying and working with Object Ownership settings, see the following topics.

Topics

- Prerequisites for disabling ACLs
- Setting Object Ownership when you create a bucket
- Setting Object Ownership on an existing bucket
- Viewing the Object Ownership setting for an S3 bucket
- Disabling ACLs for all new buckets and enforcing Object Ownership
- Troubleshooting

Prerequisites for disabling ACLs

A bucket access control list (ACL) in Amazon S3 is a mechanism that allows you to define granular permissions for individual objects within an S3 bucket, specifying which AWS accounts or groups can access and modify those objects. A majority of modern use cases in Amazon S3 no longer

require the use of ACLs. We recommend that you use AWS Identity and Access Management (IAM) and bucket policies to manage access, and to keep ACLs disabled, except in circumstances where you need to control access for each object individually.

If you have ACLs enabled on your bucket, before you disable ACLs, complete the following prerequisites:

Topics

- Review bucket and object ACLs and migrate ACL permissions
- Identify requests that required an ACL for authorization
- Review and update bucket policies that use ACL-related condition keys
- Example use cases

Review bucket and object ACLs and migrate ACL permissions

When you disable ACLs, permissions granted by bucket and object ACLs no longer affect access. Before you disable ACLs, review your bucket and object ACLs.

Each of your existing bucket and object ACLs has an equivalent in an IAM policy. The following bucket policy examples show you how `READ` and `WRITE` permissions for bucket and object ACLs map to IAM permissions. For more information about how each ACL translates to IAM permissions, see Mapping of ACL permissions and access policy permissions.

Before you disable ACLs:

- If your bucket ACL grants access outside of your AWS account, first, you must migrate your bucket ACL permissions to your bucket policy.
- Next, reset your bucket ACL to the default private ACL.
- We also recommend that you review your object-level ACL permissions and migrate them to your bucket policy.

If your bucket ACLs grant read or write permissions to others outside of your account, before you can disable ACLs, you must migrate these permissions to your bucket policy. After you migrate these permissions, you can set **Object Ownership** to the *Bucket owner enforced* setting. If you don't migrate bucket ACLs that grant read or write access outside of your account, your request to apply the Bucket owner enforced setting fails and returns the InvalidBucketAclWithObjectOwnership error code.

If your bucket ACL grants access outside of your AWS account, before you disable ACLs, you must migrate your bucket ACL permissions to your bucket policy and reset your bucket ACL to the default private ACL. If you don't migrate and reset, your request to apply the Bucket owner enforced setting to disable ACLs fails and returns the InvalidBucketAclWithObjectOwnership error code. We also recommend that you review your object ACL permissions and migrate them to your bucket policy.

To review and migrate ACL permissions to bucket policies, see the following topics.

Topics

- Bucket policies examples
- Using the S3 console to review and migrate ACL permissions
- Using the AWS CLI to review and migrate ACL permissions

Bucket policies examples

These example bucket policies show you how to migrate `READ` and `WRITE` bucket and object ACL permissions for a third-party AWS account to a bucket policy. `READ_ACP` and `WRITE_ACP` ACLs are less relevant for policies because they grant ACL-related permissions (`s3:GetBucketAcl`, `s3:GetObjectAcl`, `s3:PutBucketAcl`, and `s3:PutObjectAcl`).

Example– READ ACL for a bucket

If your bucket had a `READ` ACL that grants AWS account *111122223333* permission to list the contents of your bucket, you can write a bucket policy that grants `s3:ListBucket`, `s3:ListBucketVersions`, `s3:ListBucketMultipartUploads` permissions for your bucket.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
    "Sid": "Permission to list the objects in a bucket",
    "Effect": "Allow",
    "Principal": {
     "AWS": [
```

```
      "arn:aws:iam::111122223333:root"
     ]
    },
    "Action": [
     "s3:ListBucket",
     "s3:ListBucketVersions",
     "s3:ListBucketMultipartUploads"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
   }
  ]
 }
```

Example– READ ACLs for every object in a bucket

If every object in your bucket has a READ ACL that grants access to AWS account *111122223333*, you can write a bucket policy that grants `s3:GetObject` and `s3:GetObjectVersion` permissions to this account for every object in your bucket.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
    "Sid": "Read permission for every object in a bucket",
    "Effect": "Allow",
    "Principal": {
     "AWS": [
      "arn:aws:iam::111122223333:root"
     ]
    },
    "Action": [
     "s3:GetObject",
     "s3:GetObjectVersion"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
   }
  ]
 }
```

This example resource element grants access to a specific object.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

Example– WRITE ACL that grants permissions to write objects to a bucket

If your bucket has a `WRITE` ACL that grants AWS account *111122223333* permission to write objects to your bucket, you can write a bucket policy that grants `s3:PutObject` permission for your bucket.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
   {
    "Sid": "Permission to write objects to a bucket",
    "Effect": "Allow",
    "Principal": {
     "AWS": [
      "arn:aws:iam::111122223333:root"
     ]
    },
    "Action": [
     "s3:PutObject"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
   }
  ]
 }
```

Using the S3 console to review and migrate ACL permissions

To review a bucket's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket name.
3. Choose the **Permissions** tab.

4. Under **Access control list (ACL)**, review your bucket ACL permissions.

To review an object's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket name containing your object.
3. In the **Objects** list, choose your object name.
4. Choose the **Permissions** tab.
5. Under **Access control list (ACL)**, review your object ACL permissions.

To migrate ACL permissions and update your bucket ACL

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket name.
3. On the **Permissions** tab, under **Bucket policy**, choose **Edit**.
4. In the **Policy** box, add or update your bucket policy.

   For example bucket policies, see Bucket policies examples and Example use cases.
5. Choose **Save changes**.
6. Update your bucket ACL to remove ACL grants to other groups or AWS accounts.
7. Apply the **Bucket owner enforced** setting for Object Ownership.

Using the AWS CLI to review and migrate ACL permissions

1. To return the bucket ACL for your bucket, use the get-bucket-acl AWS CLI command:

   ```
   aws s3api get-bucket-acl --bucket amzn-s3-demo-bucket
   ```

   For example, this bucket ACL grants `WRITE` and `READ` access to a third-party account. In this ACL, the third-party account is identified by the canonical user ID. To apply the Bucket owner enforced setting and disable ACLs, you must migrate these permissions for the third-party account to a bucket policy.

```
{
  "Owner": {
   "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
  },
  "Grants": [
   {
    "Grantee": {
     "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
     "Type": "CanonicalUser"
    },
    "Permission": "FULL_CONTROL"
   },
   {
    "Grantee": {
     "ID":
 "72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",
     "Type": "CanonicalUser"
    },
    "Permission": "READ"
   },
   {
    "Grantee": {
     "ID":
 "72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",
     "Type": "CanonicalUser"
    },
    "Permission": "WRITE"
   }
  ]
 }
```

For other example ACLs, see Example use cases.

2. Migrate your bucket ACL permissions to a bucket policy:

   This example bucket policy grants `s3:PutObject` and `s3:ListBucket` permissions for a third-party account. In the bucket policy, the third-party account is identified by the AWS account ID (*111122223333*).

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://
policy.json
```

```
policy.json:
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Sid": "PolicyForCrossAccountAllowUpload",
   "Effect": "Allow",
   "Principal": {
    "AWS": [
     "arn:aws:iam::111122223333:root"
    ]
   },
   "Action": [
    "s3:PutObject",
    "s3:ListBucket"
   ],
   "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket",
    "arn:aws:s3:::amzn-s3-demo-bucket/*"
  }
 ]
}
```

For more example bucket policies, see Bucket policies examples and Example use cases.

3. To return the ACL for a specific object, use the get-object-acl AWS CLI command.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket --key EXAMPLE-OBJECT-KEY
```

4. If required, migrate object ACL permissions to your bucket policy.

   This example resource element grants access to a specific object in a bucket policy.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/EXAMPLE-OBJECT-KEY"
```

5. Reset the ACL for your bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

6. Apply the Bucket owner enforced setting for Object Ownership.

Identify requests that required an ACL for authorization

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. If the request required an ACL for authorization or if you have PUT requests that specify an ACL, the string is `Yes`. If no ACLs were required, or if you are setting a `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is "`-`" in Amazon S3 server access logs and is absent in CloudTrail. For more information about the expected `aclRequired` values, see `aclRequired` values for common Amazon S3 requests.

If you have `PutBucketAcl` or `PutObjectAcl` requests with headers that grant ACL-based permissions, with the exception of the `bucket-owner-full-control` canned ACL, you must remove those headers before you can disable ACLs. Otherwise, your requests will fail.

For all other requests that required an ACL for authorization, migrate those ACL permissions to bucket policies. Then, remove any bucket ACLs before you enable the bucket owner enforced setting.

> **Note**
>
> Do not remove object ACLs. Otherwise, applications that rely on object ACLs for permissions will lose access.

If you see that no requests required an ACL for authorization, you can proceed to disable ACLs. For more information about identifying requests, see Using Amazon S3 server access logs to identify requests and Identifying Amazon S3 requests using CloudTrail.

Review and update bucket policies that use ACL-related condition keys

After you apply the Bucket owner enforced setting to disable ACLs, new objects can be uploaded to your bucket only if the request uses bucket owner full control ACLs or doesn't specify an ACL. Before disabling ACLs, review your bucket policy for ACL-related condition keys.

If your bucket policy uses an ACL-related condition key to require the `bucket-owner-full-control` canned ACL (for example, `s3:x-amz-acl`), you don't need to update your bucket policy. The following bucket policy uses the `s3:x-amz-acl` to require the `bucket-owner-full-control` canned ACL for S3 `PutObject` requests. This policy *still* requires the object writer to

specify the `bucket-owner-full-control` canned ACL. However, buckets with ACLs disabled still accept this ACL, so requests continue to succeed with no client-side changes required.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "OnlyAllowWritesToMyBucketWithBucketOwnerFullControl",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/ExampleUser"
                ]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

However, if your bucket policy uses an ACL-related condition key that requires a different ACL, you must remove this condition key. This example bucket policy requires the `public-read` ACL for S3 `PutObject` requests and therefore must be updated before disabling ACLs.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Only allow writes to my bucket with public read access",
```

```
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/ExampleUser"                ]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "public-read"
                }
            }
        }
    ]
}
```

Example use cases

The following examples show you how to migrate ACL permissions to bucket policies for specific use cases.

Topics

- Grant access to the S3 log delivery group for server access logging
- Grant public read access to the objects in a bucket
- Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

Grant access to the S3 log delivery group for server access logging

If you want to apply the Bucket owner enforced setting to disable ACLs for a server access logging destination bucket (also known as a *target bucket*), you must migrate bucket ACL permissions for the S3 log delivery group to the logging service principal (`logging.s3.amazonaws.com`) in a bucket policy. For more information about log delivery permissions, see Permissions for log delivery.

This bucket ACL grants `WRITE` and `READ_ACP` access to the S3 log delivery group:

```
{
    "Owner": {
```

```
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6Bucket0wnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "Type": "CanonicalUser",
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6Bucket0wnerCanonicalUserID"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
            },
            "Permission": "WRITE"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
            },
            "Permission": "READ_ACP"
        }
    ]
}
```

To migrate bucket ACL permissions for the S3 log delivery group to the logging service principal in a bucket policy

1. Add the following bucket policy to your destination bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://
policy.json

policy.json:      {
    {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3ServerAccessLogsPolicy",
            "Effect": "Allow",
```

```
            "Principal": {
                "Service": "logging.s3.amazonaws.com"
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/EXAMPLE-LOGGING-PREFIX*",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::SOURCE-BUCKET-NAME"
                },
                "StringEquals": {
                    "aws:SourceAccount": "SOURCE-AWS-ACCOUNT-ID"
                }
            }
        }
    ]
}
```

2. Reset the ACL for your destination bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. Apply the Bucket owner enforced setting for Object Ownership to your destination bucket.

Grant public read access to the objects in a bucket

If your object ACLs grant public read access to all of the objects in your bucket, you can migrate these ACL permissions to a bucket policy.

This object ACL grants public read access to an object in a bucket:

```
{
    "Owner": {
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
```

```
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/global/AllUsers"
            },
            "Permission": "READ"
        }
    ]
}
```

To migrate public read ACL permissions to a bucket policy

1. To grant public read access to all of the objects in your bucket, add the following bucket policy, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy
 file://policy.json

policy.json:
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

   To grant public access to a specific object in a bucket policy, use the following format for the `Resource` element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

To grant public access to all of the objects with a specific prefix, use the following format for the `Resource` element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/PREFIX/*"
```

2. Apply the Bucket owner enforced setting for Object Ownership.

Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

You can export your ElastiCache (Redis OSS) backup to an S3 bucket, which gives you access to the backup from outside ElastiCache. To export your backup to an S3 bucket, you must grant ElastiCache permissions to copy a snapshot to the bucket. If you've granted permissions to ElastiCache in a bucket ACL, you must migrate these permissions to a bucket policy before you apply the Bucket owner enforced setting to disable ACLs. For more information, see Grant ElastiCache access to your Amazon S3 bucket in the *Amazon ElastiCache User Guide*.

The following example shows the bucket ACL permissions that grant permissions to ElastiCache.

```
{
    "Owner": {
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "ID":
 "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "READ"
```

```
        },
        {
            "Grantee": {
                "ID":
 "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "WRITE"
        },
        {
            "Grantee": {
                "ID":
 "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
                "Type": "CanonicalUser"
            },
            "Permission": "READ_ACP"
        }
    ]
}
```

To migrate bucket ACL permissions for ElastiCache (Redis OSS) to a bucket policy

1. Add the following bucket policy to your bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy
 file://policy.json

policy.json:
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Stmt15399483",
            "Effect": "Allow",
            "Principal": {
                "Service": "Region.elasticache-snapshot.amazonaws.com"
            },
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3:ListBucket",
                "s3:GetBucketAcl",
                "s3:ListMultipartUploadParts",
```

```
                "s3:ListBucketMultipartUploads"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

2. Reset the ACL for your bucket to the default ACL:

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. Apply the Bucket owner enforced setting for Object Ownership.

Setting Object Ownership when you create a bucket

When you create a bucket, you can configure S3 Object Ownership. To set Object Ownership for an existing bucket, see Setting Object Ownership on an existing bucket.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable access control lists (ACLs) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Permissions: To apply the **Bucket owner enforced** setting or the **Bucket owner preferred** setting, you must have the following permissions: `s3:CreateBucket` and `s3:PutBucketOwnershipControls`. No additional permissions are needed when creating a bucket with the **Object writer** setting applied. For more information about Amazon S3 permissions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

> **Important**
>
> A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you disable ACLs except in circumstances where you need to control access for each object individually. With Object Ownership, you can disable ACLs and rely on policies for access control. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts. You, as the bucket owner, own all the objects in the bucket and can manage access to them using policies.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

> **Note**
>
> - After you create a bucket, you can't change its Region.

- To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket.

   The bucket name must:

   - Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (commercial Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US) Regions).
   - Be between 3 and 63 characters long.
   - Consist only of lowercase letters, numbers, periods (`.`), and hyphens (`-`). For best compatibility, we recommend that you avoid using periods (`.`) in bucket names, except for buckets that are used only for static website hosting.
   - Begin and end with a letter or number.
   - For a complete list of bucket-naming rules, see General purpose bucket naming rules.

   Important

   - After you create the bucket, you can't change its name.
   - Don't include sensitive information in the bucket name. The bucket name is visible in the URLs that point to the objects in the bucket.

6. (Optional) Under **General configuration**, you can choose to copy an existing bucket's settings to your new bucket. If you don't want to copy the settings of an existing bucket, skip to the next step.

   Note

   This option:

   - Isn't available in the AWS CLI and is only available in the Amazon S3 console

- Doesn't copy the bucket policy from the existing bucket to the new bucket

To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you want to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window reopens.

Under **Copy settings from existing bucket**, you now see the name of the bucket that you selected. The settings of your new bucket now match the settings of the bucket that you selected. If you want to remove the copied settings, choose **Restore defaults**. Review the remaining bucket settings on the **Create bucket** page. If you don't want to make any changes, you can skip to the final step.

7. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the general purpose bucket. ACLs no longer affect access permissions to data in the S3 general purpose bucket. The bucket uses policies exclusively to define access control.

  By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you must control access for each object individually. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

  If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that allows only object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

> **Note**
>
> The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

8. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

   By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.

   > **Note**
   >
   > To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

9. (Optional) By default, **Bucket Versioning** is disabled. Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can recover more easily from both unintended user actions and application failures. For more information about versioning, see Retaining multiple versions of objects with S3 Versioning.

   To enable versioning on your bucket, choose **Enable**.

10. (Optional) Under **Tags**, you can choose to add tags to your bucket. With AWS cost allocation, you can use bucket tags to annotate billing for your use of a bucket. A tag is a key-value pair that represents a label that you assign to a bucket. For more information, see the section called “Using cost allocation tags”.

    To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

11. To configure **Default encryption**, under **Encryption type**, choose one of the following:

- **Server-side encryption with Amazon S3 managed keys (SSE-S3)**
- **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
- **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**

> **Important**
>
> If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

Buckets and new objects are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption configuration. For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets. For more information about SSE-S3, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

For more information about using server-side encryption to encrypt your data, see the section called "Data encryption".

12. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)**, do the following:

    a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

    - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

      Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

    - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.

- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that isn't listed, you must enter your KMS key ARN. If you want to use a KMS key that's owned by a different account, you must first have permission to use the key, and then you must enter the KMS key ARN. For more information about cross account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*. For more information about SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS). For more information about DSSE-KMS, see the section called "Dual-layer server-side encryption (DSSE-KMS)". When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

b. When you configure your bucket to use default encryption with SSE-KMS, you can also use S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys. S3 Bucket Keys aren't supported for DSSE-KMS.

   By default, S3 Bucket Keys are enabled in the Amazon S3 console. We recommend leaving S3 Bucket Keys enabled to lower your costs. To disable S3 Bucket Keys for your bucket, under **Bucket Key**, choose **Disable**.

13. (Optional) S3 Object Lock helps protect new objects from being deleted or overwritten. For more information, see Locking objects with Object Lock. If you want to enable S3 Object Lock, do the following:

    a. Choose **Advanced settings**.

> **Important**
>
> Enabling Object Lock automatically enables versioning for the bucket. After you've enabled and successfully created the bucket, you must also configure the Object Lock default retention and legal hold settings on the bucket's **Properties** tab.

b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

> **Note**
>
> To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning`, and `s3:PutBucketObjectLockConfiguration`.

14. Choose **Create bucket**.

Using the AWS CLI

To set Object Ownership when you create a new bucket, use the `create-bucket` AWS CLI command with the `--object-ownership` parameter.

This example applies the Bucket owner enforced setting for a new bucket using the AWS CLI:

```
aws s3api create-bucket --bucket  amzn-s3-demo-bucket --region us-east-1 --object-
ownership BucketOwnerEnforced
```

> **Important**
>
> If you don't set Object Ownership when you create a bucket by using the AWS CLI, the default setting will be `ObjectWriter` (ACLs enabled).

Using the AWS SDK for Java

This example sets the Bucket owner enforced setting for a new bucket using the AWS SDK for Java:

```
    // Build the ObjectOwnership for CreateBucket
```

```
    CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
            .bucket(bucketName)
            .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
            .build()

     // Send the request to Amazon S3
     s3client.createBucket(createBucketRequest);
```

Using CloudFormation

To use the `AWS::S3::Bucket` CloudFormation resource to set Object Ownership when you create a new bucket, see OwnershipControls within AWS::S3::Bucket in the *AWS CloudFormation User Guide*.

Using the REST API

To apply the Bucket owner enforced setting for S3 Object Ownership, use the `CreateBucket` API operation with the `x-amz-object-ownership` request header set to `BucketOwnerEnforced`. For information and examples, see CreateBucket in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- Bucket owner enforced – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- Bucket owner preferred – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Setting Object Ownership on an existing bucket

You can configure S3 Object Ownership on an existing S3 bucket. To apply Object Ownership when you create a bucket, see Setting Object Ownership when you create a bucket.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable access control lists (ACLs) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using

access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Prerequisites: Before you apply the Bucket owner enforced setting to disable ACLs, you must migrate bucket ACL permissions to bucket policies and reset your bucket ACLs to the default private ACL. We also recommend that you migrate object ACL permissions to bucket policies and edit bucket policies that require ACLs other than bucket owner full control ACLs. For more information, see Prerequisites for disabling ACLs.

Permissions: To use this operation, you must have the `s3:PutBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an S3 Object Ownership setting to.

3. Choose the **Permissions** tab.
4. Under **Object Ownership**, choose **Edit**.
5. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

   ACLs disabled

   - **Bucket owner enforced** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

     To require that all new buckets are created with ACLs disabled by using IAM or AWS Organizations policies, see Disabling ACLs for all new buckets (bucket owner enforced).

   ACLs enabled

   - **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

     If you apply the bucket owner preferred setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can add a bucket policy that only allows object uploads that use this ACL.
   - **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.
6. Choose **Save**.

Using the AWS CLI

To apply an Object Ownership setting for an existing bucket, use the `put-bucket-ownership-controls` command with the `--ownership-controls` parameter. Valid values for ownership are `BucketOwnerEnforced`, `BucketOwnerPreferred`, or `ObjectWriter`.

This example applies the Bucket owner enforced setting for an existing bucket by using the AWS CLI:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-
controls="Rules=[{ObjectOwnership=BucketOwnerEnforced}]"
```

For information about `put-bucket-ownership-controls`, see put-bucket-ownership-controls in the *AWS Command Line Interface User Guide*.

Using the AWS SDK for Java

This example applies the `BucketOwnerEnforced` setting for Object Ownership on an existing bucket by using the AWS SDK for Java:

```
        // Build the ObjectOwnership for BucketOwnerEnforced
        OwnershipControlsRule rule = OwnershipControlsRule.builder()
               .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
               .build();

        OwnershipControls ownershipControls = OwnershipControls.builder()
                  .rules(rule)
                  .build()

         // Build the PutBucketOwnershipControlsRequest
         PutBucketOwnershipControlsRequest putBucketOwnershipControlsRequest =
               PutBucketOwnershipControlsRequest.builder()
                       .bucket(BUCKET_NAME)
                       .ownershipControls(ownershipControls)
                       .build();

         // Send the request to Amazon S3
         s3client.putBucketOwnershipControls(putBucketOwnershipControlsRequest);
```

Using CloudFormation

To use CloudFormation to apply an Object Ownership setting for an existing bucket, see AWS::S3::Bucket OwnershipControls in the *AWS CloudFormation User Guide*.

Using the REST API

To use the REST API to apply an Object Ownership setting to an existing S3 bucket, use `PutBucketOwnershipControls`. For more information, see PutBucketOwnershipControls in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- Bucket owner enforced – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.

- Bucket owner preferred – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Viewing the Object Ownership setting for an S3 bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable access control lists (ACLs) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

You can view the S3 Object Ownership settings for an Amazon S3 bucket. To set Object Ownership for a new bucket, see Setting Object Ownership when you create a bucket. To set Object Ownership for an existing bucket, see Setting Object Ownership on an existing bucket.

Permissions: To use this operation, you must have the `s3:GetBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an Object Ownership setting to.
3. Choose the **Permissions** tab.
4. Under **Object Ownership**, you can view the Object Ownership settings for your bucket.

Using the AWS CLI

To retrieve the S3 Object Ownership setting for an S3 bucket, use the get-bucket-ownership-controls AWS CLI command.

```
aws s3api get-bucket-ownership-controls --bucket amzn-s3-demo-bucket
```

Using the REST API

To retrieve the Object Ownership setting for an S3 bucket, use the `GetBucketOwnershipControls` API operation. For more information, see GetBucketOwnershipControls.

Disabling ACLs for all new buckets and enforcing Object Ownership

We recommend that you disable ACLs on your Amazon S3 buckets. You can do this by applying the Bucket owner enforced setting for S3 Object Ownership. When you apply this setting, ACLs are disabled and you automatically own and have full control over all objects in your bucket. To require that all new buckets are created with ACLs disabled, use AWS Identity and Access Management (IAM) policies or AWS Organizations service control policies (SCPs), as described in the next section.

To enforce object ownership for new objects without disabling ACLs, you can apply the Bucket owner preferred setting. When you apply this setting, we strongly recommend that you update your bucket policy to require the `bucket-owner-full-control` canned ACL for all PUT requests to your bucket. Make sure you also update your clients to send the `bucket-owner-full-control` canned ACL to your bucket from other accounts.

Topics

- Disabling ACLs for all new buckets (bucket owner enforced)
- Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations (bucket owner preferred)

Disabling ACLs for all new buckets (bucket owner enforced)

The following example IAM policy denies the `s3:CreateBucket` permission for a specific IAM user or role unless the Bucket owner enforced setting is applied for Object Ownership. The key-value pair in the `Condition` block specifies `s3:x-amz-object-ownership` as its key and the `BucketOwnerEnforced` setting as its value. In other words, the IAM user can create buckets only if they set the Bucket owner enforced setting for Object Ownership and disable ACLs. You can also use this policy as a boundary SCP for your AWS organization.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RequireBucketOwnerFullControl",
            "Action": "s3:CreateBucket",
            "Effect": "Deny",
            "Resource": "*",
            "Condition": {
                "StringNotEquals": {
                    "s3:x-amz-object-ownership": "BucketOwnerEnforced"
                }
            }
        }
    ]
}
```

Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations (bucket owner preferred)

With the Bucket owner preferred setting for Object Ownership, you, as the bucket owner, own and have full control over new objects that other accounts write to your bucket with the `bucket-`

owner-full-control canned ACL. However, if other accounts write objects to your bucket without the bucket-owner-full-control canned ACL, the object writer maintains full control access. You, as the bucket owner, can implement a bucket policy that allows writes only if they specify the bucket-owner-full-control canned ACL.

> **Note**
>
> If you have ACLs disabled with the Bucket owner enforced setting, you, as the bucket owner, automatically own and have full control over all the objects in your bucket. You don't need to use this section to update your bucket policy to enforce object ownership for the bucket owner.

The following bucket policy specifies that account *111122223333* can upload objects to *amzn-s3-demo-bucket* only when the object's ACL is set to bucket-owner-full-control. Be sure to replace *111122223333* with your account and *amzn-s3-demo-bucket* with the name of your bucket.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "OnlyAllowWritesToMyBucketWithBucketOwnerFullControl",
         "Effect": "Allow",
         "Principal": {
            "AWS": [
               "arn:aws:iam::111122223333:user/ExampleUser"
            ]
         },
         "Action": [
            "s3:PutObject"
         ],
         "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
         "Condition": {
            "StringEquals": {
               "s3:x-amz-acl": "bucket-owner-full-control"
            }
         }
```

```
        }
    ]
}
```

The following is an example copy operation that includes the `bucket-owner-full-control` canned ACL by using the AWS Command Line Interface (AWS CLI).

```
aws s3 cp file.txt s3://amzn-s3-demo-bucket --acl bucket-owner-full-control
```

After the bucket policy is put into effect, if the client does not include the `bucket-owner-full-control` canned ACL, the operation fails, and the uploader receives the following error:

An error occurred (AccessDenied) when calling the PutObject operation: Access Denied.

> **Note**
>
> If clients need access to objects after uploading, you must grant additional permissions to the uploading account. For information about granting accounts access to your resources, see Walkthroughs that use policies to manage access to your Amazon S3 resources.

Troubleshooting

When you apply the Bucket owner enforced setting for S3 Object Ownership, access control lists (ACLs) are disabled and you, as the bucket owner, automatically own all objects in your bucket. ACLs no longer affect permissions for the objects in your bucket. You can use policies to grant permissions. All S3 PUT requests must either specify the `bucket-owner-full-control` canned ACL or not specify an ACL, or these requests will fail. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

If an invalid ACL is specified or bucket ACL permissions grant access outside of your AWS account, you might see the following error responses.

AccessControlListNotSupported

After you apply the Bucket owner enforced setting for Object Ownership, ACLs are disabled. Requests to set ACLs or update ACLs fail with a `400` error and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported. Requests

to read ACLs always return a response that shows full control for the bucket owner. In your PUT operations, you must either specify bucket owner full control ACLs or not specify an ACL. Otherwise, your PUT operations fail.

The following example `put-object` AWS CLI command includes the `public-read` canned ACL.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object-key-name --body doc-example-body --acl public-read
```

If the bucket uses the Bucket owner enforced setting to disable ACLs, this operation fails, and the uploader receives the following error message:

An error occurred (AccessControlListNotSupported) when calling the PutObject operation: The bucket does not allow ACLs

InvalidBucketAclWithObjectOwnership

If you want to apply the Bucket owner enforced setting to disable ACLs, your bucket ACL must give full control only to the bucket owner. Your bucket ACL cannot give access to an external AWS account or any other group. For example, if your `CreateBucket` request sets Bucket owner enforced and specifies a bucket ACL that provides access to an external AWS account, your request fails with a `400` error and returns the InvalidBucketAclWithObjectOwnership error code. Similarly, if your `PutBucketOwnershipControls` request sets Bucket owner enforced on a bucket that has a bucket ACL that grants permissions to others, the request fails.

Example: Existing bucket ACL grants public read access

For example, if an existing bucket ACL grants public read access, you cannot apply the Bucket owner enforced setting for Object Ownership until you migrate these ACL permissions to a bucket policy and reset your bucket ACL to the default private ACL. For more information, see Prerequisites for disabling ACLs.

This example bucket ACL grants public read access:

```
{
    "Owner": {
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
```

```
        {
            "Grantee": {
                "ID":
 "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "Type": "Group",
                "URI": "http://acs.amazonaws.com/groups/global/AllUsers"
            },
            "Permission": "READ"
        }
    ]
}
```

The following example `put-bucket-ownership-controls` AWS CLI command applies the Bucket owner enforced setting for Object Ownership:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-
controls Rules=[{ObjectOwnership=BucketOwnerEnforced}]
```

Because the bucket ACL grants public read access, the request fails and returns the following error code:

An error occurred (InvalidBucketAclWithObjectOwnership) when calling the PutBucketOwnershipControls operation: Bucket cannot have ACLs set with ObjectOwnership's BucketOwnerEnforced setting

Security in Amazon S3

Important

Amazon Simple Storage Service now applies a new default bucket security setting that automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. In April 2026, Amazon S3 deployed an update so all new general purpose buckets have SSE-C encryption disabled for all new write requests. For existing buckets in AWS accounts with no SSE-C encrypted objects, Amazon S3 also disabled SSE-C for all new write requests. With this change, applications that need SSE-C encryption must deliberately enable SSE-C by using the PutBucketEncryption API operation after creating a new bucket. For more information about this change, see Default SSE-C setting for new buckets FAQ.

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

Security of the cloud

AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon S3, see AWS Services in Scope by Compliance Program.

Security in the cloud

Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations. For Amazon S3, your responsibility includes the following areas:

- Managing your data, including object ownership and encryption.
- Classifying your assets.

- Managing access to your data using IAM roles and other service configurations to apply the appropriate permissions.
- Enabling detective controls such as AWS CloudTrail or Amazon GuardDuty for Amazon S3.

This documentation will help you understand how to apply the shared responsibility model when using Amazon S3. The following topics show you how to configure Amazon S3 to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you monitor and secure your Amazon S3 resources.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

Security best practices for Amazon S3

> **Important**
>
> Amazon Simple Storage Service now applies a new default bucket security setting that automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. In April 2026, Amazon S3 deployed an update so all new general purpose buckets have SSE-C encryption disabled for all new write requests. For existing buckets in AWS accounts with no SSE-C encrypted objects, Amazon S3 also disabled SSE-C for all new write requests. With this change, applications that need SSE-C encryption must deliberately enable SSE-C by using the PutBucketEncryption API operation after creating a new bucket. For more information about this change, see Default SSE-C setting for new buckets FAQ.

Amazon S3 provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful recommendations rather than prescriptions.

Topics

- Amazon S3 security best practices
- Amazon S3 monitoring and auditing best practices
- Monitoring data security with managed AWS security services

Amazon S3 security best practices

The following best practices for Amazon S3 can help prevent security incidents.

Disable access control lists (ACLs)

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of access control lists (ACLs). We recommend that you disable ACLs, except in circumstances where you must control access for each object individually. To disable ACLs and take ownership of every object in your bucket, apply the bucket owner enforced setting for S3 Object Ownership. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts.

When ACLs are disabled access control for your data is based on policies, such as the following:

- AWS Identity and Access Management (IAM) user policies
- S3 bucket policies
- Virtual private cloud (VPC) endpoint policies
- AWS Organizations service control policies (SCPs)
- AWS Organizations resource control policies (RCPs)

Disabling ACLs simplifies permissions management and auditing. ACLs are disabled for new buckets by default. You can also disable ACLs for existing buckets. If you have an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of the access-evaluation process. Instead, access is granted or denied on the basis of policies.

Before you disable ACLs, make sure that you do the following:

- Review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account.
- Reset your bucket ACL to the default (full control to the bucket owner).

After you disable ACLs, the following behaviors occur:

- Your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs. These ACLs include the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL that are expressed in XML.
- Existing applications that support bucket owner full control ACLs see no impact.
- PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return an HTTP status code `400 (Bad Request)` with the error code `AccessControlListNotSupported`.

For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

Ensure that your Amazon S3 buckets use the correct policies and are not publicly accessible

Unless you explicitly require anyone on the internet to be able to read or write to your S3 bucket, make sure that your S3 bucket is not public. The following are some of the steps that you can take to block public access:

- Use S3 Block Public Access. With S3 Block Public Access, you can easily set up centralized controls to limit public access to your Amazon S3 resources. These centralized controls are enforced regardless of how the resources are created. For organizations managing multiple AWS accounts, you can now use organization-level enforcement through AWS Organizations to centrally manage S3 Block Public Access settings across your entire organization with a single policy configuration.

  For more information, see Blocking public access to your Amazon S3 storage.
- Identify Amazon S3 bucket policies that allow a wildcard identity such as `"Principal": "*"` (which effectively means "anyone"). Also look for policies that allow a wildcard action `"*"` (which effectively allows the user to perform any action in the Amazon S3 bucket).
- Similarly, look for Amazon S3 bucket access control lists (ACLs) that provide read, write, or full-access to "Everyone" or "Any authenticated AWS user."
- Use the `ListBuckets` API operation to scan all of your Amazon S3 buckets. Then use `GetBucketAcl`, `GetBucketWebsite`, and `GetBucketPolicy` to determine whether each bucket has compliant access controls and a compliant configuration.
- Use AWS Trusted Advisor to inspect your Amazon S3 implementation.
- Consider implementing ongoing detective controls by using the s3-bucket-public-read-prohibited and s3-bucket-public-write-prohibited managed AWS Config Rules.

For organizations with multiple AWS accounts, consider using organization-level Block Public Access management:

- Centralized policy management: Use AWS Organizations to create a single S3 Block Public Access policy that automatically applies to all member accounts or selected organizational units (OUs).
- Automatic inheritance: When you attach the policy at the root or OU level, new member accounts automatically inherit the Block Public Access settings without individual account setup.
- Simplified compliance: Organization-level policies eliminate the need to maintain complex Service Control Policies (SCPs) for Block Public Access enforcement and reduce operational overhead of managing individual account configurations.

- Audit capabilities: Use AWS CloudTrail to monitor policy attachment and enforcement across member accounts for compliance tracking.

For more information, see Identity and Access Management for Amazon S3.

Keep server-side encryption with customer-provided keys (SSE-C) disabled unless your workload requires it

Starting April 2026, Amazon S3 automatically disables SSE-C for all new general purpose buckets and existing buckets in accounts with no SSE-C encrypted objects. We recommend keeping SSE-C disabled unless your workload has a specific requirement for this encryption offering.

SSE-C requires you to provide the encryption key with every request to read or write encrypted objects. This makes it impractical to share access with other users, roles, or AWS services that operate on your data. Objects encrypted with SSE-C cannot be natively decrypted by AWS managed services. For most workloads, server-side encryption with Amazon S3 managed keys (SSE-S3) or AWS KMS keys (SSE-KMS) provides equivalent protection with greater flexibility.

If you have existing buckets where SSE-C is still enabled, review whether it's still needed and block it if not. When SSE-C is blocked, any `PutObject`, `CopyObject`, `PostObject`, Multipart Upload, or replication request that specifies SSE-C encryption is rejected with an HTTP 403 `AccessDenied` error.

To learn more about blocking SSE-C, see the section called “Blocking or unblocking SSE-C”.

Create buckets in your account regional namespace

By default, you create global general purpose buckets in the shared global namespace. After creating a general purpose bucket in the shared global namespace, that bucket name is unavailable for anyone else to create within partition. When you delete a global general purpose bucket, the bucket name becomes available again in the global namespace for anyone to re-create.

Although Amazon S3 general purpose buckets exist in a shared global namespace, you can optionally create buckets in your account regional namespace. The account regional namespace is a reserved subdivision of the global bucket namespace where only your account can create general purpose buckets. We recommend you create buckets in your account regional namespace since these buckets are unique to your account and can never be re-created by another account. For more information, see Namespaces for general purpose buckets.

We recommend that you don't delete your global general purpose buckets in the shared global namespace. All AWS Accounts now have a default bucket quota of 10,000 buckets, reducing the need to delete empty buckets from your account. If you delete a bucket in the shared global namespace, be aware that another AWS account in the same partition can use the same bucket name for a new bucket and can therefore potentially receive requests that are intended for the deleted bucket. If you want to prevent this, or if you want to continue to use the same bucket name, don't delete the bucket. We recommend that you empty the bucket and keep it. Instead of deleting the bucket, block any bucket requests as needed. For buckets no longer in active use, we recommend emptying the bucket of all objects to minimize costs while retaining the bucket itself. For more information, see Deleting a general purpose bucket.

Implement least privilege access

When granting permissions, you decide who is getting what permissions to which Amazon S3 resources. You enable specific actions that you want to allow on those resources. Therefore, we recommend that you grant only the permissions that are required to perform a task. Implementing least privilege access is fundamental in reducing security risk and the impact that could result from errors or malicious intent.

The following tools are available to implement least privilege access:

- Policy actions for Amazon S3 and Permissions Boundaries for IAM Entities
- How Amazon S3 works with IAM
- Access control list (ACL) overview

For guidance on what to consider when choosing one or more of the preceding mechanisms, see Identity and Access Management for Amazon S3.

Use IAM roles for applications and AWS services that require Amazon S3 access

In order for applications running on Amazon EC2 or other AWS services to access Amazon S3 resources, they must include valid AWS credentials in their AWS API requests. We recommend not storing AWS credentials directly in the application or Amazon EC2 instance. These are long-term credentials that are not automatically rotated and could have a significant business impact if they are compromised.

Instead, use an IAM role to manage temporary credentials for applications or services that need to access Amazon S3. When you use a role, you don't have to distribute long-term credentials (such as a username and password or access keys) to an Amazon EC2 instance or AWS service, such as AWS Lambda. The role supplies temporary permissions that applications can use when they make calls to other AWS resources.

For more information, see the following topics in the *IAM User Guide*:

- IAM Roles
- Common Scenarios for Roles: Users, Applications, and Services

Consider encryption of data at rest

You have the following options for protecting data at rest in Amazon S3:

- **Server-side encryption** – All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

  Amazon S3 also provides these server-side encryption options:

  - Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
  - Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)
  - Server-side encryption with customer-provided keys (SSE-C)

  For more information, see Protecting data with server-side encryption.
- **Client-side encryption** – Encrypt data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, the encryption keys, and related tools. As with server-side encryption, client-side encryption can help reduce risk by encrypting the data with a key that is stored in a different mechanism than the mechanism that stores the data itself.

  Amazon S3 provides multiple client-side encryption options. For more information, see Protecting data by using client-side encryption.

Enforce encryption of data in transit

You can use HTTPS (TLS) to help prevent potential attackers from eavesdropping on or manipulating network traffic by using person-in-the-middle or similar attacks. We recommend allowing only encrypted connections over HTTPS (TLS) by using the aws:SecureTransport condition in your Amazon S3 bucket policies. For more information, see the example S3 bucket policy Managing access based on HTTP or HTTPS requests. In addition to denying HTTP requests, we recommend that you set Amazon CloudWatch alarms on

`tlsDetails.tlsVersion NOT EXISTS` that alert you if HTTP access attempts are made on your content. For more information on how to configure Amazon CloudWatch alarms, see Creating CloudWatch alarms for CloudTrail events: examples and CloudTrail record contents in the *AWS CloudTrail User Guide*.

> **Important**
>
> We recommend that your application not pin Amazon S3 TLS certificates as AWS doesn't support pinning of publicly-trusted certificates. S3 automatically renews certificates and renewal can happen any time before certificate expiry. Renewing a certificate generates a new public-private key pair. If you've pinned an S3 certificate which has been recently renewed with a new public key, you won't be able to connect to S3 until your application uses the new certificate.

Also consider implementing ongoing detective controls by using the s3-bucket-ssl-requests-only managed AWS Config rule.

Consider using S3 Object Lock

With S3 Object Lock, you can store objects by using a "Write Once Read Many" (WORM) model. S3 Object Lock can help prevent accidental or inappropriate deletion of data. For example, you can use S3 Object Lock to help protect your AWS CloudTrail logs.

For more information, see Locking objects with Object Lock.

Enable S3 Versioning

S3 Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can easily recover from both unintended user actions and application failures.

Also consider implementing ongoing detective controls by using the s3-bucket-versioning-enabled managed AWS Config rule.

For more information, see Retaining multiple versions of objects with S3 Versioning.

Consider using S3 Cross-Region Replication

Although Amazon S3 stores your data across multiple geographically diverse Availability Zones by default, compliance requirements might dictate that you store data at even greater

distances. With S3 Cross-Region Replication (CRR), you can replicate data between distant AWS Regions to help satisfy these requirements. CRR enables automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see Replicating objects within and across Regions.

> **Note**
>
> CRR requires both the source and destination S3 buckets to have versioning enabled.

Also consider implementing ongoing detective controls by using the s3-bucket-replication-enabled managed AWS Config rule.

Consider using VPC endpoints for Amazon S3 access

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. VPC endpoints can help prevent traffic from traversing the open internet.

VPC endpoints for Amazon S3 provide multiple ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint by using S3 bucket policies.
- You can control which VPCs or VPC endpoints have access to your S3 buckets by using S3 bucket policies.
- You can help prevent data exfiltration by using a VPC that does not have an internet gateway.

For more information, see Controlling access from VPC endpoints with bucket policies.

Use managed AWS security services to monitor data security

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. These services can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of accounts.

For more information, see Monitoring data security with managed AWS security services.

Amazon S3 monitoring and auditing best practices

The following best practices for Amazon S3 can help detect potential security weaknesses and incidents.

Identify and audit all of your Amazon S3 buckets

Identification of your IT assets is a crucial aspect of governance and security. You need to have visibility of all your Amazon S3 resources to assess their security posture and take action on potential areas of weakness. To audit your resources, we recommend doing the following:

- Use Tag Editor to identify and tag security-sensitive or audit-sensitive resources, then use those tags when you need to search for these resources. For more information, see Searching for Resources to Tag in the *Tagging AWS Resources User Guide*.
- Use S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. For more information, see Cataloging and analyzing your data with S3 Inventory.
- Create resource groups for your Amazon S3 resources. For more information, see What are resource groups? in the *AWS Resource Groups User Guide*.

Implement monitoring by using AWS monitoring tools

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Amazon S3 and your AWS solutions. AWS provides several tools and services to help you monitor Amazon S3 and your other AWS services. For example, you can monitor Amazon CloudWatch metrics for Amazon S3, particularly the `PutRequests`, `GetRequests`, `4xxErrors`, and `DeleteRequests` metrics. For more information, see Monitoring metrics with Amazon CloudWatch and Logging and monitoring in Amazon S3.

For a second example, see Example: Amazon S3 Bucket Activity. This example describes how to create a CloudWatch alarm that is triggered when an Amazon S3 API call is made to PUT or `DELETE` a bucket policy, a bucket lifecycle, or a bucket replication configuration, or to PUT a bucket ACL.

Enable Amazon S3 server access logging

Server access logging provides detailed records of the requests that are made to a bucket. Server access logs can assist you in security and access audits, help you learn about your customer base, and understand your Amazon S3 bill. For instructions on enabling server access logging, see Logging requests with server access logging.

Also consider implementing ongoing detective controls by using the s3-bucket-logging-enabled AWS Config managed rule.

Use AWS CloudTrail

AWS CloudTrail provides a record of actions taken by a user, a role, or an AWS service in Amazon S3. You can use information collected by CloudTrail to determine the following:

- The request that was made to Amazon S3
- The IP address from which the request was made
- Who made the request
- When the request was made
- Additional details about the request

For example, you can identify CloudTrail entries for PUT actions that affect data access, in particular `PutBucketAcl`, `PutObjectAcl`, `PutBucketPolicy`, and `PutBucketWebsite`.

When you set up your AWS account, CloudTrail is enabled by default. You can view recent events in the CloudTrail console. To create an ongoing record of activity and events for your Amazon S3 buckets, you can create a trail in the CloudTrail console. For more information, see Logging data events in the *AWS CloudTrail User Guide*.

When you create a trail, you can configure CloudTrail to log data events. Data events are records of resource operations performed on or within a resource. In Amazon S3, data events record object-level API activity for individual buckets. CloudTrail supports a subset of Amazon S3 object-level API operations, such as `GetObject`, `DeleteObject`, and `PutObject`. For more information about how CloudTrail works with Amazon S3, see Logging Amazon S3 API calls using AWS CloudTrail. In the Amazon S3 console, you can also configure your S3 buckets to Enabling CloudTrail event logging for S3 buckets and objects.

AWS Config provides a managed rule (`cloudtrail-s3-dataevents-enabled`) that you can use to confirm that at least one CloudTrail trail is logging data events for your S3 buckets. For more information, see cloudtrail-s3-dataevents-enabled in the *AWS Config Developer Guide*.

Enable AWS Config

Several of the best practices listed in this topic suggest creating AWS Config rules. AWS Config helps you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config monitors resource configurations so that you can evaluate the recorded configurations against the desired secure configurations. With AWS Config, you can do the following:

- Review changes in configurations and relationships between AWS resources
- Investigate detailed resource-configuration histories
- Determine your overall compliance against the configurations specified in your internal guidelines

Using AWS Config can help you simplify compliance auditing, security analysis, change management, and operational troubleshooting. For more information, see Setting Up AWS Config with the Console in the *AWS Config Developer Guide*. When specifying the resource types to record, ensure that you include Amazon S3 resources.

> **Important**
>
> AWS Config managed rules only supports general purpose buckets when evaluating Amazon S3 resources. AWS Config doesn't record configuration changes for directory buckets. For more information, see AWS Config Managed Rules and List of AWS Config Managed Rules in the *AWS Config Developer Guide*.

For an example of how to use AWS Config, see How to Use AWS Config to Monitor for and Respond to Amazon S3 Buckets Allowing Public Access on the *AWS Security Blog*.

Use S3 Storage Lens

S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

With S3 Storage Lens, you can use metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads.

For example, you can identify buckets that don't have S3 Lifecycle rules to abort incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. For more information, see Understanding Amazon S3 Storage Lens.

Monitor AWS security advisories

We recommend that you regularly check the security advisories posted in Trusted Advisor for your AWS account. In particular, look for warnings about Amazon S3 buckets with "open access permissions." You can do this programmatically by using describe-trusted-advisor-checks.

Further, actively monitor the primary email address that's registered to each of your AWS accounts. AWS uses this email address to contact you about emerging security issues that might affect you.

AWS operational issues with broad impact are posted on the AWS Health Dashboard - Service health. Operational issues are also posted to individual accounts through the AWS Health Dashboard. For more information, see the AWS Health documentation.

Monitoring data security with managed AWS security services

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. They can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of AWS accounts.

AWS detection and response services can help you identify potential security misconfigurations, threats, or unexpected behaviors, so that you can quickly respond to potentially unauthorized or malicious activity in your environment. AWS data protection services can help you monitor and protect your data, accounts, and workloads from unauthorized access. They can also help you discover sensitive data, such as personally identifiable information (PII), in your Amazon S3 data estate.

To help you identify and evaluate data security and compliance risks, managed AWS security services generate findings to notify you of potential security events or issues with your Amazon S3 data. The findings provide relevant details that you can use to investigate, assess, and act upon these risks according to your incident-response workflows and policies. You can access findings data directly by using each service. You can also send the data to other applications, services, and systems, such as your security incident and event management system (SIEM).

To monitor the security of your Amazon S3 data, consider using these managed AWS security services.

Amazon GuardDuty

Amazon GuardDuty is a threat-detection service that continuously monitors your AWS accounts and workloads for malicious activity and delivers detailed security findings for visibility and remediation.

With the S3 protection feature in GuardDuty, you can configure GuardDuty to analyze AWS CloudTrail management and data events for your Amazon S3 resources. GuardDuty then monitors those events for malicious and suspicious activity. To inform the analysis and identify potential security risks, GuardDuty uses threat-intelligence feeds and machine learning.

GuardDuty can monitor different kinds of activity for your Amazon S3 resources. For example, CloudTrail management events for Amazon S3 include bucket-level operations, such as `ListBuckets`, `DeleteBucket`, and `PutBucketReplication`. CloudTrail data events for Amazon S3 include object-level operations, such as `GetObject`, `ListObjects`, and `PutObject`. If GuardDuty detects anomalous or potentially malicious activity, it generates a finding to notify you.

For more information, see Amazon S3 Protection in Amazon GuardDuty in the *Amazon GuardDuty User Guide*.

Amazon Detective

Amazon Detective simplifies the investigative process and helps you conduct faster, more effective security investigations. Detective provides prebuilt data aggregations, summaries, and context that can help you analyze and assess the nature and extent of possible security issues.

Detective automatically extracts time-based events, such as API calls from AWS CloudTrail and Amazon VPC Flow Logs for your AWS resources. It also ingests findings generated by Amazon GuardDuty. Detective then uses machine learning, statistical analysis, and graph theory to generate visualizations that help you conduct effective security investigations more quickly.

These visualizations provide a unified, interactive view of resource behaviors and the interactions between them over time. You can explore this behavior graph to examine potentially malicious actions, such as failed login attempts or suspicious API calls. You can also see how these actions affect resources, such as S3 buckets and objects.

For more information, see the Amazon Detective Administration Guide.

IAM Access Analyzer

AWS Identity and Access Management Access Analyzer (IAM Access Analyzer) can help you identify resources that are shared with an external entity. You can also use IAM Access Analyzer to validate IAM policies against policy grammar and best practices, and generate IAM policies based on access activity in your AWS CloudTrail logs.

IAM Access Analyzer uses logic-based reasoning to analyze resource policies in your AWS environment, such as bucket policies. With IAM Access Analyzer for S3, you're alerted when an S3 bucket is configured to allow access to anyone on the internet or other AWS accounts, including accounts outside your organization. For example, IAM Access Analyzer for S3 can report that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. For each public or shared bucket, you receive findings that indicate the source and level of public or shared access. With these findings, you can take immediate and precise corrective action to restore bucket access to what you intended.

For more information, see Reviewing bucket access using IAM Access Analyzer for S3.

Amazon Macie

Amazon Macie is a security service that discovers sensitive data by using machine learning and pattern matching. Macie provides visibility into data security risks, and enables automated protection against those risks. With Macie, you can automate the discovery and reporting of sensitive data in your Amazon S3 data estate to gain a better understanding of the data that your organization stores in S3.

To detect sensitive data with Macie, you can use built-in criteria and techniques that are designed to detect a large and growing list of sensitive data types for many countries and regions. These sensitive data types include multiple types of personally identifiable information (PII), financial data, and credentials data. You can also use custom criteria that you define—regular expressions that define text patterns to match and, optionally, character sequences and proximity rules that refine the results.

If Macie detects sensitive data in an S3 object, Macie generates a security finding to notify you. This finding provides information about the affected object, the types and number of occurrences of the sensitive data that Macie found, and additional details to help you investigate the affected S3 bucket and object. For more information, see the Amazon Macie User Guide.

AWS Security Hub CSPM

AWS Security Hub CSPM is a security-posture management service that performs security best-practice checks, aggregates alerts and findings from multiple sources into a single format, and enables automated remediation.

Security Hub CSPM collects and provides security findings data from integrated AWS Partner Network security solutions and AWS services, including Amazon Detective, Amazon GuardDuty, IAM Access Analyzer, and Amazon Macie. It also generates its own findings by running continuous, automated security checks based on AWS best practices and supported industry standards.

Security Hub CSPM then correlates and consolidates findings across providers to help you prioritize and process the most significant findings. It also provides support for custom actions, which you can use to invoke responses or remediation actions for specific classes of findings.

With Security Hub CSPM, you can assess the security and compliance status of your Amazon S3 resources, and you can do so as part of a broader analysis of your organization's security posture in individual AWS Regions and across multiple Regions. This includes analyzing security trends and identifying the highest-priority security issues. You can also aggregate findings from multiple AWS Regions, and monitor and process aggregated findings data from a single Region.

For more information, see Amazon Simple Storage Service controls in the *AWS Security Hub CSPM User Guide*.

Data protection in Amazon S3

Amazon S3 provides a highly durable storage infrastructure designed for mission-critical and primary data storage. S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive redundantly store objects on multiple devices across a minimum of three Availability Zones in an AWS Region. An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. Availability Zones are physically separated by a meaningful distance, many kilometers, from any other Availability Zone, although all are within 100 km (60 miles) of each other. The S3 One Zone-IA storage class stores data redundantly across multiple devices within a single Availability Zone. These services are designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy, and they also regularly verify the integrity of your data using checksums.

Amazon S3 standard storage offers the following features:

- Backed with the Amazon S3 Service Level Agreement.
- Designed to provide 99.999999999% durability and 99.99% availability of objects over a given year.
- S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive are all designed to sustain data in the event of the loss of an entire Amazon S3 Availability Zone.

Amazon S3 further protects your data using versioning. You can use versioning to preserve, retrieve, and restore every version of every object that is stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. By default, requests retrieve the most recently written version. You can retrieve older versions of an object by specifying a version of the object in a request.

Apart from S3 Versioning, you can also use Amazon S3 Object Lock and S3 Replication to protect your data. For more information, see Data protection in Amazon S3.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management, so that each user is given only the permissions necessary to fulfill their job duties.

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

The following security best practices also address data protection in Amazon S3:

- Implement server-side encryption
- Enforce encryption of data in transit
- Consider using Macie with Amazon S3
- Identify and audit all your Amazon S3 buckets
- Monitor Amazon Web Services security advisories

Protecting data with encryption

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

Data protection refers to protecting data while it's in transit (as it travels to and from Amazon S3) and at rest (while it is stored on disks in Amazon S3 data centers). You can protect data in transit by using Secure Socket Layer/Transport Layer Security (SSL/TLS) including hybrid post-quantum key exchange or client-side encryption. For protecting data at rest in Amazon S3, you have the following options:

- **Server-side encryption** – Amazon S3 encrypts your objects before saving them on disks in AWS data centers and then decrypts the objects when you download them.

  All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

  If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

  For more information about changing the default encryption configuration for your general purpose buckets, see Configuring default encryption.

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the Copy objects action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and the *AWS Storage Blog* post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations.

For more information about each option for server-side encryption, see Protecting data with server-side encryption.

To configure server-side encryption, see:

- Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)
- Specifying server-side encryption with AWS KMS (SSE-KMS)
- the section called "Specifying DSSE-KMS"
- Specifying server-side encryption with customer-provided keys (SSE-C)

- **Client-side encryption** – You encrypt your data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, encryption keys, and related tools.

  To configure client-side encryption, see Protecting data by using client-side encryption.

To see which percentage of your storage bytes are encrypted, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Assessing your storage activity and usage with S3 Storage Lens. For a complete list of metrics, see S3 Storage Lens metrics glossary.

For more information about server-side encryption, client-side encryption, and encryption in transit, review the following topics.

Topics

- Protecting data with server-side encryption

- Protecting data by using client-side encryption
- Protecting data in transit with encryption

Protecting data with server-side encryption

Important

Amazon Simple Storage Service now applies a new default bucket security setting that automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. In April 2026, Amazon S3 deployed an update so all new general purpose buckets have SSE-C encryption disabled for all new write requests. For existing buckets in AWS accounts with no SSE-C encrypted objects, Amazon S3 also disabled SSE-C for all new write requests. With this change, applications that need SSE-C encryption must deliberately enable SSE-C by using the PutBucketEncryption API operation after creating a new bucket. For more information about this change, see Default SSE-C setting for new buckets FAQ.

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it. As long as you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For example, if you share your objects by using a presigned URL, that URL works the

same way for both encrypted and unencrypted objects. Additionally, when you list objects in your bucket, the list API operations return a list of all objects, regardless of whether they are encrypted.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see Configuring default encryption.

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the Copy objects action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and the *AWS Storage Blog* post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations.

> **Note**
>
> You can't apply different types of server-side encryption to the same object simultaneously.

If you need to encrypt your existing objects, use S3 Batch Operations and S3 Inventory. For more information, see Encrypting objects with Amazon S3 Batch Operations and Performing object operations in bulk with Batch Operations.

When storing data in Amazon S3 you have four mutually exclusive options for server-side encryption, depending on how you choose to manage the encryption keys and the number of encryption layers that you want to apply.

Server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 buckets have encryption configured by default. The default option for server-side encryption is with Amazon S3 managed keys (SSE-S3). Each object is encrypted with a unique key. As an additional safeguard, SSE-S3 encrypts the key itself with a root key that it regularly rotates. SSE-S3 uses one of the strongest block ciphers available, 256-bit Advanced Encryption Standard (AES-256), to encrypt your data. For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)

Server-side encryption with AWS KMS keys (SSE-KMS) is provided through an integration of the AWS KMS service with Amazon S3. With AWS KMS, you have more control over your keys. For example, you can view separate keys, edit control policies, and follow the keys in AWS CloudTrail. Additionally, you can create and manage customer managed keys or use AWS managed keys that are unique to you, your service, and your Region. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS).

Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)

Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) is similar to SSE-KMS, but DSSE-KMS applies two independent layers of AES-256 encryption instead of one layer: first using a AWS KMS data encryption key, then using a separate Amazon S3-managed encryption key. Because both layers of encryption are applied to an object on the server side, you can use a wide range of AWS services and tools to analyze data in S3 while using an encryption method that can satisfy compliance requirements for multilayer encryption. For more information, see Using dual-layer server-side encryption with AWS KMS keys (DSSE-KMS).

Server-side encryption with customer-provided keys (SSE-C)

With server-side encryption with customer-provided keys (SSE-C), you manage the encryption keys, and Amazon S3 manages the encryption as it writes to disks and the decryption when you access your objects. For more information, see Using server-side encryption with customer-provided keys (SSE-C).

Note

Objects encrypted with SSE-C do not support annotations. Attempting to add an annotation to an SSE-C encrypted object returns an error. For all other encryption types, annotations inherit the encryption configuration of the parent object. S3 Bucket Keys are supported for annotations on SSE-KMS encrypted objects.

Note

When using access points for Amazon FSx file systems using S3 access points you have one option for server-side encryption.

Server-side encryption with Amazon FSx (SSE-FSX)

All Amazon FSx file systems have encryption configured by default and are encrypted at rest with keys managed using AWS Key Management Service. Data is automatically encrypted and decrypted by on the file system as data is being written to and read from the file system. These processes are handled transparently by Amazon FSx.

Setting default server-side encryption behavior for Amazon S3 buckets

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

All Amazon S3 buckets have encryption configured by default, and objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption setting applies to all objects in your Amazon S3 buckets.

If you need more control over your keys, such as managing key rotation and access policy grants, you can choose to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about editing KMS keys, see Editing keys in *AWS Key Management Service Developer Guide*.

> **Note**
>
> We've changed buckets to encrypt new object uploads automatically. If you previously created a bucket without default encryption, Amazon S3 will enable encryption by default for the bucket using SSE-S3. There will be no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or SSE-KMS configured. If you want to encrypt your objects with SSE-KMS, you must change the encryption type in your bucket settings. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS).

When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys to decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of encryption. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

To identify buckets that have SSE-KMS enabled for default encryption, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Using S3 Storage Lens to protect your data.

When you use server-side encryption, Amazon S3 encrypts an object before saving it to disk and decrypts it when you download the object. For more information about protecting data using server-side encryption and encryption-key management, see Protecting data with server-side encryption.

For more information about the permissions required for default encryption, see PutBucketEncryption in the *Amazon Simple Storage Service API Reference*.

You can configure the Amazon S3 default encryption behavior for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Encrypting existing objects

To encrypt your existing unencrypted Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation. You can use the Batch Operations Copy operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and the *AWS Storage Blog* post Encrypting objects with Amazon S3 Batch Operations.

You can also encrypt existing objects by using the `CopyObject` API operation or the `copy-object` AWS CLI command. For more information, see the *AWS Storage Blog* post Encrypting existing Amazon S3 objects with the AWS CLI.

> **Important**
>
> If your bucket is a target destination for server access log delivery, the bucket must use Amazon S3 managed keys (SSE-S3). If the destination bucket uses SSE-KMS default encryption, log objects might be created but encrypted with a key that you can't access.

Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (`aws/s3`) is used.
- If you're uploading or accessing S3 objects by using AWS Identity and Access Management (IAM) principals that are in the same AWS account as your KMS key, you can use the AWS managed key (`aws/s3`).
- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted `Encrypt` permission to. For more information, see Allow key users to use a KMS key for cryptographic operations in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?

Using default encryption with replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.
- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

For more information about using default encryption with SSE-KMS, see Replicating encrypted objects.

Using Amazon S3 Bucket Keys with default encryption

When you configure your bucket to use SSE-KMS as the default encryption behavior for new objects, you can also configure S3 Bucket Keys. S3 Bucket Keys decrease the number of transactions from Amazon S3 to AWS KMS to reduce the cost of SSE-KMS.

When you configure your bucket to use S3 Bucket Keys for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create a unique data key for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations.

For more information about using S3 Bucket Keys, see Using Amazon S3 Bucket Keys.

Configuring default encryption

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

Amazon S3 buckets have bucket encryption enabled by default, and new objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all new objects in your Amazon S3 buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can elect to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about SSE-KMS, see Specifying server-side encryption with AWS KMS (SSE-KMS). For more information about DSSE-KMS, see the section called "Dual-layer server-side encryption (DSSE-KMS)".

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

When you set default bucket encryption to SSE-KMS, you can also configure an S3 Bucket Key to reduce your AWS KMS request costs. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

> **Note**
>
> If you use PutBucketEncryption to set your default bucket encryption to SSE-KMS, you should verify that your KMS key ID is correct. Amazon S3 does not validate the KMS key ID provided in PutBucketEncryption requests.

There are no additional charges for using default encryption for S3 buckets. Requests to configure the default encryption behavior incur standard Amazon S3 request charges. For information about pricing, see Amazon S3 pricing. For SSE-KMS and DSSE-KMS, AWS KMS charges apply and are listed at AWS KMS pricing.

Server-side encryption with customer-provided keys (SSE-C) is not supported for default encryption.

You can configure Amazon S3 default encryption for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Changes to note before enabling default encryption

After you enable default encryption for a bucket, the following encryption behavior applies:

- There is no change to the encryption of the objects that existed in the bucket before default encryption was enabled.
- When you upload objects after enabling default encryption:
  - If your PUT request headers don't include encryption information, Amazon S3 uses the bucket's default encryption settings to encrypt the objects.
  - If your PUT request headers include encryption information, Amazon S3 uses the encryption information from the PUT request to encrypt objects before storing them in Amazon S3.
- If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.
- If this bucket is used as a destination for server access logging, the destination bucket must use Amazon S3 managed keys (SSE-S3). If the destination bucket uses SSE-KMS default encryption, Amazon S3 might deliver log objects that are encrypted with a key that you can't access. To resolve this, change the destination bucket's default encryption to SSE-S3. For more information about server access logging, see Logging requests with server access logging.

> **Note**
>
> Objects uploaded before default encryption was enabled will not be encrypted. For information about encrypting existing objects, see the section called "Setting default bucket encryption".

Using the S3 console

To configure default encryption on an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. To configure encryption, under **Encryption type**, choose one of the following:

   - **Server-side encryption with Amazon S3 managed keys (SSE-S3)**
   - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
   - **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**

   > **Important**
   >
   > If you use the SSE-KMS or DSSE-KMS options for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

   Buckets and new objects are encrypted by default with SSE-S3, unless you specify another type of default encryption for your buckets. For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets.

   For more information about using Amazon S3 server-side encryption to encrypt your data, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).
7. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**, do the following:

   a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

  Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console only lists 100 KMS keys per Region. If you have more than 100 KMS keys in the same Region, you can only see the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter the KMS key ARN.
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 only supports symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

For more information about using SSE-KMS with Amazon S3, see Using server-side encryption with AWS KMS keys (SSE-KMS). For more information about using DSSE-KMS, see the section called "Dual-layer server-side encryption (DSSE-KMS)".

b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable an S3 Bucket Key. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

> **Note**
>
> S3 Bucket Keys aren't supported for DSSE-KMS.

8. Choose **Save changes**.

Using the AWS CLI

These examples show you how to configure default encryption by using SSE-S3 or by using SSE-KMS with an S3 Bucket Key.

For more information about default encryption, see Setting default server-side encryption behavior for Amazon S3 buckets. For more information about using the AWS CLI to configure default encryption, see put-bucket-encryption.

Example– Default encryption with SSE-S3

This example configures default bucket encryption with Amazon S3 managed keys.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
    "Rules": [
        {
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "AES256"
            }
        }
    ]
}'
```

Example– Default encryption with SSE-KMS using an S3 Bucket Key

This example configures default bucket encryption with SSE-KMS using an S3 Bucket Key.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
    "Rules": [
```

```
            {
                "ApplyServerSideEncryptionByDefault": {
                    "SSEAlgorithm": "aws:kms",
                    "KMSMasterKeyID": "KMS-Key-ARN"
                },
                "BucketKeyEnabled": true
            }
        ]
    }'
```

Using the REST API

Use the REST API `PutBucketEncryption` operation to enable default encryption and to set the type of server-side encryption to use—SSE-S3, SSE-KMS, or DSSE-KMS.

For more information, see PutBucketEncryption in the *Amazon Simple Storage Service API Reference*.

Monitoring default encryption with AWS CloudTrail and Amazon EventBridge

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

You can track default encryption configuration requests for Amazon S3 buckets by using AWS CloudTrail events. The following API event names are used in CloudTrail logs:

- `PutBucketEncryption`
- `GetBucketEncryption`
- `DeleteBucketEncryption`

You can also create EventBridge rules to match the CloudTrail events for these API calls. For more information about CloudTrail events, see Enable logging for objects in a bucket using the console. For more information about EventBridge events, see Events from AWS services.

You can use CloudTrail logs for object-level Amazon S3 actions to track PUT and POST requests to Amazon S3. You can use these actions to verify whether default encryption is being used to encrypt objects when incoming PUT requests don't have encryption headers.

When Amazon S3 encrypts an object by using the default encryption settings, the log includes one of the following fields as the name-value pair: `"SSEApplied":"Default_SSE_S3"`, `"SSEApplied":"Default_SSE_KMS"`, or `"SSEApplied":"Default_DSSE_KMS"`.

When Amazon S3 encrypts an object by using the PUT encryption headers, the log includes one of the following fields as the name-value pair: `"SSEApplied":"SSE_S3"`, `"SSEApplied":"SSE_KMS"`, `"SSEApplied":"DSSE_KMS"`, or `"SSEApplied":"SSE_C"`.

For multipart uploads, this information is included in your `InitiateMultipartUpload` API operation requests. For more information about using CloudTrail and CloudWatch, see Logging and monitoring in Amazon S3.

Default encryption FAQ

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. SSE-S3, which uses 256-bit Advanced Encryption Standard (AES-256), is automatically applied to all new buckets and to any existing S3 bucket that doesn't already have default encryption configured. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

The following sections answer questions about this update.

Does Amazon S3 change the default encryption settings for my existing buckets that already have default encryption configured?

No. There are no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or server-side encryption with AWS Key Management Service (AWS KMS) keys

(SSE-KMS) configured. For more information about how to set the default encryption behavior for buckets, see Setting default server-side encryption behavior for Amazon S3 buckets. For more information about SSE-S3 and SSE-KMS encryption settings, see Protecting data with server-side encryption.

Is default encryption enabled on my existing buckets that don't have default encryption configured?

Yes. Amazon S3 now configures default encryption on all existing unencrypted buckets to apply server-side encryption with S3 managed keys (SSE-S3) as the base level of encryption for new objects uploaded to these buckets. Objects that are already in an existing unencrypted bucket won't be automatically encrypted.

How can I view the default encryption status of new object uploads?

Currently, you can view the default encryption status of new object uploads in AWS CloudTrail logs, S3 Inventory, and S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

- To view your CloudTrail events, see Viewing CloudTrail events in the CloudTrail console in the *AWS CloudTrail User Guide*. CloudTrail logs provide API tracking for PUT and POST requests to Amazon S3. When default encryption is being used to encrypt objects in your buckets, the CloudTrail logs for PUT and POST API requests will include the following field as the name-value pair: `"SSEApplied":"Default_SSE_S3"`.
- To view the automatic encryption status of new object uploads in S3 Inventory, configure an S3 Inventory report to include the **Encryption** metadata field, and then see the encryption status of each new object in the report. For more information, see Setting up Amazon S3 Inventory.
- To view the automatic encryption status for new object uploads in S3 Storage Lens, configure an S3 Storage Lens dashboard and see the **Encrypted bytes** and **Encrypted object count** metrics in the **Data protection** category of the dashboard. For more information, see Using the S3 console and Viewing S3 Storage Lens metrics on the dashboards.
- To view the automatic bucket-level encryption status in the Amazon S3 console, check the **Default encryption** of your Amazon S3 buckets in the Amazon S3 console. For more information, see Configuring default encryption.
- To view the automatic encryption status as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs, check the response header `x-amz-server-side-encryption` when you use object action APIs, such as PutObject and GetObject.

What do I have to do to take advantage of this change?

You are not required to make any changes to your existing applications. Because default encryption is enabled for all of your buckets, all new objects uploaded to Amazon S3 are automatically encrypted.

Can I disable encryption for the new objects being written to my bucket?

No. SSE-S3 is the new base level of encryption that's applied to all the new objects being uploaded to your bucket. You can no longer disable encryption for new object uploads.

Will my charges be affected?

No. Default encryption with SSE-S3 is available at no additional cost. You will be billed for storage, requests, and other S3 features, as usual. For pricing, see Amazon S3 pricing.

Will Amazon S3 encrypt my existing objects that are unencrypted?

No. Beginning on January 5, 2023, Amazon S3 only automatically encrypts new object uploads. To encrypt existing objects, you can use S3 Batch Operations to create encrypted copies of your objects. These encrypted copies will retain the existing object data and name and will be encrypted by using the encryption keys that you specify. For more details, see Encrypting objects with Amazon S3 Batch Operations in the *AWS Storage Blog*.

I did not enable encryption for my buckets before this release. Do I need to change the way that I access objects?

No. Default encryption with SSE-S3 automatically encrypts your data as it's written to Amazon S3 and decrypts it for you when you access it. There is no change in the way that you access objects that are automatically encrypted.

Do I need to change the way that I access my client-side encrypted objects?

No. All client-side encrypted objects that are encrypted before being uploaded into Amazon S3 arrive as encrypted ciphertext objects within Amazon S3. These objects will now have an additional layer of SSE-S3 encryption. Your workloads that use client-side encrypted objects will not require any changes to your client services or authorization settings.

> **Note**
>
> HashiCorp Terraform users that aren't using an updated version of the AWS Provider might see an unexpected drift after creating new S3 buckets with no customer defined encryption

configuration. To avoid this drift, update your Terraform AWS Provider version to one of the following versions: any 4.x release, 3.76.1, or 2.70.4.

Updating server-side encryption for existing data

All Amazon S3 buckets have encryption configured by default, and objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This default encryption setting applies to all new objects in your Amazon S3 buckets.

Using the `UpdateObjectEncryption` API operation, you can atomically update the server-side encryption type of an existing encrypted object in a general purpose bucket from server-side encryption with Amazon S3 managed encryption (SSE-S3) to server-side encryption with AWS Key Management Service (AWS KMS) encryption keys (SSE-KMS). The `UpdateObjectEncryption` API operation uses envelope encryption to re-encrypt the data key used to encrypt and decrypt your object with your newly specified server-side encryption type.

Amazon S3 performs this encryption type update without any data movement. In other words, when you use the `UpdateObjectEncryption` operation, your data isn't copied, archived objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive aren't restored, and objects in the S3 Intelligent-Tiering storage class aren't moved between tiers. Additionally, the `UpdateObjectEncryption` operation preserves all object metadata properties, including the storage class, creation date, last modified date, ETag, and checksum properties.

The `UpdateObjectEncryption` operation is supported for all S3 storage classes that are supported by general purpose buckets. You can use the `UpdateObjectEncryption` operation to do the following:

- Change encrypted objects from server-side encryption with Amazon S3 managed encryption (SSE-S3) to server-side encryption with AWS Key Management Service (AWS KMS) encryption keys (SSE-KMS).
- Update object-level SSE-KMS encrypted objects to use S3 Bucket Keys, which decreases the AWS KMS request traffic from Amazon S3 to AWS KMS. For more information, see the section called "Using Amazon S3 Bucket Keys".
- Change the customer-managed KMS key that's used to encrypt your data so that you can comply with custom key-rotation standards.

> **Note**
>
> Source objects that are unencrypted, or encrypted with either dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) or customer-provided encryption keys (SSE-C) aren't supported by this operation.

The `UpdateObjectEncryption` operation is typically completed in milliseconds regardless of the size of the object or the storage class, including S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. This operation doesn't count as an access for S3 Intelligent-Tiering, so objects in the Infrequent Access tier or the Archive Instant Access tier won't automatically tier back to the Frequent Access tier if you change the server-side encryption type of your object.

`UpdateObjectEncryption` is an object-level (data plane) API operation that's logged to Amazon S3 server access logs and AWS CloudTrail data events. For more information, see the section called "Logging options".

The `UpdateObjectEncryption` operation is priced the same as `PUT`, `COPY`, `POST`, and `LIST` requests (per 1,000 requests) and is always charged as an S3 Standard storage class request regardless of the underlying object's storage class. For more information, see Amazon S3 pricing.

Restrictions and considerations

When using the `UpdateObjectEncryption` operation, the following restrictions and considerations apply:

- The `UpdateObjectEncryption` operation doesn't support objects that are unencrypted or objects that are encrypted with either dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) or customer-provided encryption keys (SSE-C). Additionally, you cannot specify SSE-S3 as the requested new encryption type `UpdateObjectEncryption` request.
- You can use the `UpdateObjectEncryption` operation to update objects in buckets that have S3 Versioning enabled. To update the encryption type of a particular version, you must specify a version ID in your `UpdateObjectEncryption` request. If you don't specify version ID, the `UpdateObjectEncryption` request acts on the current version of the object. For more information about S3 Versioning, see the section called "Retaining multiple versions of objects".
- The `UpdateObjectEncryption` operation fails on any object that has an S3 Object Lock retention mode or legal hold applied to it. If an object has a governance-mode retention period or a legal hold, you must first remove the Object Lock status on the object before you issue your

`UpdateObjectEncryption` request. You can't use the `UpdateObjectEncryption` operation with objects that have an Object Lock compliance mode retention period applied to them. For more information about S3 Object Lock, see the section called “Locking objects”.

- `UpdateObjectEncryption` requests on source buckets with live replication enabled won't initiate replica events in the destination bucket. If you want to change the encryption type of objects in both your source and destination buckets, you must initiate separate `UpdateObjectEncryption` requests on the objects in the source and destination buckets.
- By default, all `UpdateObjectEncryption` requests that specify a customer-managed KMS key are restricted to KMS keys that are owned by the bucket owner's AWS account. If you're using AWS Organizations, you can request the ability to use AWS KMS keys owned by other member accounts within your organization by contacting AWS Support.
- If you use S3 Batch Replication to replicate datasets cross region and your objects previously had their server-side encryption type updated from SSE-S3 to SSE-KMS, you might need additional permissions. On the source region bucket, you must have `kms:decrypt` permissions. Then, you will need the `kms:decrypt` and `kms:encrypt` permissions for the bucket in the destination region.
- You must provide a full KMS key ARN in your `UpdateObjectEncryption` request. You can't use an alias name or alias ARN. You can determine the full KMS Key ARN in the AWS KMS Console or using the AWS KMS `DescribeKey` API.

Required permissions

To perform the `UpdateObjectEncryption` operation, you must have the following permissions:

- `s3:UpdateObjectEncryption`
- `kms:Encrypt`
- `kms:Decrypt`
- `kms:GenerateDataKey`
- `kms:ReEncrypt*`

If you're using AWS Organizations, to use this operation with customer-managed KMS keys from other AWS accounts within your organization, you must have the `organizations:DescribeAccount` permission. You must also request the ability to use AWS KMS keys owned by other member accounts within your organization by contacting AWS Support.

To perform the `UpdateObjectEncryption` operation, add the following AWS Identity and Access Management (IAM) policy to your IAM role. To use this policy, replace *amzn-s3-demo-bucket* with the name of your general purpose bucket, and replace the other *user input placeholders* with your own information.

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Sid": "AllowUpdateObjectEncryption",
            "Effect": "Allow",
            "Action": [
                "s3:UpdateObjectEncryption",
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:GenerateDataKey",
                "kms:ReEncrypt*",
                "organizations:DescribeAccount"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*",
                "arn:aws:kms:us-east-1:111122223333:key/01234567-89ab-
cdef-0123-456789abcdef"
            ]
        }
    ]
}
```

Updating encryption in bulk

To update the server-side encryption type of more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You can provide S3 Batch Operations with a list of objects to operate on, or you can direct Batch Operations to generate an object list based object metadata, including prefix, storage class, creation date, encryption type, KMS key ARN, or S3 Bucket Key status. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects within a bucket containing petabytes of data. For more information about Batch Operations, see the section called “Performing object operations in bulk”.

The S3 Batch Operations feature tracks progress, sends notifications, and stores a detailed completion report of all actions, providing a fully managed, auditable, serverless experience. You

can use S3 Batch Operations through the Amazon S3 console, AWS Command Line Interface (AWS CLI) AWS SDKs, or the Amazon S3 REST API. For more information, see the section called "Update object encryption".

Updating encryption for objects

You can update the server-side encryption type for an object through the AWS Command Line Interface (AWS CLI) AWS SDKs, or the Amazon S3 REST API.

Update encryption for an object

Using the AWS CLI

To run the following commands, you must have the AWS CLI installed and configured. If you don't have the AWS CLI installed, see Install or update to the latest version of the AWS CLI in the *AWS Command Line Interface User Guide*.

Alternatively, you can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? and Getting started with AWS CloudShell in the *AWS CloudShell User Guide*.

To update encryption for an object by using the AWS CLI

To use the following example command, replace the *`user input placeholders`* with your own information.

1. Use the following command to update encryption for a single object (*`index.html`*) in your general purpose bucket (for example, *`amzn-s3-demo-bucket`*) to use SSE-KMS with an S3 Bucket Key:

```
aws s3api update-object-encryption \
--bucket amzn-s3-demo-bucket \
--key index.html \
--object-encryption '{"SSEKMS": { "KMSKeyArn": "arn:aws:kms:us-
east-1:111122223333:key/f12a345a-678e-9bbb-1025-62e317037583", "BucketKeyEnabled":
 true }}'
```

> **Note**
>
> You must specify the full AWS KMS key Amazon Resource Name (ARN). The KMS key ID and KMS key alias aren't supported.

2. Run the `head-object` command to view the updated encryption type of your object:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html
```

Using the REST API

You can send REST requests to update encryption for an object. For more information, see UpdateObjectEncryption.

Using the AWS SDKs

You can use the AWS SDKs to update encryption for an object. For more information, see the list of supported SDKs.

Java

Example

The following AWS SDK for Java 2.x example updates the encryption type to SSE-KMS for an object in a general purpose bucket.

```
    public void updateObjectEncryption(String bucketName,
                                       String objectKey,
                                       String versionId,
                                       String kmsKeyArn,
                                       boolean bucketKeyEnabled) {
        // Create the target object encryption type.
        ObjectEncryption objectEncryption = ObjectEncryption.builder()
                .ssekms(SSEKMSEncryption.builder()
                        .kmsKeyArn(kmsKeyArn)
                        .bucketKeyEnabled(bucketKeyEnabled)
                        .build())
                .build();

        // Create the UpdateObjectEncryption request.
```

```
        UpdateObjectEncryptionRequest request =
 UpdateObjectEncryptionRequest.builder()
                .bucket(bucketName)
                .key(objectKey)
                .versionId(versionId)
                .objectEncryption(objectEncryption)
                .build();

        // Update the object encryption.
        try {
            getS3Client().updateObjectEncryption(request);
            logger.info("Object encryption updated to SSE-KMS for {} in bucket {}",
 objectKey, bucketName);
        } catch (S3Exception e) {
            logger.error("Failed to update to object encryption: {} - Error code:
 {}", e.awsErrorDetails().errorMessage(),
                    e.awsErrorDetails().errorCode());
            throw e;
        }
    }
```

Python

Example

The following AWS SDK for Python (Boto3) example shows how to update the encryption type to SSE-KMS for an object in a general purpose bucket.

```
response = client.update_object_encryption(
    Bucket='string',
    Key='string',
    VersionId='string',
    ObjectEncryption={
        'SSEKMS': {
                'KMSKeyArn': 'string',
                'BucketKeyEnabled': True|False
        }
    }
)
```

Using server-side encryption with Amazon S3 managed keys (SSE-S3)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

All new object uploads to Amazon S3 buckets are encrypted by default with server-side encryption with Amazon S3 managed keys (SSE-S3).

Server-side encryption protects data at rest. Amazon S3 encrypts each object with a unique key. As an additional safeguard, it encrypts the key itself with a key that it rotates regularly. Amazon S3 server-side encryption uses 256-bit Advanced Encryption Standard Galois/Counter Mode (AES-GCM) to encrypt all uploaded objects.

There are no additional fees for using server-side encryption with Amazon S3 managed keys (SSE-S3). However, requests to configure the default encryption feature incur standard Amazon S3 request charges. For information about pricing, see Amazon S3 pricing.

If you require your data uploads to be encrypted using only Amazon S3 managed keys, you can use the following bucket policy. For example, the following bucket policy denies permissions to upload an object unless the request includes the `x-amz-server-side-encryption` header to request server-side encryption:

JSON

```
{
  "Version":"2012-10-17",
  "Id": "PutObjectPolicy",
  "Statement": [
    {
      "Sid": "DenyObjectsThatAreNotSSES3",
```

```
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
      "Condition": {
        "StringNotEquals": {
          "s3:x-amz-server-side-encryption": "AES256"
        }
      }
    }
  ]
}
```

Note

Server-side encryption encrypts only the object data, not the object metadata.

Note

The `s3:x-amz-server-side-encryption` condition key used in bucket policies is an IAM condition key namespace and differs from the `x-amz-server-side-encryption` HTTP header shown in CloudTrail logs. Both refer to the same encryption setting, but use different formats. Additionally, this Deny policy might block writes from (such as Elastic Load Balancing access logs or Amazon CloudFront logs) that deliver objects to your bucket without specifying the encryption header.

API support for server-side encryption

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side

encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see Configuring default encryption.

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the Copy objects action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and the *AWS Storage Blog* post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations.

To configure server-side encryption by using the object creation REST APIs, you must provide the `x-amz-server-side-encryption` request header. For information about the REST APIs, see Using the REST API.

The following Amazon S3 APIs support this header:

- **PUT operations** – Specify the request header when uploading data using the PUT API. For more information, see PUT Object.
- **Initiate Multipart Upload** – Specify the header in the initiate request when uploading large objects using the multipart upload API operation. For more information, see Initiate Multipart Upload.
- **COPY operations** – When you copy an object, you have both a source object and a target object. For more information, see PUT Object - Copy.

> **Note**
>
> When using a POST operation to upload an object, instead of providing the request header, you provide the same information in the form fields. For more information, see POST Object.

The AWS SDKs also provide wrapper APIs that you can use to request server-side encryption. You can also use the AWS Management Console to upload objects and request server-side encryption.

For more general information, see AWS KMS concepts in the *AWS Key Management Service Developer Guide*.

Topics

- Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)

Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see Configuring default encryption.

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the Copy objects action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and the *AWS Storage Blog* post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations.

You can specify SSE-S3 by using the S3 console, REST APIs, AWS SDKs, and AWS Command Line Interface (AWS CLI). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.

Using the S3 console

This topic describes how to set or change the type of encryption an object by using the AWS Management Console. When you copy an object by using the console, Amazon S3 copies the object as is. That means that if the source object is encrypted, the target object is also encrypted. You can use the console to add or change encryption for an object.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the AWS CLI or AWS SDKs to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see the section called "Required permissions for S3 API operations". For example policies that grant this permission, see the section called "Identity-based policy examples".
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.

6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.

    - Under **Encryption type**, choose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).
8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Save changes**.

> **Note**
>
> This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

At the time of object creation—that is, when you are uploading a new object or making a copy of an existing object—you can specify if you want Amazon S3 to encrypt your data with Amazon S3 managed keys (SSE-S3) by adding the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `AES256`, which Amazon S3 supports. Amazon S3 confirms that your object is stored with SSE-S3 by returning the response header `x-amz-server-side-encryption`.

The following REST upload API operations accept the `x-amz-server-side-encryption` request header.

- PUT Object
- PUT Object - Copy
- POST Object

- Initiate Multipart Upload

When uploading large objects by using the multipart upload API operation, you can specify server-side encryption by adding the `x-amz-server-side-encryption` header to the Initiate Multipart Upload request. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored using SSE-S3.

- PUT Object
- PUT Object - Copy
- POST Object
- Initiate Multipart Upload
- Upload Part
- Upload Part - Copy
- Complete Multipart Upload
- Get Object
- Head Object

> **Note**
>
> Do not send encryption request headers for `GET` requests and `HEAD` requests if your object uses SSE-S3, or you'll get an HTTP status code 400 (Bad Request) error.

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use server-side encryption with Amazon S3 managed encryption keys (SSE-S3). This section provides examples of using the AWS SDKs in multiple languages. For information about other SDKs, go to Sample Code and Libraries.

Java

When you use the AWS SDK for Java to upload an object, you can use SSE-S3 to encrypt it. To request server-side encryption, use the `ObjectMetadata` property of the `PutObjectRequest` to set the `x-amz-server-side-encryption` request header. When you call the `putObject()` method of the `AmazonS3Client`, Amazon S3 encrypts and saves the data.

You can also request SSE-S3 encryption when uploading objects with the multipart upload API operation:

- When using the high-level multipart upload API operation, you use the `TransferManager` methods to apply server-side encryption to objects as you upload them. You can use any of the upload methods that take `ObjectMetadata` as a parameter. For more information, see Uploading an object using multipart upload.
- When using the low-level multipart upload API operation, you specify server-side encryption when you initiate the multipart upload. You add the `ObjectMetadata` property by calling the `InitiateMultipartUploadRequest.setObjectMetadata()` method. For more information, see Using the AWS SDKs (low-level API).

You can't directly change the encryption state of an object (encrypting an unencrypted object or decrypting an encrypted object). To change an object's encryption state, you make a copy of the object, specifying the desired encryption state for the copy, and then delete the original object. Amazon S3 encrypts the copied object only if you explicitly request server-side encryption. To request encryption of the copied object through the Java API, use the `ObjectMetadata` property to specify server-side encryption in the `CopyObjectRequest`.

Example

The following example shows how to set server-side encryption by using the AWS SDK for Java. It shows how to perform the following tasks:

- Upload a new object by using SSE-S3.
- Change an object's encryption state (in this example, encrypting a previously unencrypted object) by making a copy of the object.
- Check the encryption state of the object.

For more information about server-side encryption, see Using the REST API. For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

        String keyNameToEncrypt = "*** Key name for an object to upload and encrypt
 ***";
        String keyNameToCopyAndEncrypt = "*** Key name for an unencrypted object to
 be encrypted by copying ***";
        String copiedObjectKeyName = "*** Key name for the encrypted copy of the
 unencrypted object ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();

            // Upload an object and encrypt it with SSE.
            uploadObjectWithSSEEncryption(s3Client, bucketName, keyNameToEncrypt);

            // Upload a new unencrypted object, then change its encryption state
            // to encrypted by making a copy.
            changeSSEEncryptionStatusByCopying(s3Client,
                    bucketName,
                    keyNameToCopyAndEncrypt,
                    copiedObjectKeyName);
```

```
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }

    private static void uploadObjectWithSSEEncryption(AmazonS3 s3Client, String
bucketName, String keyName) {
        String objectContent = "Test object encrypted with SSE";
        byte[] objectBytes = objectContent.getBytes();

        // Specify server-side encryption.
        ObjectMetadata objectMetadata = new ObjectMetadata();
        objectMetadata.setContentLength(objectBytes.length);

objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
        PutObjectRequest putRequest = new PutObjectRequest(bucketName,
                keyName,
                new ByteArrayInputStream(objectBytes),
                objectMetadata);

        // Upload the object and check its encryption status.
        PutObjectResult putResult = s3Client.putObject(putRequest);
        System.out.println("Object \"" + keyName + "\" uploaded with SSE.");
        printEncryptionStatus(putResult);
    }

    private static void changeSSEEncryptionStatusByCopying(AmazonS3 s3Client,
            String bucketName,
            String sourceKey,
            String destKey) {
        // Upload a new, unencrypted object.
        PutObjectResult putResult = s3Client.putObject(bucketName, sourceKey,
"Object example to encrypt by copying");
        System.out.println("Unencrypted object \"" + sourceKey + "\" uploaded.");
        printEncryptionStatus(putResult);

        // Make a copy of the object and use server-side encryption when storing the
        // copy.
```

```
        CopyObjectRequest request = new CopyObjectRequest(bucketName,
                sourceKey,
                bucketName,
                destKey);
        ObjectMetadata objectMetadata = new ObjectMetadata();

 objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
        request.setNewObjectMetadata(objectMetadata);

        // Perform the copy operation and display the copy's encryption status.
        CopyObjectResult response = s3Client.copyObject(request);
        System.out.println("Object \"" + destKey + "\" uploaded with SSE.");
        printEncryptionStatus(response);

        // Delete the original, unencrypted object, leaving only the encrypted copy
 in
        // Amazon S3.
        s3Client.deleteObject(bucketName, sourceKey);
        System.out.println("Unencrypted object \"" + sourceKey + "\" deleted.");
    }

    private static void printEncryptionStatus(SSEResultBase response) {
        String encryptionStatus = response.getSSEAlgorithm();
        if (encryptionStatus == null) {
            encryptionStatus = "Not encrypted with SSE";
        }
        System.out.println("Object encryption status is: " + encryptionStatus);
    }
}
```

.NET

When you upload an object, you can direct Amazon S3 to encrypt it. To change the encryption state of an existing object, you make a copy of the object and delete the source object. By default, the copy operation encrypts the target only if you explicitly request server-side encryption of the target object. To specify SSE-S3 in the `CopyObjectRequest`, add the following:

```
ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
```

For a working sample of how to copy an object, see Using the AWS SDKs.

The following example uploads an object. In the request, the example directs Amazon S3 to encrypt the object. The example then retrieves object metadata and verifies the encryption method that was used. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SpecifyServerSideEncryptionTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** key name for object created ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            WritingAnObjectAsync().Wait();
        }

        static async Task WritingAnObjectAsync()
        {
            try
            {
                var putRequest = new PutObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName,
                    ContentBody = "sample text",
                    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
                };

                var putResponse = await client.PutObjectAsync(putRequest);

                // Determine the encryption state of an object.
```

```
                GetObjectMetadataRequest metadataRequest = new
 GetObjectMetadataRequest
                {
                    BucketName = bucketName,
                    Key = keyName
                };
                GetObjectMetadataResponse response = await
 client.GetObjectMetadataAsync(metadataRequest);
                ServerSideEncryptionMethod objectEncryption =
 response.ServerSideEncryptionMethod;

                Console.WriteLine("Encryption method used: {0}",
 objectEncryption.ToString());
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered ***. Message:'{0}' when writing
 an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

PHP

This topic shows how to use classes from version 3 of the AWS SDK for PHP to add SSE-S3 to objects that you upload to Amazon S3. For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

To upload an object to Amazon S3, use the Aws\S3\S3Client::putObject() method. To add the `x-amz-server-side-encryption` request header to your upload request, specify the `ServerSideEncryption` parameter with the value `AES256`, as shown in the following code example. For information about server-side encryption requests, see Using the REST API.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;
```

```
$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

// $filepath should be an absolute path to a file on disk.
$filepath = '*** Your File Path ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Upload a file with server-side encryption.
$result = $s3->putObject([
    'Bucket'               => $bucket,
    'Key'                  => $keyname,
    'SourceFile'           => $filepath,
    'ServerSideEncryption' => 'AES256',
]);
```

In response, Amazon S3 returns the `x-amz-server-side-encryption` header with the value of the encryption algorithm that was used to encrypt your object's data.

When you upload large objects by using the multipart upload API operation, you can specify SSE-S3 for the objects that you are uploading, as follows:

- When you're using the low-level multipart upload API operation, specify server-side encryption when you call the Aws\S3\S3Client::createMultipartUpload() method. To add the `x-amz-server-side-encryption` request header to your request, specify the `array` parameter's `ServerSideEncryption` key with the value AES256. For more information about the low-level multipart upload API operation, see Using the AWS SDKs (low-level API).
- When you're using the high-level multipart upload API operation, specify server-side encryption by using the `ServerSideEncryption` parameter of the CreateMultipartUpload API operation. For an example of using the `setOption()` method with the high-level multipart upload API operation, see Uploading an object using multipart upload.

To determine the encryption state of an existing object, retrieve the object metadata by calling the Aws\S3\S3Client::headObject() method as shown in the following PHP code example.

```
require 'vendor/autoload.php';
```

```
use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Check which server-side encryption algorithm is used.
$result = $s3->headObject([
    'Bucket' => $bucket,
    'Key'    => $keyname,
]);
echo $result['ServerSideEncryption'];
```

To change the encryption state of an existing object, make a copy of the object by using the Aws\S3\S3Client::copyObject() method and delete the source object. By default, `copyObject()` does not encrypt the target unless you explicitly request server-side encryption of the destination object by using the `ServerSideEncryption` parameter with the value AES256. The following PHP code example makes a copy of an object and adds server-side encryption to the copied object.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$sourceBucket = '*** Your Source Bucket Name ***';
$sourceKeyname = '*** Your Source Object Key ***';

$targetBucket = '*** Your Target Bucket Name ***';
$targetKeyname = '*** Your Target Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Copy an object and add server-side encryption.
```

```
$s3->copyObject([
    'Bucket'               => $targetBucket,
    'Key'                  => $targetKeyname,
    'CopySource'           => "$sourceBucket/$sourceKeyname",
    'ServerSideEncryption' => 'AES256',
]);
```

For more information, see the following topics:

- AWS SDK for PHP for Amazon S3 Aws\S3\S3Client Class
- AWS SDK for PHP Documentation

Ruby

When using the AWS SDK for Ruby to upload an object, you can specify that the object be stored encrypted at rest with SSE-S3. When you read the object back, it is automatically decrypted.

The following AWS SDK for Ruby Version 3 example demonstrates how to specify that a file uploaded to Amazon S3 be encrypted at rest.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectPutSseWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  def put_object_encrypted(object_content, encryption)
    @object.put(body: object_content, server_side_encryption: encryption)
    true
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't put your content to #{object.key}. Here's why: #{e.message}"
    false
  end
end
```

```
# Example usage:
def run_demo
  bucket_name = "amzn-s3-demo-bucket"
  object_key = "my-encrypted-content"
  object_content = "This is my super-secret content."
  encryption = "AES256"

  wrapper = ObjectPutSseWrapper.new(Aws::S3::Object.new(bucket_name,
 object_content))
  return unless wrapper.put_object_encrypted(object_content, encryption)

  puts "Put your content into #{bucket_name}:#{object_key} and encrypted it with
 #{encryption}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

The following code example demonstrates how to determine the encryption state of an existing object.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectGetEncryptionWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  # Gets the object into memory.
  #
  # @return [Aws::S3::Types::GetObjectOutput, nil] The retrieved object data if
 successful; otherwise nil.
  def object
    @object.get
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't get object #{@object.key}. Here's why: #{e.message}"
  end
end

# Example usage:
```

```
def run_demo
  bucket_name = "amzn-s3-demo-bucket"
  object_key = "my-object.txt"

  wrapper = ObjectGetEncryptionWrapper.new(Aws::S3::Object.new(bucket_name,
 object_key))
  obj_data = wrapper.get_object
  return unless obj_data

  encryption = obj_data.server_side_encryption.nil? ? 'no' :
 obj_data.server_side_encryption
  puts "Object #{object_key} uses #{encryption} encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

If server-side encryption is not used for the object that is stored in Amazon S3, the method returns `null`.

To change the encryption state of an existing object, make a copy of the object and delete the source object. By default, the copy methods do not encrypt the target unless you explicitly request server-side encryption. You can request the encryption of the target object by specifying the `server_side_encryption` value in the option's hash argument, as shown in the following Ruby code example. The code example demonstrates how to copy an object and encrypt the copy with SSE-S3.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectCopyEncryptWrapper
  attr_reader :source_object

  # @param source_object [Aws::S3::Object] An existing Amazon S3 object. This is
 used as the source object for
  #                                       copy actions.
  def initialize(source_object)
    @source_object = source_object
  end

  # Copy the source object to the specified target bucket, rename it with the target
 key, and encrypt it.
  #
```

```
  # @param target_bucket [Aws::S3::Bucket] An existing Amazon S3 bucket where the
 object is copied.
  # @param target_object_key [String] The key to give the copy of the object.
  # @return [Aws::S3::Object, nil] The copied object when successful; otherwise,
 nil.
  def copy_object(target_bucket, target_object_key, encryption)
    @source_object.copy_to(bucket: target_bucket.name, key: target_object_key,
 server_side_encryption: encryption)
    target_bucket.object(target_object_key)
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't copy #{@source_object.key} to #{target_object_key}. Here's why:
 #{e.message}"
  end
end

# Example usage:
def run_demo
  source_bucket_name = "amzn-s3-demo-bucket1"
  source_key = "my-source-file.txt"
  target_bucket_name = "amzn-s3-demo-bucket2"
  target_key = "my-target-file.txt"
  target_encryption = "AES256"

  source_bucket = Aws::S3::Bucket.new(source_bucket_name)
  wrapper = ObjectCopyEncryptWrapper.new(source_bucket.object(source_key))
  target_bucket = Aws::S3::Bucket.new(target_bucket_name)
  target_object = wrapper.copy_object(target_bucket, target_key, target_encryption)
  return unless target_object

  puts "Copied #{source_key} from #{source_bucket_name} to
 #{target_object.bucket_name}:#{target_object.key} and "\
       "encrypted the target with #{target_object.server_side_encryption}
 encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

Using the AWS CLI

To specify SSE-S3 when you upload an object by using the AWS CLI, use the following example.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key object-key-name --server-side-
encryption AES256  --body file path
```

For more information, see put-object in the *AWS CLI reference*. To specify SSE-S3 when you copy an object by using the AWS CLI, see copy-object.

Using CloudFormation

For examples of setting up encryption using CloudFormation, see Create a bucket with default encryption and the Create a bucket by using AWS KMS server-side encryption with an S3 Bucket Key example in the `AWS::S3::Bucket ServerSideEncryptionRule` topic in the *AWS CloudFormation User Guide*.

Using server-side encryption with AWS KMS keys (SSE-KMS)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

Server-side encryption is the encryption of data at its destination by the application or service that receives it.

Amazon S3 automatically enables server-side encryption with Amazon S3 managed keys (SSE-S3) for new object uploads.

Unless you specify otherwise, buckets use SSE-S3 by default to encrypt objects. However, you can choose to configure buckets to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) instead. For more information, see Specifying server-side encryption with AWS KMS (SSE-KMS).

AWS KMS is a service that combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Amazon S3 uses server-side encryption with

AWS KMS (SSE-KMS) to encrypt your S3 object data. Also, when SSE-KMS is requested for the object, the S3 checksum (as part of the object's metadata) is stored in encrypted form. For more information about checksum, see Checking object integrity in Amazon S3.

If you use KMS keys, you can use AWS KMS through the AWS Management Console or the AWS KMS API to do the following:

- Centrally create, view, edit, monitor, enable or disable, rotate, and schedule deletion of KMS keys.
- Define the policies that control how and by whom KMS keys can be used.
- Audit KMS key usage for correct use. Auditing is supported by the AWS KMS API but not by the AWS KMS Console;.

The security controls in AWS KMS can help you meet encryption-related compliance requirements. You can use these KMS keys to protect your data in Amazon S3 buckets. When you use SSE-KMS encryption with an S3 bucket, the AWS KMS keys must be in the same Region as the bucket.

There are additional charges for using AWS KMS keys. For more information, see AWS KMS key concepts in the *AWS Key Management Service Developer Guide* and AWS KMS pricing.

For instructions on allowing IAM users to access KMS-encrypted buckets see My Amazon S3 bucket has default encryption using a custom AWS KMS key. How can I allow users to download from and upload to the bucket? in the AWS re:Post Knowledge Center.

Permissions

To successfully make a `PutObject` request to encrypt an object with an AWS KMS key to Amazon S3, you need `kms:GenerateDataKey` permissions on the key. To download an object encrypted with an AWS KMS key, you need `kms:Decrypt` permissions for the key. To perform a multipart upload to encrypt an object with an AWS KMS key, you must have the `kms:GenerateDataKey` and `kms:Decrypt` permissions for the key.

Important

- Carefully review the permissions that are granted in your KMS key policies. Always restrict customer-managed KMS key policy permissions only to the IAM principals and AWS services that must access the relevant AWS KMS key action. For more information, see Key policies in AWS KMS.

- If a bucket is used as a destination for Amazon S3 server access logging, the destination bucket must use Amazon S3 managed keys (SSE-S3). If the destination bucket uses SSE-KMS default encryption, Amazon S3 might deliver log objects that are encrypted with a key that you can't access. To resolve this, change the destination bucket's default encryption to SSE-S3. For more information, see Enabling Amazon S3 server access logging.

Topics

- AWS KMS keys
- Amazon S3 Bucket Keys
- Requiring server-side encryption
- Encryption context
- Sending requests for AWS KMS encrypted objects
- Specifying server-side encryption with AWS KMS (SSE-KMS)
- Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

AWS KMS keys

When you use server-side encryption with AWS KMS (SSE-KMS), you can use the default AWS managed key, or you can specify a customer managed key that you have already created. AWS KMS supports *envelope encryption*. S3 uses the AWS KMS features for *envelope encryption* to further protect your data. Envelope encryption is the practice of encrypting your plain text data with a data key, and then encrypting that data key with a KMS key. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

If you don't specify a customer managed key, Amazon S3 automatically creates an AWS managed key in your AWS account the first time that you add an object encrypted with SSE-KMS to a bucket. By default, Amazon S3 uses this KMS key for SSE-KMS.

Note

Objects encrypted using SSE-KMS with AWS managed keys can't be shared cross-account. If you need to share SSE-KMS data cross-account, you must use a customer managed key from AWS KMS.

If you want to use a customer managed key for SSE-KMS, create a symmetric encryption customer managed key before you configure SSE-KMS. Then, when you configure SSE-KMS for your bucket, specify the existing customer managed key. For more information about symmetric encryption key, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

Creating a customer managed key gives you more flexibility and control. For example, you can create, rotate, and disable customer managed keys. You can also define access controls and audit the customer managed key that you use to protect your data. For more information about customer managed and AWS managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> When you use server-side encryption with a customer managed key that's stored in an external key store, unlike standard KMS keys, you are responsible for ensuring the availability and durability of your key material. For more information about external key stores and how they shift the shared responsibility model, see External key stores in the *AWS Key Management Service Developer Guide*.

Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (`aws/s3`) from the uploading account is used for encryption and required for decryption.
- AWS managed key (`aws/s3`) can be used as your KMS key for cross-account operations when the uploading and accessing AWS Identity and Access Management (IAM) principals are from the same AWS account.
- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.

- You must specify a key that you (the requester) have been granted `Encrypt` permission to. For more information, see Allow key users to use a KMS key for cryptographic operations in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?

SSE-KMS encryption workflow

If you choose to encrypt your data using an AWS managed key or a customer managed key, AWS KMS and Amazon S3 perform the following envelope encryption actions:

1. Amazon S3 requests a plaintext data key and a copy of the key encrypted under the specified KMS key.
2. AWS KMS generates a data key, encrypts it under the KMS key, and sends both the plaintext data key and the encrypted data key to Amazon S3.
3. Amazon S3 encrypts the data using the data key and removes the plaintext key from memory as soon as possible after use.
4. Amazon S3 stores the encrypted data key as metadata with the encrypted data.

When you request that your data be decrypted, Amazon S3 and AWS KMS perform the following actions:

1. Amazon S3 sends the encrypted data key to AWS KMS in a `Decrypt` request.
2. AWS KMS decrypts the encrypted data key by using the same KMS key and returns the plaintext data key to Amazon S3.
3. Amazon S3 decrypts the encrypted data, using the plaintext data key, and removes the plaintext data key from memory as soon as possible.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS

keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

Auditing SSE-KMS encryption

To identify requests that specify SSE-KMS, you can use the **All SSE-KMS requests** and **% all SSE-KMS requests** metrics in Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can also use the SSE-KMS enabled bucket count and % SSE-KMS enabled buckets to understand the count of buckets that (SSE-KMS) for default bucket encryption. For more information, see Assessing your storage activity and usage with S3 Storage Lens. For a complete list of metrics, see S3 Storage Lens metrics glossary.

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your cryptographic operations, such as GenerateDataKey and Decrypt. CloudTrail supports numerous attribute values for filtering your search, including event name, user name, and event source.

Amazon S3 Bucket Keys

When you configure server-side encryption using AWS KMS (SSE-KMS), you can configure your buckets to use S3 Bucket Keys for SSE-KMS. Using a bucket-level key for SSE-KMS can reduce your AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS.

When you configure a bucket to use an S3 Bucket Key for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create unique data keys for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, further reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations. For more information about using S3 Bucket Keys, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

Requiring server-side encryption

To require server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object (`s3:PutObject`) permission to everyone if the request does not include an `x-amz-server-side-encryption-aws-kms-key-id` header that requests server-side encryption with SSE-KMS.

JSON

```
{
   "Version":"2012-10-17",
   "Id":"PutObjectPolicy",
   "Statement":[{
         "Sid":"DenyObjectsThatAreNotSSEKMS",
         "Effect":"Deny",
         "Principal":"*",
         "Action":"s3:PutObject",
         "Resource":"arn:aws:s3:::amzn-s3-demo-bucket1/*",
         "Condition":{
            "Null":{
               "s3:x-amz-server-side-encryption-aws-kms-key-id":"true"
            }
         }
      }
   ]
}
```

To require that a particular AWS KMS key be used to encrypt the objects in a bucket, you can use the `s3:x-amz-server-side-encryption-aws-kms-key-id` condition key. To specify the KMS key, you must use a key Amazon Resource Name (ARN) that is in the `arn:aws:kms:`*`region`*`:`*`acct-id`*`:key/`*`key-id`* format. AWS Identity and Access Management does not validate if the string for `s3:x-amz-server-side-encryption-aws-kms-key-id` exists.

Note

When you upload an object, you can specify the KMS key by using the `x-amz-server-side-encryption-aws-kms-key-id` header or rely on your default bucket encryption configuration. If your PutObject request specifies `aws:kms` in the `x-amz-server-side-encryption` header, but does not specify the `x-amz-server-side-encryption-aws-kms-key-id` header, then Amazon S3 assumes that you want to use the AWS managed key. Regardless, the AWS KMS key ID that Amazon S3 uses for object encryption must match the AWS KMS key ID in the policy, otherwise Amazon S3 denies the request.

For a complete list of Amazon S3 specific condition keys, see Condition keys for Amazon S3 in the *Service Authorization Reference*.

Encryption context

An *encryption context* is a set of key-value pairs that contains additional contextual information about the data. The encryption context is not encrypted. When an encryption context is specified for an encryption operation, Amazon S3 must specify the same encryption context for the decryption operation. Otherwise, the decryption fails. AWS KMS uses the encryption context as additional authenticated data (AAD) to support authenticated encryption. For more information about the encryption context, see Encryption context in the *AWS Key Management Service Developer Guide*.

By default, Amazon S3 uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair:

- **If you use SSE-KMS without enabling an S3 Bucket Key**, the object ARN is used as the encryption context.

```
arn:aws:s3:::object_ARN
```

- **If you use SSE-KMS and enable an S3 Bucket Key**, the bucket ARN is used as the encryption context. For more information about S3 Bucket Keys, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

```
arn:aws:s3:::bucket_ARN
```

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header in an s3:PutObject request. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context. When it processes your PUT request, Amazon S3 appends the default encryption context of `aws:s3:arn` to the one that you provide.

You can use the encryption context to identify and categorize your cryptographic operations. You can also use the default encryption context ARN value to track relevant requests in AWS CloudTrail by viewing which Amazon S3 ARN was used with which encryption key.

In the `requestParameters` field of a CloudTrail log file, the encryption context looks similar to the following one.

```
"encryptionContext": {
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1/file_name"
}
```

When you use SSE-KMS with the optional S3 Bucket Keys feature, the encryption context value is the ARN of the bucket.

```
"encryptionContext": {
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1"
}
```

Sending requests for AWS KMS encrypted objects

> **Important**
>
> All GET and PUT requests for AWS KMS encrypted objects must be made using Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Requests must also be signed using valid credentials, such as AWS Signature Version 4 (or AWS Signature Version 2).

AWS Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see Authenticating Requests (AWS Signature Version 4) and Signature Version 4 signing process.

> **Important**
>
> If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests. Otherwise, you'll get an HTTP 400 Bad Request error.

- Specifying server-side encryption with AWS KMS (SSE-KMS)
- Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

Specifying server-side encryption with AWS KMS (SSE-KMS)

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can update the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about changing the default encryption configuration for your general purpose buckets, see Configuring default encryption.

When you change the default encryption configuration of your bucket to SSE-KMS, the encryption type of the existing Amazon S3 objects in the bucket is not changed. To change the encryption type of your pre-existing objects after updating the default encryption configuration to SSE-KMS, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects, and Batch Operations calls the respective API operation. You can use the Copy objects action to copy existing objects, which writes them back to the same bucket as SSE-KMS encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and the *AWS Storage Blog* post How to retroactively encrypt existing objects in Amazon S3 using S3 Inventory, Amazon Athena, and S3 Batch Operations.

You can specify SSE-KMS by using the Amazon S3 console, REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

> **Note**
>
> You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see Using multi-Region keys in the *AWS Key Management Service Developer Guide*.

Note

If you want to use a KMS key that's owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

Using the S3 console

This topic describes how to set or change the type of encryption of an object to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) by using the Amazon S3 console.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the AWS CLI or AWS SDKs to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see the section called "Required permissions for S3 API operations". For example policies that grant this permission, see the section called "Identity-based policy examples".
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.

5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.

> **Important**
>
> If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see Quotas in the *AWS Key Management Service Developer Guide*.

7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.

   a. Under **Encryption type**, choose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**.

   b. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
   - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

     For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS

key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.
Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Save changes**.

Note

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of server-side encryption with AWS KMS keys (SSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms`. Amazon S3 confirms that your object is stored using SSE-KMS by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id`
- `x-amz-server-side-encryption-context`
- `x-amz-server-side-encryption-bucket-key-enabled`

Topics

- Amazon S3 REST API operations that support SSE-KMS
- Encryption context (x-amz-server-side-encryption-context)
- AWS KMS key ID (x-amz-server-side-encryption-aws-kms-key-id)
- S3 Bucket Keys (x-amz-server-side-encryption-aws-bucket-key-enabled)

Amazon S3 REST API operations that support SSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- PutObject – When you upload data by using the PUT API operation, you can specify these request headers.
- CopyObject – When you copy an object, you have both a source object and a target object. When you pass SSE-KMS headers with the `CopyObject` operation, they're applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object isn't encrypted unless you explicitly request server-side encryption.
- POST Object – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- CreateMultipartUpload – When you upload large objects by using the multipart upload API operation, you can specify these headers. You specify these headers in the `CreateMultipartUpload` request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored by using server-side encryption.

- PutObject
- CopyObject
- POST Object
- CreateMultipartUpload
- UploadPart
- UploadPartCopy
- CompleteMultipartUpload

- GetObject
- HeadObject

> **Important**
>
> - All GET and PUT requests for an object protected by AWS KMS fail if you don't make these requests by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
> - If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 BadRequest error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair. If you use SSE-KMS without enabling an S3 Bucket Key, you use the object ARN as your encryption context; for example, `arn:aws:s3:::`*`object_ARN`*. However, if you use SSE-KMS and enable an S3 Bucket Key, you use the bucket ARN for your encryption context; for example, `arn:aws:s3:::`*`bucket_ARN`*.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context isn't encrypted, make sure it doesn't include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see Encryption context. For general information about the encryption context, see AWS Key Management Service Concepts - Encryption context in the *AWS Key Management Service Developer Guide*.

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-`

`side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (`aws/s3`) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys (`x-amz-server-side-encryption-aws-bucket-key-enabled`)

You can use the `x-amz-server-side-encryption-aws-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level. S3 Bucket Keys reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-bucket-key-enabled` header, your object uses the S3 Bucket Key settings for the destination bucket to encrypt your object. For more information, see Configuring an S3 Bucket Key at the object level.

Using the AWS CLI

To use the following example AWS CLI commands, replace the *`user input placeholders`* with your own information.

When you upload a new object or copy an existing object, you can specify the use of server-side encryption with AWS KMS keys to encrypt your data. To do this, add the `--server-side-encryption aws:kms` header to the request. Use the `--ssekms-key-id` *`example-key-id`* to add your customer managed AWS KMS key that you created. If you specify `--server-side-encryption aws:kms`, but don't provide an AWS KMS key ID, Amazon S3 will use an AWS managed key.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms --ssekms-key-id example-key-id --body filepath
```

You can additionally enable or disable Amazon S3 Bucket Keys on your PUT or COPY operations by adding `--bucket-key-enabled` or `--no-bucket-key-enabled`. Amazon S3 Bucket Keys can reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-
side-encryption aws:kms --bucket-key-enabled --body filepath
```

You can encrypt an unencrypted object to use SSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket amzn-s3-demo-bucket --key example-object-key --
body filepath --bucket amzn-s3-demo-bucket --key example-object-key --sse aws:kms --
sse-kms-key-id example-key-id --body filepath
```

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use AWS KMS keys for server-side encryption. The following examples show how to use SSE-KMS with the AWS SDKs for Java and .NET. For information about other SDKs, see Sample code and libraries on the AWS Developer Center.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

`CopyObject` operation

When copying objects, you add the same request properties (`ServerSideEncryptionMethod` and `ServerSideEncryptionKeyManagementServiceKeyId`) to request Amazon S3 to use an AWS KMS key. For more information about copying objects, see Copying, moving, and renaming objects.

PUT operation

Java

When uploading an object by using the AWS SDK for Java, you can request Amazon S3 to use an AWS KMS key by adding the `SSEAwsKeyManagementParams` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,
   keyName, file).withSSEAwsKeyManagementParams(new SSEAwsKeyManagementParams());
```

In this case, Amazon S3 uses the AWS managed key (`aws/s3`). For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS). You can optionally create a symmetric encryption KMS key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,
   keyName, file).withSSEAwsKeyManagementParams(new
 SSEAwsKeyManagementParams(keyID));
```

For more information about creating customer managed keys, see Programming the AWS KMS API in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see Uploading objects.
- For multipart uploads that use the high-level or low-level multipart upload API operations, see Uploading an object using multipart upload.

.NET

When uploading an object by using the AWS SDK for .NET, you can request Amazon S3 to use an AWS KMS key by adding the `ServerSideEncryptionMethod` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest
 {
```

```
    BucketName = amzn-s3-demo-bucket,
    Key = keyName,
    // other properties
    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS
};
```

In this case, Amazon S3 uses the AWS managed key. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS). You can optionally create your own symmetric encryption customer managed key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest1 = new PutObjectRequest
{
  BucketName = amzn-s3-demo-bucket,
  Key = keyName,
  // other properties
  ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS,
  ServerSideEncryptionKeyManagementServiceKeyId = keyId
};
```

For more information about creating customer managed keys, see Programming the AWS KMS API in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see Uploading objects.
- For multipart uploads that use the high-level or low-level multipart upload API operations, see Uploading an object using multipart upload.

Presigned URLs

Java

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
ClientConfiguration clientConfiguration = new ClientConfiguration();
```

```
clientConfiguration.setSignerOverride("AWSS3V4SignerType");
AmazonS3Client s3client = new AmazonS3Client(
        new ProfileCredentialsProvider(), clientConfiguration);
...
```

For a code example, see Sharing objects with presigned URLs.

.NET

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
AWSConfigs.S3Config.UseSignatureVersion4 = true;
```

For a code example, see Sharing objects with presigned URLs.

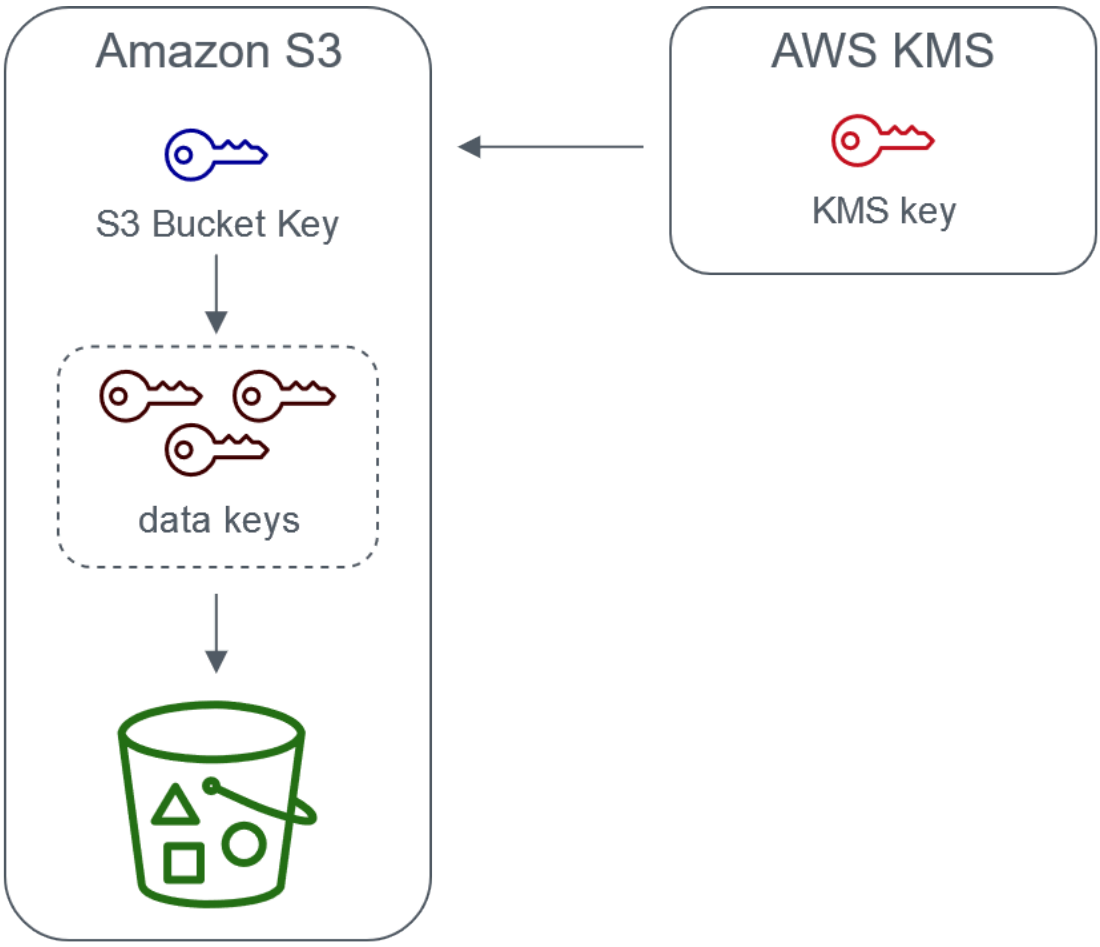
Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). Using a bucket-level key for SSE-KMS can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. With a few clicks in the AWS Management Console, and without any changes to your client applications, you can configure your bucket to use an S3 Bucket Key for SSE-KMS encryption on new objects.

> **Note**
>
> S3 Bucket Keys aren't supported for dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS).

S3 Bucket Keys for SSE-KMS

Workloads that access millions or billions of objects encrypted with SSE-KMS can generate large volumes of requests to AWS KMS. When you use SSE-KMS to protect your data without an S3 Bucket Key, Amazon S3 uses an individual AWS KMS data key for every object. In this case, Amazon S3 makes a call to AWS KMS every time a request is made against a KMS-encrypted object. For information about how SSE-KMS works, see Using server-side encryption with AWS KMS keys (SSE-KMS).



When you configure your bucket to use an S3 Bucket Key for SSE-KMS, AWS generates a short-lived bucket-level key from AWS KMS, then temporarily keeps it in S3. This bucket-level key will create data keys for new objects during its lifecycle. S3 Bucket Keys are used for a limited time period within Amazon S3, reducing the need for S3 to make requests to AWS KMS to complete encryption operations. This reduces traffic from S3 to AWS KMS, allowing you to access AWS KMS-encrypted objects in Amazon S3 at a fraction of the previous cost.

Unique bucket-level keys are fetched at least once per requester to ensure that the requester's access to the key is captured in an AWS KMS CloudTrail event. Amazon S3 treats callers as different requesters when they use different roles or accounts, or the same role with different scoping policies. AWS KMS request savings reflect the number of requesters, request patterns, and relative age of the objects requested. For example, a fewer number of requesters, requesting multiple objects in a limited time window, and encrypted with the same bucket-level key, results in greater savings.

> **Note**
>
> Using S3 Bucket Keys allows you to save on AWS KMS request costs by decreasing your requests to AWS KMS for `Encrypt`, `GenerateDataKey`, and `Decrypt` operations through the use of a bucket-level key. By design, subsequent requests that take advantage of this bucket-level key do not result in AWS KMS API requests or validate access against the AWS KMS key policy.

When you configure an S3 Bucket Key, objects that are already in the bucket do not use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see Configuring an S3 Bucket Key at the object level.

Amazon S3 will only share an S3 Bucket Key for objects encrypted by the same AWS KMS key. S3 Bucket Keys are compatible with KMS keys created by AWS KMS, imported key material, and key material backed by custom key stores.

Server-side encryption with AWS Key Management service using an S3 Bucket Key

Configuring S3 Bucket Keys

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects through the Amazon S3 console, AWS SDKs, AWS CLI, or REST API. With S3 Bucket Keys enabled on your bucket, objects uploaded with a different specified SSE-KMS key will use their own S3 Bucket Keys. Regardless of your S3 Bucket Key setting, you can include the `x-amz-server-side-encryption-bucket-key-enabled` header with a `true` or `false` value in your request, to override the bucket setting.

Before you configure your bucket to use an S3 Bucket Key, review Changes to note before enabling an S3 Bucket Key.

Configuring an S3 Bucket Key using the Amazon S3 console

When you create a new bucket, you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also configure an existing bucket to use an S3 Bucket Key for SSE-KMS on new objects by updating your bucket properties.

For more information, see Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects.

REST API, AWS CLI, and AWS SDK support for S3 Bucket Keys

You can use the REST API, AWS CLI, or AWS SDK to configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also enable an S3 Bucket Key at the object level.

For more information, see the following:

- Configuring an S3 Bucket Key at the object level
- Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects

The following API operations support S3 Bucket Keys for SSE-KMS:

- PutBucketEncryption
  - `ServerSideEncryptionRule` accepts the `BucketKeyEnabled` parameter for enabling and disabling an S3 Bucket Key.
- GetBucketEncryption
  - `ServerSideEncryptionRule` returns the settings for `BucketKeyEnabled`.
- PutObject, CopyObject, CreateMultipartUpload, and POST Object
  - The `x-amz-server-side-encryption-bucket-key-enabled` request header enables or disables an S3 Bucket Key at the object level.
- HeadObject, GetObject, UploadPartCopy, UploadPart, and CompleteMultipartUpload
  - The `x-amz-server-side-encryption-bucket-key-enabled` response header indicates if an S3 Bucket Key is enabled or disabled for an object.

Working with CloudFormation

In CloudFormation, the `AWS::S3::Bucket` resource includes an encryption property called `BucketKeyEnabled` that you can use to enable or disable an S3 Bucket Key.

For more information, see Using CloudFormation.

Changes to note before enabling an S3 Bucket Key

Before you enable an S3 Bucket Key, note the following related changes:

IAM or AWS KMS key policies

If your existing AWS Identity and Access Management (IAM) policies or AWS KMS key policies use your object Amazon Resource Name (ARN) as the encryption context to refine or limit access to your KMS key, these policies won't work with an S3 Bucket Key. S3 Bucket Keys use the bucket ARN as encryption context. Before you enable an S3 Bucket Key, update your IAM policies or AWS KMS key policies to use your bucket ARN as the encryption context.

For more information about the encryption context and S3 Bucket Keys, see Encryption context.

CloudTrail events for AWS KMS

After you enable an S3 Bucket Key, your AWS KMS CloudTrail events log your bucket ARN instead of your object ARN. Additionally, you see fewer KMS CloudTrail events for SSE-KMS objects in your logs. Because key material is time-limited in Amazon S3, fewer requests are made to AWS KMS.

Using an S3 Bucket Key with replication

You can use S3 Bucket Keys with Same-Region Replication (SRR) and Cross-Region Replication (CRR).

When Amazon S3 replicates an encrypted object, it generally preserves the encryption settings of the replica object in the destination bucket. However, if the source object is not encrypted and your destination bucket uses default encryption or an S3 Bucket Key, Amazon S3 encrypts the object with the destination bucket's configuration.

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).

Example 1 – Source object uses S3 Bucket Keys; destination bucket uses default encryption

If your source object uses an S3 Bucket Key but your destination bucket uses default encryption with SSE-KMS, the replica object maintains its S3 Bucket Key encryption settings in the destination bucket. The destination bucket still uses default encryption with SSE-KMS.

Example 2 – Source object is not encrypted; destination bucket uses an S3 Bucket Key with SSE-KMS

If your source object is not encrypted and the destination bucket uses an S3 Bucket Key with SSE-KMS, the replica object is encrypted by using an S3 Bucket Key with SSE-KMS in the destination bucket. This results in the `ETag` of the source object being different from the `ETag` of the replica object. You must update applications that use the `ETag` to accommodate for this difference.

Working with S3 Bucket Keys

For more information about enabling and working with S3 Bucket Keys, see the following sections:

- Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects
- Configuring an S3 Bucket Key at the object level
- Viewing the settings for an S3 Bucket Key

Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects

When you configure server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. S3 Bucket Keys decrease the request traffic from Amazon S3 to AWS KMS and reduce the cost of SSE-KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects by using the Amazon S3 console, REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or CloudFormation. If you want to enable or disable an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see Configuring an S3 Bucket Key at the object level and Using Batch Operations to enable S3 Bucket Keys for SSE-KMS.

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket Amazon Resource Name (ARN) and not the object ARN, for example, `arn:aws:s3:::`*`bucket_ARN`*. You need to update your IAM policies to use the bucket ARN for the encryption context. For more information, see S3 Bucket Keys and replication.

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).

Prerequisites

Before you configure your bucket to use an S3 Bucket Key, review Changes to note before enabling an S3 Bucket Key.

Using the S3 console

In the S3 console, you can enable or disable an S3 Bucket Key for a new or existing bucket. Objects in the S3 console inherit their S3 Bucket Key setting from the bucket configuration. When you enable an S3 Bucket Key for your bucket, new objects that you upload to the bucket use an S3 Bucket Key for SSE-KMS.

Uploading, copying, or modifying objects in buckets that have an S3 Bucket Key enabled

If you upload, modify, or copy an object in a bucket that has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object might be updated to align with the bucket configuration.

If an object already has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object don't change when you copy or modify the object. However, if you modify or copy an object that doesn't have an S3 Bucket Key enabled, and the destination bucket has an S3 Bucket Key configuration, the object inherits the destination bucket's S3 Bucket Key settings. For example, if your source object doesn't have an S3 Bucket Key enabled but the destination bucket has S3 Bucket Key enabled, an S3 Bucket Key is enabled for the object.

To enable an S3 Bucket Key when you create a new bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. Enter your bucket name, and choose your AWS Region.
5. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
6. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

  For more information about creating an AWS KMS key, see Creating Keys in the *AWS Key Management Service Developer Guide*.

7. Under **Bucket Key**, choose **Enable**.
8. Choose **Create bucket**.

   Amazon S3 creates your bucket with an S3 Bucket Key enabled. New objects that you upload to the bucket will use an S3 Bucket Key.

   To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

To enable an S3 Bucket Key for an existing bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
7. Under **AWS KMS key**, do one of the following to choose your KMS key:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
   - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see Creating Keys in the *AWS Key Management Service Developer Guide*.

8. Under **Bucket Key**, choose **Enable**.
9. Choose **Save changes**.

Amazon S3 enables an S3 Bucket Key for new objects added to your bucket. Existing objects don't use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see Configuring an S3 Bucket Key at the object level.

To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

Using the REST API

You can use PutBucketEncryption to enable or disable an S3 Bucket Key for your bucket. To configure an S3 Bucket Key with `PutBucketEncryption`, use the ServerSideEncryptionRule data type, which includes default encryption with SSE-KMS. You can also optionally use a customer managed key by specifying the KMS key ID for the customer managed key.

For more information and example syntax, see PutBucketEncryption.

Using the AWS SDK for Java

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

ServerSideEncryptionByDefault serverSideEncryptionByDefault = new
 ServerSideEncryptionByDefault()
    .withSSEAlgorithm(SSEAlgorithm.KMS);
ServerSideEncryptionRule rule = new ServerSideEncryptionRule()
    .withApplyServerSideEncryptionByDefault(serverSideEncryptionByDefault)
    .withBucketKeyEnabled(true);
ServerSideEncryptionConfiguration serverSideEncryptionConfiguration =
```

```
    new ServerSideEncryptionConfiguration().withRules(Collections.singleton(rule));

SetBucketEncryptionRequest setBucketEncryptionRequest = new
 SetBucketEncryptionRequest()
    .withServerSideEncryptionConfiguration(serverSideEncryptionConfiguration)
    .withBucketName(bucketName);

s3client.setBucketEncryption(setBucketEncryptionRequest);
```

Using the AWS CLI

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS CLI. Replace the *`user input placeholders`* with your own information.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
        "Rules": [
            {
                "ApplyServerSideEncryptionByDefault": {
                    "SSEAlgorithm": "aws:kms",
                    "KMSMasterKeyID": "KMS-Key-ARN"
                },
                "BucketKeyEnabled": true
            }
        ]
    }'
```

Using CloudFormation

For more information about configuring an S3 Bucket Key with CloudFormation, see AWS::S3::Bucket ServerSideEncryptionRule in the *AWS CloudFormation User Guide*.

Configuring an S3 Bucket Key at the object level

When you perform a PUT or COPY operation using the REST API, AWS SDKs, or AWS CLI, you can enable or disable an S3 Bucket Key at the object level by adding the `x-amz-server-side-encryption-bucket-key-enabled` request header with a `true` or `false` value. S3 Bucket Keys reduce the cost of server-side encryption using AWS Key Management Service (AWS KMS) (SSE-KMS) by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

When you configure an S3 Bucket Key for an object using a PUT or COPY operation, Amazon S3 only updates the settings for that object. The S3 Bucket Key settings for the destination bucket do not change. If you submit a PUT or COPY request for a KMS-encrypted object into a bucket with S3 Bucket Keys enabled, your object level operation will automatically use S3 Bucket Keys unless you disable the keys in the request header. If you don't specify an S3 Bucket Key for your object, Amazon S3 applies the S3 Bucket Key settings for the destination bucket to the object.

Prerequisite:

Before you configure your object to use an S3 Bucket Key, review Changes to note before enabling an S3 Bucket Key.

Topics

- Amazon S3 Batch Operations
- Using the REST API
- Using the AWS SDK for Java (PutObject)
- Using the AWS CLI (PutObject)

Amazon S3 Batch Operations

To encrypt your existing Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation.

You can use the S3 Batch Operations Copy operation to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see Performing object operations in bulk with Batch Operations and Encrypting objects with Amazon S3 Batch Operations.

Using the REST API

When you use SSE-KMS, you can enable an S3 Bucket Key for an object by using the following API operations:

- PutObject – When you upload an object, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level.

- CopyObject – When you copy an object and configure SSE-KMS, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key for your object.
- POST Object – When you use a POST operation to upload an object and configure SSE-KMS, you can use the `x-amz-server-side-encryption-bucket-key-enabled` form field to enable or disable an S3 Bucket Key for your object.
- CreateMultipartUpload – When you upload large objects by using the `CreateMultipartUpload` API operation and configure SSE-KMS, you can use the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key for your object.

To enable an S3 Bucket Key at the object level, include the `x-amz-server-side-encryption-bucket-key-enabled` request header. For more information about SSE-KMS and the REST API, see Using the REST API.

Using the AWS SDK for Java (PutObject)

You can use the following example to configure an S3 Bucket Key at the object level using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

String bucketName = "amzn-s3-demo-bucket1";
String keyName = "key name for object";
String contents = "file contents";

PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName, keyName,
 contents)
    .withBucketKeyEnabled(true);

s3client.putObject(putObjectRequest);
```

Using the AWS CLI (PutObject)

You can use the following AWS CLI example to configure an S3 Bucket Key at the object level as part of a `PutObject` request.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object key name --server-side-encryption aws:kms --bucket-key-enabled --body filepath
```

Viewing the settings for an S3 Bucket Key

You can view the settings for an S3 Bucket Key at the bucket or object level by using the Amazon S3 console, REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

S3 Bucket Keys decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of server-side encryption using AWS Key Management Service (SSE-KMS). For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.

To view the S3 Bucket Key settings for a bucket or an object that has inherited S3 Bucket Key settings from the bucket configuration, you need permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see GetBucketEncryption in the *Amazon Simple Storage Service API Reference*.

Using the S3 console

In the S3 console, you can view the S3 Bucket Key settings for your bucket or object. S3 Bucket Key settings are inherited from the bucket configuration unless the source objects already has an S3 Bucket Key configured.

Objects and folders in the same bucket can have different S3 Bucket Key settings. For example, if you upload an object using the REST API and enable an S3 Bucket Key for the object, the object retains its S3 Bucket Key setting in the destination bucket, even if S3 Bucket Key is disabled in the destination bucket. As another example, if you enable an S3 Bucket Key for an existing bucket, objects that are already in the bucket do not use an S3 Bucket Key. However, new objects have an S3 Bucket Key enabled.

To view the S3 Bucket Key setting for your bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose **Properties**.
5. In the **Default encryption** section, under **Bucket Key**, you see the S3 Bucket Key setting for your bucket.

   If you can't see the S3 Bucket Key setting, you might not have permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see GetBucketEncryption in the *Amazon Simple Storage Service API Reference*.

To view the S3 Bucket Key setting for your object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
3. In the **Objects** list, choose your object name.
4. On the **Details** tab, under **Server-side encryption settings**, choose **Edit**.

   Under **Bucket Key**, you see the S3 Bucket Key setting for your object. You cannot edit this setting.

Using the AWS CLI

To return bucket-level S3 Bucket Key settings

To use this example, replace each *user input placeholder* with your own information.

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
```

For more information, see get-bucket-encryption in the *AWS CLI Command Reference*.

To return object-level S3 Bucket Key settings

To use this example, replace each *user input placeholder* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-bucket1 --key my_images.tar.bz2
```

For more information, see head-object in the *AWS CLI Command Reference*.

Using the REST API

To return bucket-level S3 Bucket Key settings

To return encryption information for a bucket, including the settings for an S3 Bucket Key, use the `GetBucketEncryption` operation. S3 Bucket Key settings are returned in the response body in the `ServerSideEncryptionConfiguration` element with the `BucketKeyEnabled` setting. For more information, see GetBucketEncryption in the *Amazon S3 API Reference*.

To return object-level settings for an S3 Bucket Key

To return the S3 Bucket Key status for an object, use the `HeadObject` operation. `HeadObject` returns the `x-amz-server-side-encryption-bucket-key-enabled` response header to show whether an S3 Bucket Key is enabled or disabled for the object. For more information, see HeadObject in the *Amazon S3 API Reference*.

The following API operations also return the `x-amz-server-side-encryption-bucket-key-enabled` response header if an S3 Bucket Key is configured for an object:

- PutObject
- PostObject
- CopyObject
- CreateMultipartUpload
- UploadPartCopy
- UploadPart
- CompleteMultipartUpload
- GetObject

Using dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

Using dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. DSSE-KMS helps you more easily fulfill compliance standards that require you to apply multilayer encryption to your data and have full control of your encryption keys.

The "dual" in DSSE-KMS refers to two independent layers of AES-256 encryption that are applied to your data:

- *First layer:* Your data is encrypted using a unique data encryption key (DEK) generated by AWS KMS
- *Second layer:* The already-encrypted data is encrypted again using a separate AES-256 encryption key managed by Amazon S3

This differs from standard SSE-KMS, which applies only a single layer of encryption. The dual-layer approach provides enhanced security by ensuring that even if one encryption layer were compromised, your data would remain protected by the second layer. This additional security comes with increased processing overhead and AWS KMS API calls, which accounts for the higher cost compared to standard SSE-KMS. For more information about DSSE-KMS pricing, see AWS KMS key concepts in the AWS Key Management Service Developer Guide and AWS KMS pricing.

When you use DSSE-KMS with an Amazon S3 bucket, the AWS KMS keys must be in the same Region as the bucket. Also, when DSSE-KMS is requested for the object, the S3 checksum that's part of the object's metadata is stored in encrypted form. For more information about checksums, see Checking object integrity in Amazon S3.

> **Note**
>
> S3 Bucket Keys aren't supported for DSSE-KMS.

The key differences between DSSE-KMS and standard SSE-KMS are:

- **Encryption layers:** DSSE-KMS applies two independent layers of AES-256 encryption, while standard SSE-KMS applies one layer
- **Security:** DSSE-KMS provides enhanced protection against potential encryption vulnerabilities
- **Compliance:** DSSE-KMS helps meet regulatory requirements that mandate multilayer encryption
- **Performance:** DSSE-KMS has slightly higher latency due to additional encryption processing
- **Cost:** DSSE-KMS incurs higher charges due to increased computational overhead and additional AWS KMS operations

Requiring dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

To require dual-layer server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object

(`s3:PutObject`) permission to everyone if the request does not include an `x-amz-server-side-encryption` header that requests server-side encryption with DSSE-KMS.

JSON

```
{
            "Version":"2012-10-17",
            "Id": "PutObjectPolicy",
            "Statement": [{
                  "Sid": "DenyUnEncryptedObjectUploads",
                  "Effect": "Deny",
                  "Principal": {
                      "AWS": "arn:aws:iam::111122223333:root"
                  },
                  "Action": "s3:PutObject",
                  "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
                  "Condition": {
                     "StringNotEquals": {
                        "s3:x-amz-server-side-encryption": "aws:kms:dsse"
                     }
                  }
               }
            ]
         }
```

Topics

- Specifying dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

Specifying dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

You can apply encryption when you are either uploading a new object or copying an existing object.

You can specify DSSE-KMS by using the Amazon S3 console, Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

> **Note**
>
> You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the

multi-Region features of the key. For more information, see Using multi-Region keys in the *AWS Key Management Service Developer Guide*.

Note

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see Creating KMS keys that other accounts can use in the *AWS Key Management Service Developer Guide*.

Using the S3 console

This section describes how to set or change the type of encryption of an object to use dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) by using the Amazon S3 console.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the AWS CLI or AWS SDKs to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see the section called "Required permissions for S3 API operations". For example policies that grant this permission, see the section called "Identity-based policy examples".
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.

    a. Under **Encryption type**, choose **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**.

    b. Under **AWS KMS key**, do one of the following to choose your KMS key:

    - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

      Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
    - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
    - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

      For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

> **Important**
>
> You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you

must first have permission to use the key, and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see Identifying asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

8. For **Bucket Key**, choose **Disable**. S3 Bucket Keys aren't supported for DSSE-KMS.
9. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
10. Choose **Save changes**.

Note

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms:dsse`. Amazon S3 confirms that your object is stored with DSSE-KMS encryption by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms:dsse`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id: SSEKMSKeyId`
- `x-amz-server-side-encryption-context: SSEKMSEncryptionContext`

Topics

- Amazon S3 REST API operations that support DSSE-KMS
- Encryption context (x-amz-server-side-encryption-context)
- AWS KMS key ID (x-amz-server-side-encryption-aws-kms-key-id)

Amazon S3 REST API operations that support DSSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- PutObject – When you upload data by using the PUT API operation, you can specify these request headers.
- CopyObject – When you copy an object, you have both a source object and a target object. When you pass DSSE-KMS headers with the `CopyObject` operation, they are applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.
- POST Object – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- CreateMultipartUpload – When you upload large objects by using a multipart upload, you can specify these headers in the `CreateMultipartUpload` request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored with server-side encryption.

- PutObject
- CopyObject
- POST Object
- CreateMultipartUpload
- UploadPart
- UploadPartCopy
- CompleteMultipartUpload
- GetObject
- HeadObject

Important

- All GET and PUT requests for an object that's protected by AWS KMS fail if you don't make them by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
- If your object uses DSSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 (Bad Request) error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms:dsse`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object's Amazon Resource Name (ARN) as the encryption context pair; for example, `arn:aws:s3:::`*`object_ARN`*.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see Encryption context. For general information about the encryption context, see AWS Key Management Service Concepts - Encryption context in the *AWS Key Management Service Developer Guide*.

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms:dsse` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (`aws/s3`) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

> **Important**
>
> When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see Symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

Using the AWS CLI

When you upload a new object or copy an existing object, you can specify the use of DSSE-KMS to encrypt your data. To do this, add the `--server-side-encryption aws:kms:dsse` parameter to the request. Use the `--ssekms-key-id` *`example-key-id`* parameter to add your customer managed AWS KMS key that you created. If you specify `--server-side-encryption aws:kms:dsse`, but do not provide an AWS KMS key ID, then Amazon S3 will use the AWS managed key (`aws/s3`).

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms:dsse --ssekms-key-id example-key-id --body filepath
```

You can encrypt an unencrypted object to use DSSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket amzn-s3-demo-bucket --key example-object-key --copy-source amzn-s3-demo-bucket/example-object-key --server-side-encryption aws:kms:dsse --ssekms-key-id example-key-id
```

Using server-side encryption with customer-provided keys (SSE-C)

Server-side encryption is about protecting data at rest. Server-side encryption encrypts only the object data, not the object metadata. You can use server-side encryption with customer-provided keys (SSE-C) in your general purpose buckets to encrypt your data with your own encryption keys. With the encryption key that you provide as part of your request, Amazon S3 manages data encryption as it writes to disks and data decryption when you access your objects. Therefore, you don't need to maintain any code to perform data encryption and decryption. The only thing that you need to do is manage the encryption keys that you provide.

Starting April 2026, SSE-C is disabled by default for all new general purpose buckets and existing buckets in accounts with no SSE-C encrypted objects. Most modern workloads use server-side encryption with Amazon S3 managed keys (SSE-S3) or AWS KMS keys (SSE-KMS) instead, because

SSE-C requires you to provide the encryption key with every request, making it impractical to share access with other users, roles, or AWS services that operate on your data. To learn more about SSE-KMS, see the section called "KMS keys stored in AWS KMS (SSE-KMS)".

If your workload requires SSE-C, you must explicitly enable it by setting `BlockedEncryptionTypes` to `NONE` in your bucket's default encryption configuration using the `PutBucketEncryption` API. While SSE-C is blocked, any `PutObject`, `CopyObject`, `PostObject`, Multipart Upload, or replication request that specifies SSE-C encryption is rejected with an HTTP 403 `AccessDenied` error. To learn more, see the section called "Blocking or unblocking SSE-C".

There are no additional charges for using SSE-C. However, requests to configure and use SSE-C incur standard Amazon S3 request charges. For information about pricing, see Amazon S3 pricing.

> **Important**
>
> Amazon Simple Storage Service now applies a new default bucket security setting that automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. In April 2026, Amazon S3 deployed an update so all new general purpose buckets have SSE-C encryption disabled for all new write requests. For existing buckets in AWS accounts with no SSE-C encrypted objects, Amazon S3 also disabled SSE-C for all new write requests. With this change, applications that need SSE-C encryption must deliberately enable SSE-C by using the PutBucketEncryption API operation after creating a new bucket. For more information about this change, see Default SSE-C setting for new buckets FAQ.

Considerations before using SSE-C

- S3 never stores the encryption key when you use SSE-C. You must supply the encryption key every time you want anyone to download your SSE-C encrypted data from S3.
  - You manage a mapping of which encryption key was used to encrypt which object. You are responsible for tracking which encryption key you provided for which object. That also means if you lose the encryption key, you lose the object.
  - Because you manage encryption keys on the client side, you manage any additional safeguards, such as key rotation, on the client side.
  - This design can make it difficult to share your SSE-C key with other users, roles, or AWS services that need to operate on your data. Due to the widespread support for SSE-KMS across

AWS, most modern workloads do not use SSE-C because it lacks the flexibility of SSE-KMS. To learn more about SSE-KMS, see Using server-side encryption with AWS KMS keys (SSE-KMS).

  - This means that objects encrypted with SSE-C cannot be natively decrypted by AWS managed services.

- You must use HTTPS when specifying SSE-C headers on your requests.
  - Amazon S3 rejects any requests made over HTTP when using SSE-C. For security considerations, we recommend that you consider any key that you erroneously send over HTTP to be compromised. Discard the key and rotate as appropriate.
- If your bucket is versioning-enabled, each object version that you upload can have its own encryption key. You are responsible for tracking which encryption key was used for which object version.
- SSE-C is not supported in the Amazon S3 Console. You cannot use the Amazon S3 console to upload an object and specify SSE-C encryption. You also cannot use the console to update (for example, change the storage class or add metadata) an existing object stored using SSE-C.
- SSE-C is blocked by default for new buckets. You must explicitly enable SSE-C using the `PutBucketEncryption` API before you can upload objects with SSE-C encryption. For more information, see the section called "Blocking or unblocking SSE-C".

Specifying server-side encryption with customer-provided keys (SSE-C)

Server-side encryption with customer-provided keys (SSE-C) is disabled by default for new general purpose buckets. Before you can upload objects using SSE-C, you must enable it by setting `BlockedEncryptionTypes` to `NONE` in your bucket's default encryption configuration. For more information, see Blocking or unblocking SSE-C for a general purpose bucket.

Once SSE-C is enabled for your bucket, you can use SSE-C in your upload requests by passing the required headers. See Amazon S3 actions that support writing data with SSE-C, and make sure to include the S3 API headers required for SSE-C object encryption and decryption requests.

When you upload an object specifying SSE-C, Amazon S3 uses the encryption key that you provide to apply AES-256 encryption to your data. Amazon S3 then removes the encryption key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. Amazon S3 first verifies that the encryption key that you provided matches, and then it decrypts the object before returning the object data to you.

Before using SSE-C, make sure you have reviewed the Considerations before using SSE-C.

> **Note**
>
> Amazon S3 does not store the encryption key that you provide. Instead, it stores a randomly salted Hash-based Message Authentication Code (HMAC) value of the encryption key to validate future requests. The salted HMAC value cannot be used to derive the value of the encryption key or to decrypt the contents of the encrypted object. That means if you lose the encryption key, you lose the object.

- Using the AWS SDKs to specify SSE-C for PUT, GET, Head, and Copy operations
- Using the AWS SDKs to specify SSE-C for multipart uploads

SSE-C Actions and Required Headers

Specifying SSE-C on supported S3 APIs requires passing specific request parameters.

> **Note**
>
> The `PutBucketEncryption` API does not support setting SSE-C as a default encryption method for a bucket, objects won't automatically use SSE-C. SSE-C is an object-level encryption method where you provide the encryption key with each upload or download request. Amazon S3 uses this key to encrypt or decrypt the object during the request and then discards the key.

However, you do use `PutBucketEncryption` to control whether SSE-C uploads are allowed for the bucket via the `BlockedEncryptionTypes` parameter. By default, new buckets have SSE-C blocked, you must set `BlockedEncryptionTypes` to `NONE` to permit SSE-C uploads.

Amazon S3 actions that support writing data with SSE-C

You can request server-side encryption with customer provided keys (SSE-C) when writing objects to a general purpose bucket by using the following API operations or actions:

- CopyObject
- CreateMultipartUpload
- CompleteMultipartUpload
- POST Object
- PutObject
- UploadPart
- UploadPartCopy

Note

S3 Replication supports objects that are encrypted with SSE-C. For more information about replicating encrypted objects, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).

S3 API headers required for SSE-C object encryption and decryption requests

You must provide the following three API headers to encrypt or decrypt objects with SSE-C:

- `x-amz-server-side-encryption-customer-algorithm` Use this header to specify the encryption algorithm. The header value must be AES256.
- `x-amz-server-side-encryption-customer-key` Use this header to provide the 256-bit, base64-encoded encryption key for Amazon S3 to use to encrypt or decrypt your data.
- `x-amz-server-side-encryption-customer-key-MD5` Use this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321. Amazon S3

uses this header for a message integrity check to ensure that the encryption key was transmitted without error.

S3 API headers required for requests to copy source objects encrypted with SSE-C

You must provide the following three API headers to copy source objects encrypted with SSE-C:

- `x-amz-copy-source-server-side-encryption-customer-algorithm` Include this header to specify the algorithm Amazon S3 should use to decrypt the source object. This value must be AES256.
- `x-amz-copy-source-server-side-encryption-customer-key` Include this header to provide the base64-encoded encryption key for Amazon S3 to use to decrypt the source object. This encryption key must be the one that you provided Amazon S3 when you created the source object. Otherwise, Amazon S3 cannot decrypt the object.
- `x-amz-copy-source-server-side-encryption-customer-key-MD5` Include this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321.

Example bucket policy to enforce SSE-C encryption

To require SSE-C for all objects written to an Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies upload object (`s3:PutObject`) permissions for all requests that don't include the `x-amz-server-side-encryption-customer-algorithm` header requesting SSE-C.

```
{
"Version":"2012-10-17",
    "Id": "PutObjectPolicy",
    "Statement": [
        {
"Sid": "RequireSSECObjectUploads",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
            "Null": {
              "s3:x-amz-server-side-encryption-customer-algorithm": "true"
                }
```

```
            }
        }
    ]
}
```

Important

If you use a bucket policy to require SSE-C on `s3:PutObject`, you must include the `x-amz-server-side-encryption-customer-algorithm` header in all multipart upload requests (CreateMultipartUpload, UploadPart, and CompleteMultipartUpload).

Presigned URLs and SSE-C

You can generate a presigned URL that can be used for operations such as uploading a new object, retrieving an existing object, or retrieving object metadata. Presigned URLs support SSE-C as follows:

- When creating a presigned URL, you must specify the algorithm by using the `x-amz-server-side-encryption-customer-algorithm` header in the signature calculation.
- When using the presigned URL to upload a new object, retrieve an existing object, or retrieve only object metadata, you must provide all the encryption headers in your client application's request.

Note

For non-SSE-C objects, you can generate a presigned URL and directly paste that URL into a browser to access the data.
However, you cannot do this for SSE-C objects, because in addition to the presigned URL, you also must include HTTP headers that are specific to SSE-C objects. Therefore, you can use presigned URLs for SSE-C objects only programmatically.

For more information about presigned URLs, see Download and upload objects with presigned URLs.

Making requests with SSE-C

At the time of object creation with the REST API, you can specify server-side encryption with customer-provided keys (SSE-C). When you use SSE-C, you must provide encryption key information using the S3 API headers required for requests to copy source objects encrypted with SSE-C. You can use AWS SDK wrapper libraries to add these headers to your request. If you need to, you can make the Amazon S3 REST API calls directly in your application.

> **Important**
>
> SSE-C is disabled by default for all new buckets. Before uploading objects with SSE-C, you must enable it by updating your bucket's default encryption configuration. For more information, see Blocking or unblocking SSE-C for a general purpose bucket.

> **Note**
>
> You cannot use the Amazon S3 console to upload an object and request SSE-C. You also cannot use the console to update (for example, change the storage class or add metadata) an existing object stored using SSE-C. For more information, see S3 API headers required for SSE-C object encryption and decryption requests.

Using the REST API

Amazon S3 REST APIs that support SSE-C

The following Amazon S3 APIs support server-side encryption with customer-provided encryption keys (SSE-C).

- **GET operation** – When retrieving objects using the GET API (see GET Object), you can specify the request headers.
- **HEAD operation** – To retrieve object metadata using the HEAD API (see HEAD Object), you can specify these request headers.
- **PUT operation** – When uploading data using the PUT Object API (see PUT Object), you can specify these request headers.
- **Multipart Upload** – When uploading large objects using the multipart upload API, you can specify these headers. You specify these headers in the initiate request (see Initiate Multipart

Upload) and each subsequent part upload request (see Upload Part or UploadPartCopy). For each part upload request, the encryption information must be the same as what you provided in the initiate multipart upload request.

- **POST operation** – When using a POST operation to upload an object (see POST Object), instead of the request headers, you provide the same information in the form fields.
- **Copy operation** – When you copy an object (see CopyObject), you have both a source object and a target object:
  - If you want to specify the target object's encryption type, you must provide the `x-amz-server-side-encryption` request header.
  - If you want the target object encrypted using SSE-C, you must provide encryption information using the S3 API S3 API headers required for SSE-C object encryption and decryption requests.
  - If the source object is encrypted using SSE-C, you must provide encryption key information using the S3 API headers S3 API headers required for requests to copy source objects encrypted with SSE-C.

Using the AWS SDKs to specify SSE-C for PUT, GET, Head, and Copy operations

The following examples show how to request server-side encryption with customer-provided keys (SSE-C) for objects. The examples perform the following operations. Each operation shows how to specify SSE-C-related headers in the request:

- **Put object** – Uploads an object and requests server-side encryption using a customer-provided encryption key.
- **Get object** – Downloads the object uploaded in the previous step. In the request, you provide the same encryption information you provided when you uploaded the object. Amazon S3 needs this information to decrypt the object so that it can return it to you.
- **Get object metadata** – Retrieves the object's metadata. You provide the same encryption information used when the object was created.
- **Copy object** – Makes a copy of the previously-uploaded object. Because the source object is stored using SSE-C, you must provide its encryption information in your copy request. By default, Amazon S3 encrypts the copy of the object only if you explicitly request it. This example directs Amazon S3 to store an encrypted copy of the object.

Java

> **Note**
>
> This example shows how to upload an object in a single operation. When using the Multipart Upload API to upload large objects, you provide encryption information in the same way shown in this example. For examples of multipart uploads that use the AWS SDK for Java, see Uploading an object using multipart upload.

To add the required encryption information, you include an `SSECustomerKey` in your request. For more information about the `SSECustomerKey` class, see the REST API section.

For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

        while ((line = reader.readLine()) != null) {
            System.out.println(line);
        }
        System.out.println();
    }
}
```

.NET

> **Note**
>
> For examples of uploading large objects using the multipart upload API, see Uploading an object using multipart upload and Using the AWS SDKs (low-level API).

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

Example

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.IO;
using System.Security.Cryptography;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SSEClientEncryptionKeyObjectOperationsTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** key name for new object created ***";
        private const string copyTargetKeyName = "*** key name for object copy ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
```

```
        {
            client = new AmazonS3Client(bucketRegion);
            ObjectOpsUsingClientEncryptionKeyAsync().Wait();
        }
        private static async Task ObjectOpsUsingClientEncryptionKeyAsync()
        {
            try
            {
                // Create an encryption key.
                Aes aesEncryption = Aes.Create();
                aesEncryption.KeySize = 256;
                aesEncryption.GenerateKey();
                string base64Key = Convert.ToBase64String(aesEncryption.Key);

                // 1. Upload the object.
                PutObjectRequest putObjectRequest = await
UploadObjectAsync(base64Key);
                // 2. Download the object and verify that its contents matches what
you uploaded.
                await DownloadObjectAsync(base64Key, putObjectRequest);
                // 3. Get object metadata and verify that the object uses AES-256
encryption.
                await GetObjectMetadataAsync(base64Key);
                // 4. Copy both the source and target objects using server-side
encryption with
                //    a customer-provided encryption key.
                await CopyObjectAsync(aesEncryption, base64Key);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered ***. Message:'{0}' when writing
an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
        }

 ServerSideEncryptionCustomerMethod.AES256,
                ServerSideEncryptionCustomerProvidedKey = copyBase64Key
            };
            await client.CopyObjectAsync(copyRequest);
        }
    }
}
```

Using the AWS SDKs to specify SSE-C for multipart uploads

The example in the preceding section shows how to request server-side encryption with customer-provided key (SSE-C) in the PUT, GET, Head, and Copy operations. This section describes other Amazon S3 APIs that support SSE-C.

Java

To upload large objects, you can use multipart upload APIs. For more information, see Uploading and copying objects using multipart upload in Amazon S3. You can use either high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using the high-level `TransferManager` API, you provide the encryption-specific headers in the `PutObjectRequest`. For more information, see Uploading an object using multipart upload.
- When using the low-level API, you provide encryption-related information in the `InitiateMultipartUploadRequest`, followed by identical encryption information in each `UploadPartRequest`. You do not need to provide any encryption-specific headers in your `CompleteMultipartUploadRequest`. For examples, see Using the AWS SDKs (low-level API).

The following example uses `TransferManager` to create objects and shows how to provide SSE-C related information. The example does the following:

- Creates an object using the `TransferManager.upload()` method. In the `PutObjectRequest` instance, you provide encryption key information in the request. Amazon S3 encrypts the object using the customer-provided key.

- Makes a copy of the object by calling the `TransferManager.copy()` method. The example directs Amazon S3 to encrypt the object copy using a new `SSECustomerKey`. Because the source object is encrypted using SSE-C, the `CopyObjectRequest` also provides the encryption key of the source object so that Amazon S3 can decrypt the object before copying it.

Example

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.CopyObjectRequest;
import com.amazonaws.services.s3.model.PutObjectRequest;
import com.amazonaws.services.s3.model.SSECustomerKey;
import com.amazonaws.services.s3.transfer.Copy;
import com.amazonaws.services.s3.transfer.TransferManager;
import com.amazonaws.services.s3.transfer.TransferManagerBuilder;
import com.amazonaws.services.s3.transfer.Upload;

import javax.crypto.KeyGenerator;
import java.io.File;
import java.security.SecureRandom;

public class ServerSideEncryptionCopyObjectUsingHLwithSSEC {

    public static void main(String[] args) throws Exception {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String fileToUpload = "*** File path ***";
        String keyName = "*** New object key name ***";
        String targetKeyName = "*** Key name for object copy ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withRegion(clientRegion)
                    .withCredentials(new ProfileCredentialsProvider())
                    .build();
            TransferManager tm = TransferManagerBuilder.standard()
```

```
                    .withS3Client(s3Client)
                    .build();

            // Create an object from a file.
            PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName,
keyName, new File(fileToUpload));

            // Create an encryption key.
            KeyGenerator keyGenerator = KeyGenerator.getInstance("AES");
            keyGenerator.init(256, new SecureRandom());
            SSECustomerKey sseCustomerEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());

            // Upload the object. TransferManager uploads asynchronously, so this
call
            // returns immediately.
            putObjectRequest.setSSECustomerKey(sseCustomerEncryptionKey);
            Upload upload = tm.upload(putObjectRequest);

            // Optionally, wait for the upload to finish before continuing.
            upload.waitForCompletion();
            System.out.println("Object created.");

            // Copy the object and store the copy using SSE-C with a new key.
            CopyObjectRequest copyObjectRequest = new CopyObjectRequest(bucketName,
keyName, bucketName, targetKeyName);
            SSECustomerKey sseTargetObjectEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());
            copyObjectRequest.setSourceSSECustomerKey(sseCustomerEncryptionKey);

copyObjectRequest.setDestinationSSECustomerKey(sseTargetObjectEncryptionKey);

            // Copy the object. TransferManager copies asynchronously, so this call
returns
            // immediately.
            Copy copy = tm.copy(copyObjectRequest);

            // Optionally, wait for the upload to finish before continuing.
            copy.waitForCompletion();
            System.out.println("Copy complete.");
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
```

```
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

.NET

To upload large objects, you can use multipart upload API (see Uploading and copying objects using multipart upload in Amazon S3). AWS SDK for .NET provides both high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using high-level `Transfer-Utility` API, you provide the encryption-specific headers in the `TransferUtilityUploadRequest` as shown. For code examples, see Uploading an object using multipart upload.

  ```
  TransferUtilityUploadRequest request = new TransferUtilityUploadRequest()
  {
      FilePath = filePath,
      BucketName = existingBucketName,
      Key = keyName,
      // Provide encryption information.
      ServerSideEncryptionCustomerMethod =
   ServerSideEncryptionCustomerMethod.AES256,
      ServerSideEncryptionCustomerProvidedKey = base64Key,
  };
  ```

- When using the low-level API, you provide encryption-related information in the initiate multipart upload request, followed by identical encryption information in the subsequent upload part requests. You do not need to provide any encryption-specific headers in your complete multipart upload request. For examples, see Using the AWS SDKs (low-level API).

  The following is a low-level multipart upload example that makes a copy of an existing large object. In the example, the object to be copied is stored in Amazon S3 using SSE-C, and you want to save the target object also using SSE-C. In the example, you do the following:

  - Initiate a multipart upload request by providing an encryption key and related information.
  - Provide source and target object encryption keys and related information in the `CopyPartRequest`.

- Obtain the size of the source object to be copied by retrieving the object metadata.
- Upload the objects in 5 MB parts.

Example

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.IO;
using System.Security.Cryptography;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SSECLowLevelMPUcopyObjectTest
    {
        private const string existingBucketName = "*** bucket name ***";
        private const string sourceKeyName      = "*** source object key name
 ***";
        private const string targetKeyName      = "*** key name for the target
 object ***";
        private const string filePath           = @"*** file path ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =

Blocking or unblocking SSE-C for a general purpose bucket

Starting April 2026, Amazon S3 automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. Amazon S3 also disabled SSE-C for existing buckets in accounts with no SSE-C encrypted objects. This means that by default, requests to upload objects using SSE-C are rejected with an HTTP 403 `AccessDenied` error.

SSE-C requires you to provide the encryption key with every request to read or write encrypted objects, making it difficult to share access with other users, roles, or AWS services that operate on your data. Most workloads use server-side encryption with Amazon S3 managed keys (SSE-S3) or AWS KMS keys (SSE-KMS) instead.

If your workload requires SSE-C, you can explicitly enable it by updating the default encryption configuration for your bucket. Conversely, if you have existing buckets where SSE-C is still allowed, you can block it to prevent new SSE-C uploads.

When SSE-C is blocked for a bucket, any `PutObject`, `CopyObject`, `PostObject`, Multipart Upload, or replication request that specifies SSE-C encryption will be rejected with an HTTP 403 `AccessDenied` error. Existing SSE-C encrypted objects in the bucket are unaffected, you can still read them with `GetObject` or `HeadObject` by providing the required SSE-C headers.

This setting is a parameter on the `PutBucketEncryption` API and can also be updated using the S3 console, AWS CLI, or AWS SDKs. You must have the `s3:PutEncryptionConfiguration` permission.

> **Important**
>
> Amazon Simple Storage Service now applies a new default bucket security setting that automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. In April 2026, Amazon S3 deployed an update so all new general purpose buckets have SSE-C encryption disabled for all new write requests. For existing buckets in AWS accounts with no SSE-C encrypted objects, Amazon S3 also disabled SSE-C for all new write requests. With this change, applications that need SSE-C encryption must deliberately enable SSE-C by using the PutBucketEncryption API operation after creating a new bucket. For more information about this change, see Default SSE-C setting for new buckets FAQ.

Permissions

Use the `PutBucketEncryption` API or the S3 Console, AWS SDKs, or AWS CLI to block or unblock encryption types for a general purpose bucket. You must have the following permission:

- `s3:PutEncryptionConfiguration`

Use the `GetBucketEncryption` API or the S3 Console, AWS SDKs, or AWS CLI to view blocked encryption types for a general purpose bucket. You must have the following permission:

- `s3:GetEncryptionConfiguration`

Considerations before blocking SSE-C encryption

After you block SSE-C for any bucket, the following encryption behavior applies:

- There is no change to the encryption of the objects that existed in the bucket before you blocked SSE-C encryption.
- After you block SSE-C encryption, you can continue to make GetObject and HeadObject requests on pre-existing objects encrypted with SSE-C as long as you provide the required SSE-C headers on the requests.

- When SSE-C is blocked for a bucket, any `PutObject`, `CopyObject`, `PostObject`, or Multipart Upload requests that specify SSE-C encryption will be rejected with an HTTP 403 `AccessDenied` error.
- If a destination bucket for replication has SSE-C blocked and the source objects being replicated are encrypted with SSE-C, the replication will fail with an HTTP 403 `AccessDenied` error.

If you want to review if you're using SSE-C encryption in any of your buckets before blocking this encryption type, you can use tools such as AWS CloudTrail to monitor access to your data. This blog post shows you how to audit encryption methods for object uploads in real time. You can also reference this re:Post article to guide you through the querying S3 Inventory reports to see if you have any SSE-C encrypted objects.

Steps

You can block or unblock server-side encryption with customer-provided keys (SSE-C) for a general purpose bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To block or unblock SSE-C encryption for a bucket using the Amazon S3 console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **general purpose buckets**.
3. Select the bucket that you would like to block SSE-C encryption for.
4. Select the **Properties** tab for the bucket.
5. Navigate to the **Default Encryption** properties panel for the bucket and select **Edit**.
6. In the **Blocked encryption types** section, check the box next to **Server-side encryption with customer-provided keys (SSE-C)** to block SSE-C encryption or uncheck this box to allow SSE-C.
7. Select **Save Changes**.

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to block or unblock SSE-C encryption for a general purpose bucket by using the AWS CLI. To use the command replace the *user input placeholders* with your own information.

Request to block SSE-C encryption for a general purpose bucket:

```
aws s3api put-bucket-encryption \
  --bucket amzn-s3-demo-bucket \
  --server-side-encryption-configuration '{
    "Rules": [{
      "BlockedEncryptionTypes": {
        "EncryptionType": ["SSE-C"]
      }
    }]
  }'
```

Request to enable the use of SSE-C encryption on a general purpose bucket:

```
aws s3api put-bucket-encryption \
  --bucket amzn-s3-demo-bucket \
  --server-side-encryption-configuration '{
    "Rules": [{
      "BlockedEncryptionTypes": {
        "EncryptionType": ["NONE"]
      }
    }]
  }'
```

Using the AWS SDKs

SDK for Java 2.x

The following examples show you how to block or unblock SSE-C encryption writes to your general purpose buckets by using the AWS SDKs

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and blocking SSE-C

```
S3Client s3Client = ...;
ServerSideEncryptionByDefault defaultSse = ServerSideEncryptionByDefault
        .builder()
```

```
        .sseAlgorithm(ServerSideEncryption.AES256)
        .build();
BlockedEncryptionTypes blockedEncryptionTypes = BlockedEncryptionTypes
        .builder()
        .encryptionType(EncryptionType.SSE_C)
        .build();
ServerSideEncryptionRule rule = ServerSideEncryptionRule.builder()
        .applyServerSideEncryptionByDefault(defaultSse)
        .blockedEncryptionTypes(blockedEncryptionTypes)
        .build();
s3Client.putBucketEncryption(be -> be
        .bucket(bucketName)
        .serverSideEncryptionConfiguration(c -> c.rules(rule)));
```

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and unblocking SSE-C

```
S3Client s3Client = ...;
ServerSideEncryptionByDefault defaultSse = ServerSideEncryptionByDefault
        .builder()
        .sseAlgorithm(ServerSideEncryption.AES256)
        .build();
BlockedEncryptionTypes blockedEncryptionTypes = BlockedEncryptionTypes
        .builder()
        .encryptionType(EncryptionType.NONE)
        .build();
ServerSideEncryptionRule rule = ServerSideEncryptionRule.builder()
        .applyServerSideEncryptionByDefault(defaultSse)
        .blockedEncryptionTypes(blockedEncryptionTypes)
        .build();
s3Client.putBucketEncryption(be -> be
        .bucket(bucketName)
        .serverSideEncryptionConfiguration(c -> c.rules(rule)));
```

SDK for Python (Boto3)

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and blocking SSE-C

```
s3 = boto3.client("s3")
s3.put_bucket_encryption(
    Bucket="amzn-s3-demo-bucket",
```

```
    ServerSideEncryptionConfiguration={
        "Rules":[{
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "AES256"
            },
            "BlockedEncryptionTypes": {
                "EncryptionType": ["SSE-C"]
            }
        }]
    }
)
```

Example - PutBucketEncryption request setting the default encryption configuration to SSE-S3 and unblocking SSE-C

```
s3 = boto3.client("s3")
s3.put_bucket_encryption(
    Bucket="amzn-s3-demo-bucket",
    ServerSideEncryptionConfiguration={
        "Rules":[{
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "AES256"
            },
            "BlockedEncryptionTypes": {
                "EncryptionType": ["NONE"]
            }
        }]
    }
)
```

Using the REST API

For information about the Amazon S3 REST API support for blocking or unblocking SSE-C encryption for a general purpose bucket, see the following section in the Amazon Simple Storage Service API Reference:

- BlockedEncryptionTypes data type used in the ServerSideEncryptionRule data type of the PutBucketEncryption and GetBucketEncryption API operations.

Default SSE-C setting for new buckets FAQ

> **Important**
>
> Amazon Simple Storage Service now applies a new default bucket security setting that automatically disables server-side encryption with customer-provided keys (SSE-C) for all new general purpose buckets. In April 2026, Amazon S3 deployed an update so all new general purpose buckets have SSE-C encryption disabled for all new write requests. For existing buckets in AWS accounts with no SSE-C encrypted objects, Amazon S3 also disabled SSE-C for all new write requests. With this change, applications that need SSE-C encryption must deliberately enable SSE-C by using the PutBucketEncryption API operation after creating a new bucket.

The following sections answer questions about this update.

1. Does the new SSE-C setting take effect for all newly created buckets?

Yes. This deployment completed in 37 AWS Regions, including the AWS China and AWS GovCloud (US) Regions, in April 2026.

> **Note**
>
> All newly created buckets in all AWS Regions except Middle East (Bahrain) and Middle East (UAE) will have SSE-C disabled by default.

2. Did Amazon S3 update my existing bucket configurations?

If your AWS account did not have any SSE-C encrypted objects, then AWS disabled SSE-C encryption on all of your existing buckets. If any bucket in your AWS account had SSE-C encrypted objects, then AWS did not change the bucket configurations on any of your buckets in that account. The new default setting applies to all new general purpose buckets.

3. Can I disable SSE-C encryption for my buckets?

Yes. You can disable SSE-C encryption for any bucket by calling the PutBucketEncryption API operation and specifying the new `BlockedEncryptionTypes` header.

4. Can I use SSE-C to encrypt data in my new buckets?

Yes. Most modern use cases in Amazon S3 no longer use SSE-C because it lacks the flexibility of server-side encryption is with Amazon S3 managed keys (SSE-S3) or server-side encryption with AWS KMS keys (SSE-KMS). If you need to use SSE-C encryption in a new bucket, you can create the new bucket and then enable the use of SSE-C encryption in a separate `PutBucketEncryption` request.

Example

```
aws s3api create-bucket \
bucket amzn-s3-demo-bucket \
region us-east-1 \

aws s3api put-bucket-encryption \
-- bucket amzn-s3-demo-bucket \
-- server-side-encryption-configuration \
'{ \Rules\: [{
   {
   \ApplyServerSideEncryptionByDefault\: {
     \SSEAlgorithm\: \AES256\,
    },
   \BlockedEncryptionTypes\: [
     \EncryptionType\:\NONE\]
   }
   }]
}'
```

Note

You must have the `s3:PutEncryptionConfiguration`permission to call the `PutBucketEncryption` API.

5. How does blocking SSE-C affect requests to my bucket?

When SSE-C is blocked for a bucket, any `PutObject`, `CopyObject`, `PostObject`, or Multipart Upload or replication requests that specify SSE-C encryption will be rejected with an HTTP 403 `AccessDenied` error.

Protecting data by using client-side encryption

Client-side encryption is the act of encrypting your data locally to help ensure its security in transit and at rest. To encrypt your objects before you send them to Amazon S3, use the Amazon S3 Encryption Client. When your objects are encrypted in this manner, your objects aren't exposed to any third party, including AWS. Amazon S3 receives your objects already encrypted; Amazon S3 does not play a role in encrypting or decrypting your objects. You can use both the Amazon S3 Encryption Client and server-side encryption to encrypt your data. When you send encrypted objects to Amazon S3, Amazon S3 doesn't recognize the objects as being encrypted, it only detects typical objects.

The Amazon S3 Encryption Client works as an intermediary between you and Amazon S3. After you instantiate the Amazon S3 Encryption Client, your objects are automatically encrypted and decrypted as part of your Amazon S3 `PutObject` and `GetObject` requests. Your objects are all encrypted with a unique data key. The Amazon S3 Encryption Client does not use or interact with bucket keys, even if you specify a KMS key as your wrapping key.

The *Amazon S3 Encryption Client Developer Guide* focuses on versions 3.0 and later of the Amazon S3 Encryption Client. For more information, see What is the Amazon S3 Encryption Client? in the *Amazon S3 Encryption Client Developer Guide*.

For more information about previous versions of the Amazon S3 Encryption client, see the AWS SDK Developer Guide for your programming language.

- AWS SDK for Java
- AWS SDK for .NET
- AWS SDK for Go
- AWS SDK for PHP
- AWS SDK for Ruby
- AWS SDK for C++

Protecting data in transit with encryption

Amazon S3 supports both HTTP and HTTPS protocols for data transmission. HTTP transmits data in plain text, while HTTPS adds a security layer by encrypting data using Transport Layer Security (TLS). TLS protects against eavesdropping, data tampering, and man-in-the-middle attacks. While

HTTP traffic is accepted, most implementations use encryption in transit with HTTPS and TLS to protect data as it travels between clients and Amazon S3.

TLS 1.2 and TLS 1.3 Support

Amazon S3 supports TLS 1.2 and TLS 1.3 for HTTPS connections across all API endpoints for all AWS Regions. S3 automatically negotiates the strongest TLS protection supported by your client software, and the S3 endpoint you are accessing. Current AWS tools (2014 or later) including the AWS SDKs and AWS CLI automatically default to TLS 1.3 with no action required on your part. You can override this automatic negotiation through client configuration settings to specify a particular TLS version if backward compatibility to TLS 1.2 is needed. When using TLS 1.3, you can optionally configure hybrid post quantum key exchange (ML-KEM) to make quantum-resistant requests to Amazon S3. For more information, see the section called “Configure PQ-TLS client”.

> **Note**
>
> TLS 1.3 is supported in all S3 endpoints, except for AWS PrivateLink for Amazon S3 and Multi-Region Access Points.

Monitoring TLS usage

You can use either Amazon S3 server access logs or AWS CloudTrail to monitor requests to Amazon S3 buckets. Both logging options record the TLS version and cipher suite used in each request.

- **Amazon S3 server access logs** – Server access logging provides detailed records for the requests that are made to a bucket. For example, access log information can be useful in security and access audits. For more information, see Amazon S3 server access log format.
- **AWS CloudTrail** – AWS CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. For more information, see Amazon S3 CloudTrail events.

Enforcing encryption in transit

It’s a security best practice to enforce encryption of data in transit to Amazon S3. You can enforce HTTPS-only communication or the use of specific TLS version through various policy mechanisms. These include IAM resource-based policies for S3 buckets (bucket policies), Service Control Policies (SCPs), Resource Control Policies (RCPs), and VPC endpoint policies.

Bucket policy examples for enforcing encryption in transit

You can use the S3 condition key `s3:TlsVersion` to restrict access to Amazon S3 buckets based on the TLS version that's used by the client. For more information, see Example 6: Requiring a minimum TLS version.

Example bucket policy enforcing TLS 1.3 using the `S3:TlsVersion` condition key

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyInsecureConnections",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket1",
        "arn:aws:s3:::amzn-s3-demo-bucket1/*"
      ],
      "Condition": {
        "NumericLessThan": {
          "s3:TlsVersion": "1.3"
        }
      }
    }
  ]
}
```

You can use the `aws:SecureTransport` global condition key in your S3 bucket policy to check whether the request was sent through HTTPS (TLS). Unlike the previous example, this condition does not check for a specific TLS version. For more information, see Restrict access to only HTTPS requests.

Example bucket policy enforcing HTTPS using the `aws:SecureTransport` global condition key

```
{
    "Version":"2012-10-17",
    "Statement": [
     {
        "Sid": "RestrictToTLSRequestsOnly",
        "Action": "s3:*",
```

```
        "Effect": "Deny",
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket1",
            "arn:aws:s3:::amzn-s3-demo-bucket1/*"
        ],
        "Condition": {
            "Bool": {
                "aws:SecureTransport": "false"
            }
        },
        "Principal": "*"
    }
  ]
}
```

Example policy based on both keys and more examples

You can use both types of condition keys in the previous examples in one policy. For more information and additional enforcement approaches, see the AWS Storage Blog article Enforcing encryption in transit with TLS1.2 or higher with Amazon S3.

Using hybrid post-quantum TLS with Amazon S3

Amazon S3 supports a hybrid post-quantum key exchange option for the TLS network encryption protocol. You can use this TLS option when you make requests to Amazon S3 endpoints utilizing TLS 1.3. The classic cipher suites that S3 supports for TLS sessions make brute force attacks on the key exchange mechanisms infeasible with current technology. However, if a cryptographically relevant quantum computer becomes practical in the future, the classic cipher suites used in TLS key exchange mechanisms will be susceptible to these attacks. At present, the industry is aligned on hybrid post-quantum key exchange that combines classic and post-quantum elements to ensure that your TLS connection is at least as strong as it would be with classic cipher suites. Amazon S3 supports hybrid PQ-TLS, in compliance with the industry-standard IANA specification, today.

If you're developing applications that rely on the long-term confidentiality of data passed over a TLS connection, you should consider a plan to migrate to post-quantum cryptography before large-scale quantum computers become available for use. As part of the shared responsibility model, S3 enables quantum-safe cryptography on our service endpoints. As browsers and applications enable PQ-TLS on their side, S3 will choose the strongest possible configuration to secure data in transit.

Supported endpoint types and AWS Regions

Post-quantum TLS for Amazon S3 is available in all AWS Regions. For a list of S3 endpoints for each AWS Region, see Amazon Simple Storage Service endpoints and quotas in the *Amazon Web Services General Reference*.

> **Note**
>
> Hybrid post-quantum TLS is supported for all S3 endpoints except for AWS PrivateLink for Amazon S3, Multi-Region Access Points, and S3 Vectors.

Using hybrid post-quantum TLS with Amazon S3

You must configure the client that makes requests to Amazon S3 to support hybrid post-quantum TLS. When setting up your HTTP client test environment or production environments, be aware of the following information:

Encryption in Transit

Hybrid post-quantum TLS is only used for encryption in transit. This protects your data while it is traveling from your client to the S3 endpoint. This new support combined with Amazon S3's server-side encryption by default utilizing AES-256 algorithms offers customers quantum-resistant encryption both in-transit and at-rest. For more information about server-side encryption in Amazon S3, see Protecting data with server-side encryption.

Supported Clients

The use of hybrid post-quantum TLS requires using a client that supports this functionality. AWS SDKs and tools have cryptographic capabilities and configuration that differ across languages and runtimes. To learn more about post-quantum cryptography for specific tools, see Enabling hybrid post-quantum TLS.

> **Note**
>
> PQ-TLS key exchange details for requests to Amazon S3 are not available in AWS CloudTrail events or S3 server access logs.

Learn more about post-quantum TLS

For more information about using hybrid post-quantum TLS, see the following resources.

- To learn about post-quantum cryptography at AWS, including links to blog posts and research papers, see Post-Quantum Cryptography for AWS.
- For information about s2n-tls, see Introducing s2n-tls, a New Open Source TLS Implementation and Using s2n-tls.
- For information about the AWS Common Runtime HTTP Client, see Configuring the AWS CRT-based HTTP client in the *AWS SDK for Java 2.x Developer Guide*.
- For information about the post-quantum cryptography project at the National Institute for Standards and Technology (NIST), see Post-Quantum Cryptography.
- For information about NIST post-quantum cryptography standardization, see NIST's Post-Quantum Cryptography Standardization.

Configuring hybrid post-quantum TLS for your client

To use PQ-TLS with Amazon S3, you need to configure your client to support post-quantum key exchange algorithms. Also ensure that your client supports the hybrid approach, which combines traditional elliptic curve cryptography with post-quantum algorithms like ML-KEM (Module-Lattice-Based Key Encapsulation Mechanism).

The specific configuration depends on your client library and programming language. For more information, see Enabling hybrid post-quantum TLS.

Client configuration example: AWS SDK for Java 2

In this procedure, add a Maven dependency for the AWS Common Runtime HTTP Client. Next, configure an HTTP client that prefers post-quantum TLS. Then, create an Amazon S3 client that uses the HTTP client.

> **Note**
>
> The AWS Common Runtime HTTP Client, which has been available as a preview, became generally available in February 2023. In that release, the `tlsCipherPreference` class and the `tlsCipherPreference()` method parameter are replaced by the `postQuantumTlsEnabled()` method parameter. If you were using this example during the preview, you need to update your code.

1. Add the AWS Common Runtime client to your Maven dependencies. We recommend using the latest available version.

For example, this statement adds version `2.30.22` of the AWS Common Runtime client to your Maven dependencies.

```
<dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>aws-crt-client</artifactId>
    <version>2.30.22</version>
</dependency>
```

2. To enable the hybrid post-quantum cipher suites, add the AWS SDK for Java 2.x to your project and initialize it. Then enable the hybrid post-quantum cipher suites on your HTTP client as shown in the following example.

   This code uses the `postQuantumTlsEnabled()` method parameter to configure an AWS common runtime HTTP client that prefers the recommended hybrid post-quantum cipher suite, ECDH with ML-KEM. Then it uses the configured HTTP client to build an instance of the Amazon S3 asynchronous client, `S3AsyncClient`. After this code completes, all Amazon S3 API requests on the `S3AsyncClient` instance use hybrid post-quantum TLS.

   > **Important**
   >
   > As of v2.35.11, callers no longer need to set `.postQuantumTlsEnabled(true)` to enable hybrid post-quantum TLS for your client. All versions newer than v2.35.11 enable post-quantum TLS by default.

   ```
   // Configure HTTP client
   SdkAsyncHttpClient awsCrtHttpClient = AwsCrtAsyncHttpClient.builder()
              .postQuantumTlsEnabled(true)
              .build();

   // Create the Amazon S3 async client
   S3AsyncClient s3Async = S3AsyncClient.builder()
             .httpClient(awsCrtHttpClient)
             .build();
   ```

3. Test your Amazon S3 calls with hybrid post-quantum TLS.

When you call Amazon S3 API operations on the configured Amazon S3 client, your calls are transmitted to the Amazon S3 endpoint using hybrid post-quantum TLS. To test your configuration, call an Amazon S3 API, such as `ListBuckets`.

```
ListBucketsResponse reponse = s3Async.listBuckets();
```

Test your hybrid post-quantum TLS configuration

Consider running the following tests with hybrid cipher suites on your applications that call Amazon S3.

- Run load tests and benchmarks. The hybrid cipher suites perform differently than traditional key exchange algorithms. You might need to adjust your connection timeouts to allow for the longer handshake times. If you're running inside an AWS Lambda function, extend the execution timeout setting.
- Try connecting from different locations. Depending on the network path your request takes, you might discover that intermediate hosts, proxies, or firewalls with deep packet inspection (DPI) block the request. This might result from using the new cipher suites in the ClientHello part of the TLS handshake, or from the larger key exchange messages. If you have trouble resolving these issues, work with your security team or IT administrators to update the relevant configuration and unblock the new TLS cipher suites.

Internetwork traffic privacy

This topic describes how Amazon S3 secures connections from the service to other locations.

Traffic between service and on-premises clients and applications

The following connections can be combined with AWS PrivateLink to provide connectivity between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An Direct Connect connection. For more information, see What is Direct Connect?

Access to Amazon S3 through the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend utilizing TLS 1.3 with hybrid post-quantum

key exchange. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the AWS Security Token Service (STS) to generate temporary security credentials to sign requests.

Traffic between AWS resources in the same Region

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC routes requests to Amazon S3 and routes responses back to the VPC. For more information, see VPC Endpoints in the *VPC User Guide*. For example bucket policies that you can use to control S3 bucket access from VPC endpoints, see Controlling access from VPC endpoints with bucket policies.

AWS PrivateLink for Amazon S3

With AWS PrivateLink for Amazon S3, you can provision *interface VPC endpoints* (interface endpoints) in your virtual private cloud (VPC). These endpoints are directly accessible from applications that are on premises over VPN and Direct Connect, or in a different AWS Region over VPC peering.

Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests to Amazon S3 over interface endpoints stay on the Amazon network. You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (Site-to-Site VPN). For more information about how to connect your VPC with your on-premises network, see the Direct Connect User Guide and the AWS Site-to-Site VPN User Guide.

For general information about interface endpoints, see Interface VPC endpoints (AWS PrivateLink) in the *AWS PrivateLink Guide*.

Topics

- Types of VPC endpoints for Amazon S3
- Restrictions and limitations of AWS PrivateLink for Amazon S3
- Creating a VPC endpoint
- Accessing Amazon S3 interface endpoints
- IP Address types for VPC endpoints

- DNS record IP types for VPC endpoints
- Private DNS
- Accessing buckets, access points, and Amazon S3 Control API operations from S3 interface endpoints
- Updating an on-premises DNS configuration
- Creating a VPC endpoint policy for Amazon S3

Types of VPC endpoints for Amazon S3

You can use two types of VPC endpoints to access Amazon S3: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access Amazon S3 from your VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to Amazon S3 from within your VPC, on premises, or from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway. For more information, see What is VPC peering? and Transit Gateway vs VPC peering.

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the VPC, you can use both types of endpoints in the same VPC.

Gateway endpoints for Amazon S3	Interface endpoints for Amazon S3
In both cases, your network traffic remains on the AWS network.	
Use Amazon S3 public IP addresses	Use private IP addresses from your VPC to access Amazon S3
Use the same Amazon S3 DNS names	Require endpoint-specific Amazon S3 DNS names
Do not allow access from on premises	Allow access from on premises
Do not allow access from another AWS Region	Allow access from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway
Not billed	Billed

For more information, see Gateway endpoints and interface VPC endpoints in the *AWS PrivateLink Guide*.

Restrictions and limitations of AWS PrivateLink for Amazon S3

VPC limitations apply to AWS PrivateLink for Amazon S3. For more information, see Interface endpoint considerations and AWS PrivateLink quotas in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

Interface endpoints for Amazon S3 does not support the following:

- Website endpoints
- Legacy global endpoints
- S3 dash Region endpoints
- Using CopyObject or UploadPartCopy between buckets in different AWS Regions
- Transport Layer Security (TLS) 1.0
- Transport Layer Security (TLS) 1.1
- Transport Layer Security (TLS) 1.3
- Hybrid post-quantum Transport Layer Security (TLS)

Creating a VPC endpoint

To create a VPC interface endpoint, see Create a VPC endpoint in the *AWS PrivateLink Guide*. To create a VPC gateway endpoint, see Create a gateway endpoint in the *AWS PrivateLink Guide*.

FIPS endpoints for Amazon S3

To connect to Amazon S3 over AWS PrivateLink with FIPS 140-3 validated cryptographic modules, create an interface endpoint. Use the FIPS service name `com.amazonaws.region.s3-fips`. For example, use `com.amazonaws.us-east-1.s3-fips`. FIPS interface endpoints are available in all AWS Regions that offer FIPS endpoints for Amazon S3. These endpoints support access to buckets, access points, and Amazon S3 Control API operations. You can configure FIPS interface endpoints to use IPv4, IPv6, or dual-stack IP addressing.

Accessing Amazon S3 interface endpoints

When you create an interface endpoint, Amazon S3 generates two types of endpoint-specific, S3 DNS names: *Regional* and *zonal*.

- A *Regional* DNS name includes a unique VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for VPC endpoint ID *vpce-1a2b3c4d*, the DNS name generated might be similar to *vpce-1a2b3c4d-5e6f*`.s3.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, *vpce-1a2b3c4d-5e6f*`-us-east-1a.s3.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Endpoint-specific S3 DNS names can be resolved from the S3 public DNS domain.

If you create an interface endpoint that uses the FIPS service name `com.amazonaws.`*region*`.s3-fips`, Amazon S3 generates endpoint-specific DNS names. These names include the `s3-fips` service identifier. For example, *vpce-1a2b3c4d-5e6f*`.s3-fips.us-east-1.vpce.amazonaws.com`.

VPC endpoints for Amazon S3 support different types of IP addressing, including: IPv4, IPv6, and Dualstack. See IP Address types for VPC endpoints and DNS record IP types for VPC endpoints.

IP Address types for VPC endpoints

VPC endpoints for Amazon S3 support different types of IP addressing, including:

- **IPv4**

  VPC endpoints can be configured to use only IPv4 addresses for connectivity.

- **IPv6**

  VPC endpoints can be configured to use only IPv6 addresses for connectivity.

- **Dual-stack**

  VPC endpoints can be configured in dual-stack mode, supporting both IPv4 and IPv6 addresses simultaneously. This provides flexibility to access Amazon S3 over either IPv4 or IPv6 networks.

The IP address type you choose for your VPC endpoint will depend on the networking requirements of your applications and infrastructure. Considerations may include the IP addressing schemes used in your VPC, on-premises networks, and across the internet connectivity to Amazon S3. For more information, see IP address types for interface endpoints and gateway endpoints in the *Amazon Virtual Private Cloud* guide.

DNS record IP types for VPC endpoints

Depending on your IP address type, when you call a VPC endpoint, the AWS service can return A records, AAAA records, or both A and AAAA records. You can customize which record types your AWS service returns by modifying the DNS record IP type. The following table shows the supported DNS record IP types and the IP address types:

Supported IP address types	DNS record IP types
IPv4	IPv4
IPv6	IPv6
Dualstack	Dualstack, IPv4, IPv6, Service-defined

Configuring the service-defined DNS record IP type for Amazon S3

If you create a gateway endpoint for Amazon S3 and configure the DNS record IP type as service-defined and use the regional service endpoint,(such as `s3.us-east-2.amazonaws.com`), Amazon S3 returns A records to your clients. In contrast, if you create a gateway endpoint and are using a dual-stack service endpoint, (such as `s3.dualstack.us-east-2.amazonaws.com`) and select the DNS record IP type as `service-defined`, Amazon S3 returns both A and AAAA records to your clients.

Similarly, if you create an interface endpoint with Private DNS enabled and choose service-defined as the DNS record type, for the regional service endpoint, (such as, `s3.us-east-2.amazonaws.com`), Amazon S3 returns A records to your client. Whereas, for a dualstack service endpoint, (such as, `s3.dualstack.us-east-2.amazonaws.com`), Amazon S3 returns both A and AAAA records. For more information, see DNS record IP type for interface endpoints and gateway endpoints in the *VPC User Guide*.

The following table shows the supported DNS record IP types for gateway and interface endpoints:

IP address type	Supported DNS record IP types for S3 Gateway endpoints	Supported DNS record IP types for S3 Interface endpoints
IPv4	IPv4, service-defined*	IPv4
IPv6	IPv6, service-defined*	IPv6
Dualstack	IPv4, IPv6, Dualstack, service-defined*	Dualstack*, IPv4, IPv6, service-defined

* Represents the default DNS record IP type.

To enable IPv6 connectivity on an existing S3 gateway or interface endpoint, update the IP address type for the endpoint to **`Dualstack`**. When updated, Amazon S3 automatically updates the routing tables with IPv6 addresses for gateway endpoints. Then you can use the dualstack service endpoint, such as `s3.dualstack.us-east-2.amazonaws.com`, and Amazon S3 will return both `A` and `AAAA` records for dualstack S3 DNS queries. If you want to use IPV6 with the regional service endpoint, such as `s3.us-east-2.amazonaws.com`, modify the IP address type for the endpoint to **`Dualstack`**; and the DNS record IP type to **`Dualstack`**. Then Amazon S3 will return both `A` and `AAAA` records for the regional S3 DNS queries.

Considerations

- If your gateway endpoint has the default configuration of IP address type as `IPv4` and DNS record IP type as `service-defined`, then the dualstack service endpoint (such as `s3.dualstack.us-east-2.amazonaws.com`), traffic that uses `AAAA` records won't be routed through the gateway endpoint. Instead, this traffic will be dropped or routed over an IPv6-compatible path if one is present. For example, if your virtual private cloud (VPC) has an internet gateway, your IPv6 traffic will be routed over the internet gateway in your VPC in this scenario. If you want to ensure your traffic is always routed over a VPC endpoint, you can use an Amazon S3 bucket policy that restricts access to a specific bucket if a specified VPC endpoint is not used. For more information, see Restricting access to a specific VPC endpoint.
- If your interface endpoint has the default configuration of IP address type, which is IPv4, and DNS record IP type as IPv4, dualstack service endpoints, such as

ass3.dualstack.us-east-2.amazonaws.com, are not supported. Traffic that uses the A or AAAA records of the dualstack service endpoints won't be routed through the interface endpoint. Instead, this traffic will be dropped or routed over another compatible path if one is present.

- Creating or modifying a gateway endpoint with a DNS record IP type other than service-defined requires both the enableDnsSupport and enableDnsHostnames VPC attributes to be set to true.

Private DNS

Private DNS options for VPC interface endpoints simplify routing S3 traffic over VPC endpoints and help you take advantage of the lowest-cost network path available to your application. You can use private DNS options to route Regional S3 traffic without updating your S3 clients to use the endpoint-specific DNS names of your interface endpoints, or managing DNS infrastructure. With private DNS names enabled, Regional S3 DNS queries resolve to the private IP addresses of AWS PrivateLink for the following endpoints:

- Regional bucket endpoints (for example, s3.us-east-1.amazonaws.com, or s3-fips.us-east-1.amazonaws.com for FIPS)
- Control endpoints (for example, s3-control.us-east-1.amazonaws.com, or s3-control-fips.us-east-1.amazonaws.com for FIPS)
- Access point endpoints (for example, s3-accesspoint.us-east-1.amazonaws.com, or s3-accesspoint-fips.us-east-1.amazonaws.com for FIPS)

If you configure the interface endpoint with the **Dualstack** IP address type, the FIPS dual-stack endpoints also resolve to the private IP addresses of AWS PrivateLink. For example, s3-fips.dualstack.us-east-1.amazonaws.com resolves to a private IP address.

If you have a gateway endpoint in your VPC, you can automatically route in-VPC requests over your existing S3 gateway endpoint and on-premises requests over your interface endpoint. This approach allows you to optimize your networking costs by using gateway endpoints, which are not billed, for your in-VPC traffic. Your on-premises applications can use AWS PrivateLink with the help of the inbound Resolver endpoint. Amazon provides a DNS server, called the Route 53 Resolver, for your VPC. An inbound Resolver endpoint forwards DNS queries from the on-premises network to Route 53 Resolver.

Important

To take advantage of the lowest cost network path when using **Enable private DNS only for inbound endpoints**, a gateway endpoint must be present in your VPC. The presence of a gateway endpoint helps ensure that in-VPC traffic always routes over the AWS private network when the **Enable private DNS only for inbound endpoints** option is selected. You must maintain this gateway endpoint while you have the **Enable private DNS only for inbound endpoints** option selected. If you want to delete your gateway endpoint you must first clear **Enable private DNS only for inbound endpoints**.
If you want to update an existing interface endpoint to **Enable private DNS only for inbound endpoints**, first confirm that your VPC has an S3 gateway endpoint. For more information about gateway endpoints and managing private DNS names, see Gateway VPC endpoints and Manage DNS names respectively in the *AWS PrivateLink Guide*.
When enabling **Private DNS for inbound resolver only**, the `dnsRecordIpType` of the gateway endpoint must either match that of interface endpoint or be **service defined**.

The **Enable private DNS only for inbound endpoints** option is available only for services that support gateway endpoints.

For more information about creating a VPC endpoint that uses **Enable private DNS only for inbound endpoints**, see Create an interface endpoint in the *AWS PrivateLink Guide*.

Using the VPC console

In the console you have two options: **Enable DNS name** and **Enable private DNS only for inbound endpoints**. **Enable DNS name** is an option supported by AWS PrivateLink. By using the **Enable DNS name** option, you can use Amazon's private connectivity to Amazon S3, while making requests to the default public endpoint DNS names. When this option is enabled, customers can take advantage of the lowest cost network path available to their application.

When you enable private DNS names on an existing or new VPC interface endpoint for Amazon S3, the **Enable private DNS only for inbound endpoints** option is selected by default. If this option is selected, your applications use only interface endpoints for your on-premises traffic. This in-VPC traffic automatically uses the lower-cost gateway endpoints. Alternatively, you can clear **Enable private DNS only for inbound endpoints** to route all S3 requests over your interface endpoint.

Using the AWS CLI

If you don't specify a value for `PrivateDnsOnlyForInboundResolverEndpoint`, it will default to `true`. However, before your VPC applies your settings, it performs a check to make sure that you have a gateway endpoint present in the VPC. If a gateway endpoint is present in the VPC, the call succeeds. If not, you will see the following error message:

To set PrivateDnsOnlyForInboundResolverEndpoint to true, the VPC *vpce_id* must have a gateway endpoint for the service.

For a new VPC Interface endpoint

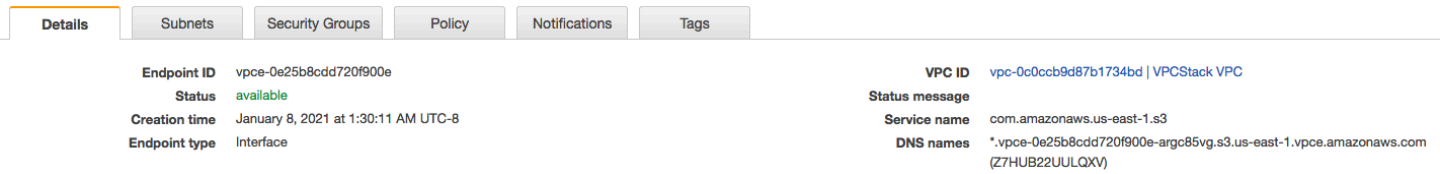
Use the `private-dns-enabled` and `dns-options` attributes to enable private DNS through the command line. The `PrivateDnsOnlyForInboundResolverEndpoint` option in the `dns-options` attribute must be set to `true`. Replace the *user input placeholders* with your own information.

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name s3-service-name \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface  \
--private-dns-enabled  \
--ip-address-type ip-address-type \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true \
--security-group-ids client-sg-id
```

For an existing VPC endpoint

If you want to use private DNS for an existing VPC endpoint, use the following example command and replace the *user input placeholders* with your own information.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=false
```



If you want to update an existing VPC endpoint to enable private DNS only for the Inbound Resolver, use the following example and replace the sample values with your own.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true
```

Accessing buckets, access points, and Amazon S3 Control API operations from S3 interface endpoints

You can use the AWS CLI or AWS SDKs to access buckets, S3 access points, and Amazon S3 Control API operations through S3 interface endpoints.

The following image shows the VPC console **Details** tab, where you can find the DNS name of a VPC endpoint. In this example, the *VPC endpoint ID (vpce-id)* is `vpce-0e25b8cdd720f900e` and the *DNS name* is `*.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com`.

When using the DNS name to access a resource, replace `*` with the appropriate value. The appropriate values to use in place of `*` are as follows:

- `bucket`
- `accesspoint`
- `control`

For example, to access a bucket, use a *DNS name* like this:

`bucket.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com`

For examples of how to use DNS names to access buckets, access points, and Amazon S3 Control API operations, see the following sections of AWS CLI examples and AWS SDK examples.

For more information about how to view your endpoint-specific DNS names, see Viewing endpoint service private DNS name configuration in the *VPC User Guide*.

AWS CLI examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Use an endpoint URL to list objects in your bucket

In the following example, replace the bucket name *my-bucket*, Region *us-east-1*, and the DNS name of the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
aws s3 ls s3://my-bucket/ --region us-east-1 --endpoint-url
 https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

Example: Use an endpoint URL to list objects from an access point

- **Method 1** – Using the Amazon Resource Name (ARN) of the access point with the access point endpoint

  Replace the ARN *us-east-1:123456789012:accesspoint/accesspointexamplename*, the Region *us-east-1*, and the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

  ```
  aws s3api list-objects-v2 --bucket arn:aws:s3:us-east-1:123456789012:accesspoint/
  accesspointexamplename --region us-east-1 --endpoint-url
   https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
  ```

  If you can't run the command successfully, update your AWS CLI to the latest version and try again. For more information on the update instructions, see Installing or updating the latest version of the AWS CLI in the *AWS Command Line Interface User Guide*.
- **Method 2** – Using the alias of the access point with the regional bucket endpoint

  In the following example, replace the access point alias *accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias*,

the Region *us-east-1*, and the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
aws s3api list-objects-v2 --
bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias
 --region us-east-1 --endpoint-url https://bucket.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com
```

- **Method 3** – Using the alias of the access point with the access point endpoint

  First, to construct an S3 endpoint with the bucket included as part of the hostname, set the addressing style to `virtual` for `aws s3api` to use. For more information about `AWS configure`, see Configuration and credential file settings in the *AWS Command Line Interface User Guide*.

  ```
  aws configure set default.s3.addressing_style virtual
  ```

  Then, in the following example, replace the access point alias *accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias*, the Region *us-east-1*, and the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information. For more information about access point alias, see Access point aliases.

  ```
  aws s3api list-objects-v2 --
  bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias --
  region us-east-1 --endpoint-url https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
  east-1.vpce.amazonaws.com
  ```

Example: Use an endpoint URL to list jobs with an S3 control API operation

In the following example, replace the Region *us-east-1*, the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com*, and the account ID *12345678* with your own information.

```
aws s3control --region us-east-1 --endpoint-url
 https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com list-jobs --
account-id 12345678
```

AWS SDK examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then configure your clients to use an endpoint URL for accessing a bucket, access point, or Amazon S3 Control API operations through S3 interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
s3_client = session.client(
service_name='s3',
region_name='us-east-1',
endpoint_url='https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'
)
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
ap_client = session.client(
service_name='s3',
region_name='us-east-1',
endpoint_url='https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com'
)
```

Example: Use an endpoint URL to access the Amazon S3 Control API

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
control_client = session.client(
service_name='s3control',
region_name='us-east-1',
endpoint_url='https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'
```

```
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
// bucket client
final AmazonS3 s3 = AmazonS3ClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
List<Bucket> buckets = s3.listBuckets();
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and ARN *us-east-1:123456789012:accesspoint/prod* with your own information.

```
// accesspoint client
final AmazonS3 s3accesspoint =
 AmazonS3ClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
ObjectListing objects = s3accesspoint.listObjects("arn:aws:s3:us-
east-1:123456789012:accesspoint/prod");
```

Example: Use an endpoint URL to access an Amazon S3 Control API operation

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
// control client
```

```
final AWSS3Control s3control =
 AWSS3ControlClient.builder().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://control.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
final ListJobsResult jobs = s3control.listJobs(new ListJobsRequest());
```

SDK for Java 2.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and the Region *Region.US_EAST_1* with your own information.

```
// bucket client
Region region = Region.US_EAST_1;
s3Client = S3Client.builder().region(region)

 .endpointOverride(URI.create("https://bucket.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com"))
                   .build()
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and the Region *Region.US_EAST_1* with your own information.

```
// accesspoint client
Region region = Region.US_EAST_1;
s3Client = S3Client.builder().region(region)

 .endpointOverride(URI.create("https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com"))
                   .build()
```

Example: Use an endpoint URL to access the Amazon S3 Control API

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and the Region *Region.US_EAST_1* with your own information.

```
// control client
Region region = Region.US_EAST_1;
s3ControlClient = S3ControlClient.builder().region(region)

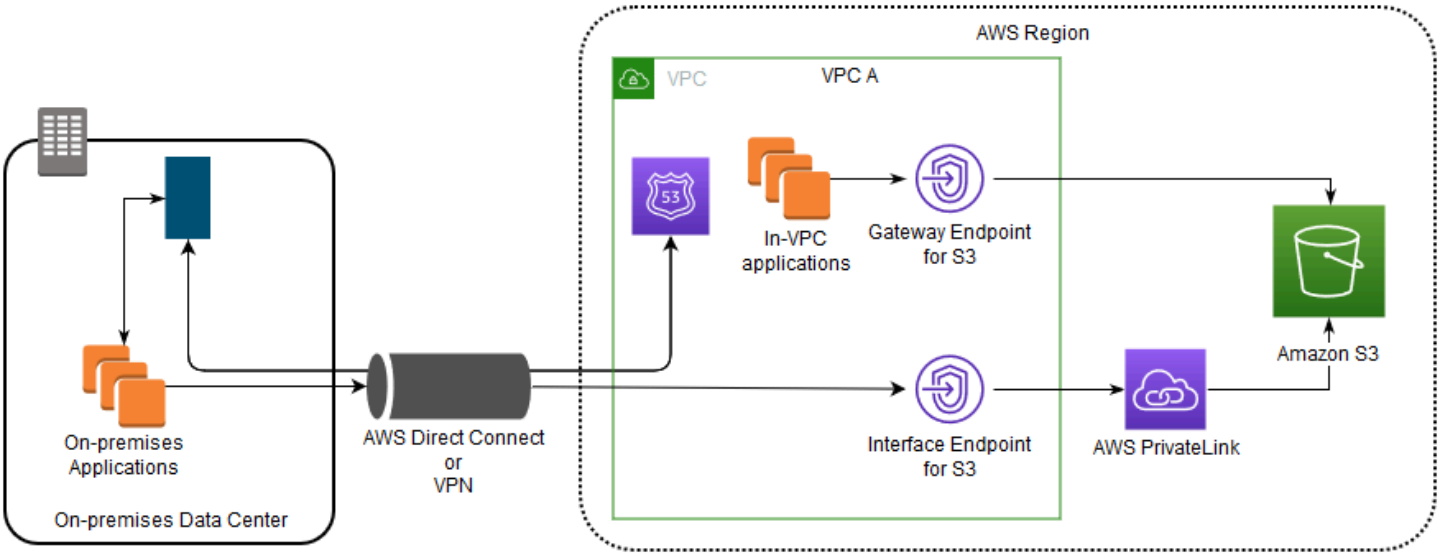
 .endpointOverride(URI.create("https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
                                  .build()
```

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for Amazon S3, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public Amazon S3 DNS domain.

Using interface endpoints to access Amazon S3 without a gateway endpoint or an internet gateway in the VPC

Interface endpoints in your VPC can route both in-VPC applications and on-premises applications to Amazon S3 over the Amazon network, as illustrated in the following diagram.



The diagram illustrates the following:

- Your on-premises network uses Direct Connect or Site-to-Site VPN to connect to VPC A.
- Your applications on-premises and in VPC A use endpoint-specific DNS names to access Amazon S3 through the S3 interface endpoint.
- On-premises applications send data to the interface endpoint in the VPC through Direct Connect (or Site-to-Site VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- In-VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.

Using gateway endpoints and interface endpoints together in the same VPC to access Amazon S3

You can create interface endpoints and retain the existing gateway endpoint in the same VPC, as the following diagram shows. By taking this approach, you allow in-VPC applications to continue accessing Amazon S3 through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access Amazon S3. To access Amazon S3 this way, you must update your on-premises applications to use endpoint-specific DNS names for Amazon S3.

The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the VPC through Direct Connect (or Site-to-Site VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.

- Using default Regional Amazon S3 names, in-VPC applications send data to the gateway endpoint that connects to Amazon S3 over the AWS network.

For more information about gateway endpoints, see Gateway VPC endpoints in the *VPC User Guide*.

Creating a VPC endpoint policy for Amazon S3

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon S3. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

You can also use Amazon S3 bucket policies to restrict access to specific buckets from a specific VPC endpoint by using the `aws:sourceVpce` condition in your bucket policy. The following examples show policies that restrict access to a bucket or to an endpoint.

Topics

- Example: Restricting access to a specific bucket from a VPC endpoint
- Example: Restricting access to buckets in a specific account from a VPC endpoint
- Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

Example: Restricting access to a specific bucket from a VPC endpoint

You can create an endpoint policy that restricts access to only specific Amazon S3 buckets. This type of policy is useful if you have other AWS services in your VPC that use buckets. The following bucket policy restricts access to only the *`amzn-s3-demo-bucket1`*. To use this endpoint policy, replace *`amzn-s3-demo-bucket1`* with the name of your bucket.

JSON

```
{
  "Version":"2012-10-17",
  "Id": "Policy1415115909151",
  "Statement": [
    { "Sid": "Access-to-specific-bucket-only",
```

```
      "Principal": "*",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket1",
                   "arn:aws:s3:::amzn-s3-demo-bucket1/*"]
    }
  ]
}
```

Example: Restricting access to buckets in a specific account from a VPC endpoint

You can create an endpoint policy that restricts access to only the S3 buckets in a specific AWS account. To prevent clients within your VPC from accessing buckets that you don't own, use the following statement in your endpoint policy. The following example statement creates a policy that restricts access to resources owned by a single AWS account ID, *111122223333*.

```
{
  "Statement": [
    {
      "Sid": "Access-to-bucket-in-specific-account-only",
      "Principal": "*",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Effect": "Deny",
      "Resource": "arn:aws:s3:::*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": "111122223333"
        }
      }
    }
  ]
}
```

Note

To specify the AWS account ID of the resource being accessed, you can use either the `aws:ResourceAccount` or the `s3:ResourceAccount` key in your IAM policy. However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources.

Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

The following Amazon S3 bucket policy allows access to a specific bucket, *amzn-s3-demo-bucket2*, from only the VPC endpoint *vpce-1a2b3c4d*. The policy denies all access to the bucket if the specified endpoint is not being used. The `aws:sourceVpce` condition specifies the endpoint and doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the endpoint ID. To use this bucket policy, replace *amzn-s3-demo-bucket2* and *vpce-1a2b3c4d* with your bucket name and endpoint.

Important

- When applying the following Amazon S3 bucket policy to restrict access to only certain VPC endpoints, you might block your access to the bucket without intending to do so. Bucket policies that are intended to specifically limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For information about how to fix this issue, see My bucket policy has the wrong VPC or VPC endpoint ID. How can I fix the policy so that I can access the bucket? in the *Support Knowledge Center*.
- Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables *console* access to the specified bucket, because console requests don't originate from the specified VPC endpoint.

JSON

```
{
```

```

```

For more policy examples, see Endpoints for Amazon S3 in the *VPC User Guide*.

For more information about VPC connectivity, see Network-to-VPC connectivity options in the AWS whitepaper Amazon Virtual Private Cloud Connectivity Options.

Compliance validation for Amazon S3

The security and compliance of Amazon S3 is assessed by third-party auditors as part of multiple AWS compliance programs, including the following:

- System and Organization Controls (SOC)
- Payment Card Industry Data Security Standard (PCI DSS)
- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)

AWS provides a frequently updated list of AWS services in scope of specific compliance programs at AWS Services in Scope by Compliance Program.

Third-party audit reports are available for you to download using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

For more information about AWS compliance programs, see AWS Compliance Programs.

Your compliance responsibility when using Amazon S3 is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. If your use of Amazon S3 is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- Security and Compliance Quick Start Guides that discuss architectural considerations and steps for deploying security- and compliance-focused baseline environments on AWS.
- Architecting for HIPAA Security and Compliance outlines how companies use AWS to help them meet HIPAA requirements.
- AWS Compliance Resources provide several different workbooks and guides that might apply to your industry and location.
- AWS Config can be used to assess how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub provides you with a comprehensive view of your security state within AWS and helps you check your compliance with security industry standards and best practices.
- Locking objects with Object Lock can help you meet technical requirements of financial services regulators (such as the SEC, FINRA, and CFTC) that require write once, read many (WORM) data storage for certain types of books and records information.

- Cataloging and analyzing your data with S3 Inventory can help you audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs.

Resilience in Amazon S3

The AWS global infrastructure is built around Regions and Availability Zones. AWS Regions provide multiple, physically separated and isolated Availability Zones that are connected with low latency, high throughput, and highly redundant networking. These Availability Zones offer you an effective way to design and operate applications and databases. They are more highly available, fault tolerant, and scalable than traditional single data center infrastructures or multi-data center infrastructures. If you specifically need to replicate your data over greater geographic distances, you can use Replicating objects within and across Regions, which enables automatic, asynchronous copying of objects across buckets in different AWS Regions.

Each AWS Region has multiple Availability Zones. You can deploy your applications across multiple Availability Zones in the same Region for fault tolerance and low latency. Availability Zones are connected to each other with fast, private fiber-optic networking, enabling you to easily architect applications that automatically fail over between Availability Zones without interruption.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon S3 offers several features to help support your data resiliency and backup needs.

Lifecycle configuration

A lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. With lifecycle configuration rules, you can tell Amazon S3 to transition objects to less expensive storage classes, archive them, or delete them. For more information, see Managing the lifecycle of objects.

Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see Retaining multiple versions of objects with S3 Versioning.

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements

that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see Locking objects with Object Lock.

Storage classes

Amazon S3 offers a range of storage classes to choose from depending on the requirements of your workload. The S3 Standard-IA and S3 One Zone-IA storage classes are designed for data you access about once a month and need milliseconds access. The S3 Glacier Instant Retrieval storage class is designed for long-lived archive data accessed with milliseconds access that you access about once a quarter. For archive data that does not require immediate access, such as backups, you can use the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see Understanding and managing Amazon S3 storage classes.

The following security best practices also address resilience:

- Enable versioning
- Consider Amazon S3 cross-region replication
- Identify and audit all your Amazon S3 buckets

Encryption of Amazon S3 backups

If you are storing backups using Amazon S3, the encryption of your backups depends on the configuration of those buckets. Amazon S3 provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The default encryption supports keys stored in AWS KMS (SSE-KMS). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.

For more information about Versioning and Object Lock, see the following topics: Retaining multiple versions of objects with S3 Versioning Locking objects with Object Lock

Infrastructure security in Amazon S3

As a managed service, Amazon S3 is protected by the AWS global network security procedures that are described in the security pillar of the AWS Well-Architected Framework.

Access to Amazon S3 through the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend also supporting TLS 1.3 and hybrid post-quantum key exchange. To learn about post-quantum cryptography at AWS, including links to blog posts and research papers, see Post-Quantum Cryptography for AWS.

> **Note**
>
> TLS 1.3 is supported in all S3 endpoints, except for AWS PrivateLink for Amazon S3 and Multi-Region Access Points.

Clients must also support cipher suites with Perfect Forward Secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Additionally, requests must be signed using AWS Signature V4 or AWS Signature V2, requiring valid credentials to be provided.

These APIs are callable from any network location. However, Amazon S3 does support resource-based access policies, which can include restrictions based on the source IP address. You can also use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints, or specific VPCs. Effectively, this isolates network access to a given Amazon S3 bucket from only the specific VPC within the AWS network. For more information, see Controlling access from VPC endpoints with bucket policies.

The following security best practices also address infrastructure security in Amazon S3:

- Consider VPC endpoints for Amazon S3 access
- Identify and audit all your Amazon S3 buckets

Configuration and vulnerability analysis in Amazon S3

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- Compliance validation for Amazon S3
- Shared Responsibility Model
- Amazon Web Services: Overview of Security Processes

The following security best practices also address configuration and vulnerability analysis in Amazon S3:

- Identify and audit all your Amazon S3 buckets
- Enable AWS Config

Access management

Amazon S3 provides a variety of access management tools. The following is a list of these features and tools. You do not need all of these access management tools, but you must use one or more to grant access to your Amazon S3 buckets, objects, and other S3 resources. Proper application of these tools can help make sure that your resources are accessible only to the intended users.

The most commonly used access management tool is an *access policy*. An access policy can be a *resource-based policy* that is attached to an AWS resource, such as a bucket policy for a bucket. An access policy can also be an *identity-based policy* that is attached to an AWS Identity and Access Management (IAM) identity, such as an IAM user, group, or role. An access policy describes who has access to what things. Write an access policy to grant AWS accounts and IAM users, groups, and roles permission to perform operations on a resource. For example, you can grant `PUT Object` permission to another AWS account so that the other account can upload objects to your bucket.

The following are the access management tools available in Amazon S3. For a more comprehensive guide on Amazon S3 access control, see Access control in Amazon S3.

Bucket policy

An Amazon S3 bucket policy is a JSON-formatted AWS Identity and Access Management (IAM) resource-based policy that is attached to a particular bucket. Use bucket policies to grant other

AWS accounts or IAM identities permissions for the bucket and the objects in it. Many S3 access management use cases can be met by using a bucket policy. With bucket policies, you can personalize bucket access to help make sure that only the identities that you have approved can access resources and perform actions within them. For more information, see Bucket policies for Amazon S3.

Identity-based policy

An identity-based or IAM user policy is a type of AWS Identity and Access Management (IAM) policy. An identity-based policy is a JSON-formatted policy that is attached to IAM users, groups, or roles in your AWS account. You can use identity-based policies to grant an IAM identity access to your buckets or objects. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to AWS resources, including Amazon S3 resources. For more information, see Identity-based policies for Amazon S3.

S3 Access Grants

Use S3 Access Grants to create access grants to your Amazon S3 data for both identities in corporate identity directories, such as Active Directory, and to AWS Identity and Access Management (IAM) identities. S3 Access Grants helps you manage data permissions at scale. Additionally, S3 Access Grants logs end-user identity and the application used to access the S3 data in AWS CloudTrail. This provides a detailed audit history down to the end-user identity for all access to the data in your S3 buckets. For more information, see Managing access with S3 Access Grants.

Access Points

Amazon S3 Access Points simplifies managing data access at scale for applications that use shared datasets on S3. Access Points are named network endpoints that are attached to a bucket. You can use access points to perform S3 object operations at scale, such as uploading and retrieving objects. A bucket can have up to 10,000 access points attached, and for each access point, you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. S3 Access Points can be associated with buckets in the same account or in another trusted account. Access Points policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy. For more information, see Managing access to shared datasets with access points.

Access control list (ACL)

An ACL is a list of grants identifying the grantee and the permission granted. ACLs grant basic read or write permissions to other AWS accounts. ACLs use an Amazon S3–specific XML schema. An ACL is a type of AWS Identity and Access Management (IAM) policy. An object ACL is used to manage access to an object, and a bucket ACL is used to manage access to a bucket. With bucket policies, there is a single policy for the entire bucket, but object ACLs are specified for each object. We recommend that you keep ACLs turned off, except in circumstances where you must individually control access for each object. For more information about using ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Warning**
>
> The majority of modern use cases in Amazon S3 do not require the use of ACLs.

Object Ownership

To manage access to your objects, you must be the owner of the object. You can use the Object Ownership bucket-level setting to control ownership of objects uploaded to your bucket. Also, use Object Ownership to turn on ACLs. By default, Object Ownership is set to the *Bucket owner enforced setting* and all ACLs are turned off. When ACLs are turned off, the bucket owner owns all of the objects in the bucket and exclusively manages access to data. To manage access, the bucket owner uses policies or another access management tool, excluding ACLs. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

For a more comprehensive guide on Amazon S3 access control and additional best practices, see Access control in Amazon S3.

Amazon Simple Storage Service data inventory

Amazon S3

Amazon S3 provides scalable object storage in the AWS Cloud. It allows you to store and retrieve any amount of data from anywhere on the web. Based on its unique architecture, S3 is designed to exceed 99.999999999% (11 nines) data durability. Additionally, S3 stores data redundantly across a minimum of 3 Availability Zones by default, providing built-in resilience against widespread disaster. Customers can store data in a single Availability Zone to minimize storage cost or latency, in multiple Availability Zones for resilience against the permanent loss of an entire data center, or in multiple AWS Regions to meet geographic resilience requirements.

Key Characteristics

Geographic location

Amazon S3 is hosted in multiple locations worldwide. You select locations for your data that put them close to your customers.

Buckets

A bucket is a container for objects stored in Amazon S3. Every object is contained within a bucket.

Objects

Objects are the fundamental entities stored in Amazon S3. Objects consist of object data and metadata.

Storage Classes

Amazon S3 offers different storage classes optimized for different use cases.

Storage Management

Amazon S3 has storage management features that you can use to manage costs and adhere to compliance requirements.

Access management and security

Amazon S3 provides features for auditing and managing access to your buckets and objects.

Geographic location

Amazon S3 is available in every AWS Region worldwide. Each Region is a separate geographic area.

Why this matters

After you determine where you want to store your data, you can decide whether to deploy functionally equivalent storage in the same locations or different locations, depending on your needs.

To get a summary of your Amazon S3 buckets across all Regions

Use the following AWS CLI command:

```
aws s3api list-buckets /
 --max-items 100 /
 --page-size 100
```

For more information, see list-buckets in the AWS CLI Command Reference.

Buckets

Amazon S3 buckets are containers for objects. Each bucket has a unique name across all of AWS. Amazon S3 supports four types of buckets: general purpose buckets, Directory buckets, table buckets, and vector buckets. Each type of bucket provides a unique set of features for different use cases. For more information on the different bucket types, see Buckets in the Amazon S3 User Guide.

Why these matter

After you list your buckets, you can validate your buckets settings for functionally equivalent storage systems by reviewing the various bucket configuration settings.

To list bucket configurations

```
aws s3api get-bucket-versioning --bucket amzn-s3-demo-bucket1
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
aws s3api get-bucket-logging --bucket amzn-s3-demo-bucket1
```

For more information, see get-bucket-versioning in the AWS CLI Command Reference.

Objects

Objects are the fundamental entities stored in Amazon S3. Each object consists of data, a key (name), and metadata.

Why these matter

Understanding your object characteristics helps plan for equivalent storage capacity and performance requirements in functionally equivalent systems.

To list objects and their properties

```
aws s3api list-objects-v2 --bucket amzn-s3-demo-bucket1 /
```

```
    --query 'Contents[].{Key: Key, Size: Size, LastModified: LastModified}'
```

For more information, see list-objects-v2 in the AWS CLI Command Reference.

Storage Classes

- Amazon S3 Standard
- Amazon S3 Intelligent-Tiering
- Amazon S3 Standard-IA
- Amazon S3 One Zone-IA
- Amazon S3 Glacier Instant Retrieval
- Amazon S3 Glacier Flexible Retrieval
- Amazon S3 Glacier Deep Archive
- Amazon S3 Express One Zone

Why these matter

Understanding your storage class usage helps determine appropriate storage tiers in functionally equivalent systems. For more information, see Understanding and managing Amazon S3 storage classes in the Amazon S3 User Guide.

To review storage class selection and usage

You can use Amazon S3 Storage Lens to review your storage class selection and usage. For more information, see Understanding and manage Amazon S3 storage classes in the Amazon S3 User Guide.

Storage management

Why this matters

Understanding your storage management usage helps plan for equivalent features to manage costs and adhere to compliance requirements in functionally equivalent systems.

To review storage managment feature selection and usage

You can use Amazon S3 Storage Lens to review your usage of storage management features. For more information, see Amazon S3 Storage Lens metrics glossary in the Amazon S3 User Guide.

Access management and security

Why these matter

Understanding your access management and security settings help you plan for equivalent features to manage access and security requirements in functionally equivalent systems.

To review your access management and security settings

After you list your buckets, you can validate your buckets security and access settings for functionally equivalent storage systems by reviewing the various bucket configuration settings.

```
aws s3api get-public-access-block --bucket amzn-s3-demo-bucket1
aws s3api get-bucket-acl --bucket amzn-s3-demo-bucket1
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
aws s3api get-bucket-policy --bucket amzn-s3-demo-bucket1
```

Data Transfer

You can transfer data from Amazon S3 using several methods:

- AWS CLI
- AWS SDK
- Amazon S3 REST API
- Third-party tools

Example using AWS CLI

To download an entire bucket:

```
aws s3 sync s3://amzn-s3-demo-bucket1 /local/path
```

For more information, see sync in the AWS CLI Command Reference.

To download specific objects:

```
aws s3 cp s3://amzn-s3-demo-bucket1/path/to/object /local/path
```

For more information, see cp in the AWS CLI Command Reference.

Related Resources

The following are additional characteristics of Amazon S3:

- Access control in Amazon S3
- Security in Amazon S3
- Data protection in Amazon S3
- Logging and monitoring in Amazon S3

Data protection in Amazon S3

In addition to the resilience offered by the AWS global infrastructure, Amazon S3 offers a number of features to help protect your data against accidental deletions or Regional failures.

S3 Replication

You can use live replication to enable automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket. To enable failover controls, you can configure replication to be two-way (bidirectional) so that your source and destination buckets can be kept in sync during a Regional failure. For more information, see the section called “Replicating objects within and across Regions”.

Multi-Region Access Points and failover controls

Amazon S3 Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provide built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint use AWS Global Accelerator to automatically route over the AWS global network to the closest-proximity S3 bucket with an active routing status. For more information about Multi-Region Access Points, see the section called “Managing multi-region traffic ”.

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover. If you have S3 Cross-Region Replication (CRR) enabled with

two-way replication rules, you can keep your buckets synchronized during a failover. For more information about failover controls, see the section called “Failover configuration”.

S3 Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see Retaining multiple versions of objects with S3 Versioning.

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see Locking objects with Object Lock.

AWS Backup

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan. For more information, see the section called “Backing up your data”.

For a tutorial on using some of these features together to protect your data, see Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication.

Important

In addition to using the preceding features to protect your data, we recommend reviewing the recommendations in the section called “Security best practices”.

Topics

- Replicating objects within and across Regions

- Managing multi-Region traffic with Multi-Region Access Points
- Retaining multiple versions of objects with S3 Versioning
- Locking objects with Object Lock
- Backing up your Amazon S3 data

Replicating objects within and across Regions

You can use replication to enable automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket.

There are two types of replication: *live replication* and *on-demand replication*.

- **Live replication** – **To automatically replicate new and updated objects** as they are written to the source bucket, use live replication. Live replication doesn't replicate any objects that existed in the bucket before you set up replication. To replicate objects that existed before you set up replication, use on-demand replication.
- **On-demand replication** – **To replicate existing objects** from the source bucket to one or more destination buckets on demand, use S3 Batch Replication. For more information about replicating existing objects, see When to use S3 Batch Replication.

There are two forms of live replication: *Cross-Region Replication (CRR)* and *Same-Region Replication (SRR)*.

- **Cross-Region Replication (CRR)** – You can use CRR to replicate objects across Amazon S3 buckets in different AWS Regions. For more information about CRR, see the section called “When to use Cross-Region Replication”.
- **Same-Region Replication (SRR)** – You can use SRR to copy objects across Amazon S3 buckets in the same AWS Region. For more information about SRR, see the section called “When to use Same-Region Replication”.

Topics

- Why use replication?

- When to use Cross-Region Replication
- When to use Same-Region Replication
- When to use two-way replication (bi-directional replication)
- When to use S3 Batch Replication
- Workload requirements and live replication
- What does Amazon S3 replicate?
- Requirements and considerations for replication
- Setting up live replication overview
- Managing or pausing live replication
- Replicating existing objects with Batch Replication
- Troubleshooting replication
- Monitoring replication with metrics, event notifications, and statuses

Why use replication?

Replication can help you do the following:

- **Replicate objects while retaining metadata** – You can use replication to make copies of your objects that retain all metadata, such as the original object creation times and version IDs. This capability is important if you must ensure that your replica is identical to the source object.
- **Replicate objects into different storage classes** – You can use replication to directly put objects into S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or another storage class in the destination buckets. You can also replicate your data to the same storage class and use lifecycle configurations on the destination buckets to move your objects to a colder storage class as they age.
- **Maintain object copies under different ownership** – Regardless of who owns the source object, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. This is referred to as the *owner override* option. You can use this option to restrict access to object replicas.
- **Keep objects stored over multiple AWS Regions** – To ensure geographic differences in where your data is kept, you can set multiple destination buckets across different AWS Regions. This feature might help you meet certain compliance requirements.
- **Replicate objects within 15 minutes** – To replicate your data in the same AWS Region or across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3

RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called "Using S3 Replication Time Control".

> **Note**
>
> S3 RTC does not apply to Batch Replication. Batch Replication is an on-demand replication job, and can be tracked with S3 Batch Operations. For more information, see Tracking job status and completion reports.

- **Sync buckets, replicate existing objects, and replicate previously failed or replicated objects** – To sync buckets and replicate existing objects, use Batch Replication as an on-demand replication action. For more information about when to use Batch Replication, see When to use S3 Batch Replication.
- **Replicate objects and fail over to a bucket in another AWS Region** – To keep all metadata and objects in sync across buckets during data replication, use two-way replication (also known as bi-directional replication) rules before configuring Amazon S3 Multi-Region Access Point failover controls. Two-way replication rules help ensure that when data is written to the S3 bucket that traffic fails over to, that data is then replicated back to the source bucket.

When to use Cross-Region Replication

S3 Cross-Region Replication (CRR) is used to copy objects across Amazon S3 buckets in different AWS Regions. CRR can help you do the following:

- **Meet compliance requirements** – Although Amazon S3 stores your data across multiple geographically distant Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. To satisfy these requirements, use Cross-Region Replication to replicate data between distant AWS Regions.
- **Minimize latency** – If your customers are in two geographic locations, you can minimize latency in accessing objects by maintaining object copies in AWS Regions that are geographically closer to your users.
- **Increase operational efficiency** – If you have compute clusters in two different AWS Regions that analyze the same set of objects, you might choose to maintain object copies in those Regions.

When to use Same-Region Replication

Same-Region Replication (SRR) is used to copy objects across Amazon S3 buckets in the same AWS Region. SRR can help you do the following:

- **Aggregate logs into a single bucket** – If you store logs in multiple buckets or across multiple accounts, you can easily replicate logs into a single, in-Region bucket. Doing so allows for simpler processing of logs in a single location.
- **Configure live replication between production and test accounts** – If you or your customers have production and test accounts that use the same data, you can replicate objects between those multiple accounts, while maintaining object metadata.
- **Abide by data sovereignty laws** – You might be required to store multiple copies of your data in separate AWS accounts within a certain Region. Same-Region Replication can help you automatically replicate critical data when compliance regulations don't allow the data to leave your country.

When to use two-way replication (bi-directional replication)

- **Build shared datasets across multiple AWS Regions** – With replica modification sync, you can easily replicate metadata changes, such as object access control lists (ACLs), object tags, or object locks, on replication objects. This two-way replication is important if you want to keep all objects and object metadata changes in sync. You can enable replica modification sync on a new or existing replication rule when performing two-way replication between two or more buckets in the same or different AWS Regions.
- **Keep data synchronized across Regions during failover** – You can synchronize data in buckets between AWS Regions by configuring two-way replication rules with S3 Cross-Region Replication (CRR) directly from a Multi-Region Access Point. To make an informed decision on when to initiate failover, you can also enable S3 replication metrics so that you can monitor the replication in Amazon CloudWatch, in S3 Replication Time Control (S3 RTC), or from the Multi-Region Access Point.
- **Make your application highly available** – Even in the event of a Regional traffic disruption, you can use two-way replication rules to keep all metadata and objects in sync across buckets during data replication.

When to use S3 Batch Replication

Batch Replication replicates existing objects to different buckets as an on-demand option. Unlike live replication, these jobs can be run as needed. Batch Replication can help you do the following:

- **Replicate existing objects** – You can use Batch Replication to replicate objects that were added to the bucket before Same-Region Replication or Cross-Region Replication were configured.
- **Replicate objects that previously failed to replicate** – You can filter a Batch Replication job to attempt to replicate objects with a replication status of **FAILED**.
- **Replicate objects that were already replicated** – You might be required to store multiple copies of your data in separate AWS accounts or AWS Regions. Batch Replication can replicate existing objects to newly added destinations.
- **Replicate replicas of objects that were created from a replication rule** – Replication configurations create replicas of objects in destination buckets. Replicas of objects can be replicated only with Batch Replication.

Workload requirements and live replication

Depending on your workload requirements, some types of live replication will be better suited to your use case than others. Use the following table to determine which type of replication to use for your situation, and whether to use S3 Replication Time Control (S3 RTC) for your workload. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement, or SLA). For more information, see the section called “Using S3 Replication Time Control”.

Workload requirement	S3 RTC (15-minute SLA)	Cross-Region Replication (CRR)	Same-Region Replication (SRR)
Replicate objects between different AWS accounts	Yes	Yes	Yes
Replicate objects within the same AWS Region within	No	No	Yes

Workload requirement	S3 RTC (15-minute SLA)	Cross-Region Replication (CRR)	Same-Region Replication (SRR)
24-48 hours (not SLA backed)			
Replicate objects between different AWS Regions within 24-48 hours (not SLA backed)	No	Yes	No
Predictable replication time: Backed by SLA to replicate 99.9 percent of objects within 15 minutes	Yes	No	No

What does Amazon S3 replicate?

Amazon S3 replicates only specific items in buckets that are configured for replication.

Topics

- What is replicated with replication configurations?
- What isn't replicated with replication configurations?

What is replicated with replication configurations?

By default, Amazon S3 replicates the following:

- Objects created after you add a replication configuration.
- Unencrypted objects.
- Objects encrypted using customer provided keys (SSE-C), objects encrypted at rest under an Amazon S3 managed key (SSE-S3) or a KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see the section called “Replicating encrypted objects”.

- Object metadata from the source objects to the replicas. For information about replicating metadata from the replicas to the source objects, see Replicating metadata changes with replica modification sync.
- Only objects in the source bucket for which the bucket owner has permissions to read objects and access control lists (ACLs).

  For more information about resource ownership, see Amazon S3 bucket and object ownership.
- Object ACL updates, unless you direct Amazon S3 to change the replica ownership when source and destination buckets aren't owned by the same accounts.

  For more information, see Changing the replica owner.

  It can take a while until Amazon S3 can bring the two ACLs in sync. This change in ownership applies only to objects created after you add a replication configuration to the bucket.
- Object tags, if there are any.
- Object annotations, if there are any. Each annotation replicates independently as changes occur during live replication. During S3 Batch Replication, annotations are replicated independently alongside the object, but there are no separate job tasks for individual annotations. If annotation replication fails, the job task fails, but the object's replication status does not reflect the annotation failure.
- S3 Object Lock retention information, if there is any.

  When Amazon S3 replicates objects that have retention information applied, it applies those same retention controls to your replicas, overriding the default retention period configured on your destination buckets. If you don't have retention controls applied to the objects in your source bucket, and you replicate into destination buckets that have a default retention period set, the destination bucket's default retention period is applied to your object replicas. For more information, see Locking objects with Object Lock.

How delete operations affect replication

If you delete an object from the source bucket, the following actions occur by default:

- If you make a DELETE request without specifying an object version ID, Amazon S3 adds a delete marker. Amazon S3 deals with the delete marker as follows:
  - If you are using the latest version of the replication configuration (that is, you specify the `Filter` element in a replication configuration rule), Amazon S3 does not replicate the delete

marker by default. However, you can add *delete marker replication* to non-tag-based rules. For more information, see Replicating delete markers between buckets.

- If you don't specify the `Filter` element, Amazon S3 assumes that the replication configuration is version V1, and it replicates delete markers that resulted from user actions. However, if Amazon S3 deletes an object due to a lifecycle action, the delete marker is not replicated to the destination buckets.

- If you specify an object version ID to delete in a `DELETE` request, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination buckets. In other words, it doesn't delete the same object version from the destination buckets. This protects data from malicious deletions.

What isn't replicated with replication configurations?

By default, Amazon S3 doesn't replicate the following:

- Objects in the source bucket that are replicas that were created by another replication rule. For example, suppose you configure replication where bucket A is the source and bucket B is the destination. Now suppose that you add another replication configuration where bucket B is the source and bucket C is the destination. In this case, objects in bucket B that are replicas of objects in bucket A are not replicated to bucket C.

  To replicate objects that are replicas, use Batch Replication. Learn more about configuring Batch Replication at Replicating existing objects.

- Objects in the source bucket that have already been replicated to a different destination. For example, if you change the destination bucket in an existing replication configuration, Amazon S3 won't replicate the objects again.

  To replicate previously replicated objects, use Batch Replication. Learn more about configuring Batch Replication at Replicating existing objects.

- Batch Replication does not support re-replicating objects that were deleted with the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and initiates replication automatically to the destination. For more information about how to use Batch Copy, see, Examples that use Batch Operations to copy objects.

- By default, when replicating from a different AWS account, delete markers added to the source bucket are not replicated.

  For information about how to replicate delete markers, see Replicating delete markers between buckets.

- Objects that are stored in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access, or S3 Intelligent-Tiering Deep Archive Access storage classes or tiers. You cannot replicate these objects until you restore them and copy them to a different storage class.

  To learn more about S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive, see Storage classes for rarely accessed objects.

  To learn more about the S3 Intelligent-Tiering, see Managing storage costs with Amazon S3 Intelligent-Tiering.

- Objects in the source bucket that the bucket owner doesn't have sufficient permissions to replicate.

  For information about how an object owner can grant permissions to a bucket owner, see Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control.

- Updates to bucket-level subresources.

  For example, if you change the lifecycle configuration or add a notification configuration to your source bucket, these changes are not applied to the destination bucket. This feature makes it possible to have different configurations on source and destination buckets.

- Actions performed by lifecycle configuration.
