  For example, if lifecycle configuration is enabled only on your source bucket, Amazon S3 creates delete markers for expired objects but doesn't replicate those markers. If you want the same lifecycle configuration applied to both the source and destination buckets, enable the same lifecycle configuration on both. For more information about lifecycle configuration, see Managing the lifecycle of objects.

- When you're using tag-based replication rules with live replication, new objects must be tagged with the matching replication rule tag in the `PutObject` operation. Otherwise, the objects won't be replicated. If objects are tagged after the `PutObject` operation, those objects also won't be replicated.

To replicate objects that have been tagged after the `PutObject` operation, you must use S3 Batch Replication. For more information about Batch Replication, see Replicating existing objects.

- Annotation deletions on the source bucket are not replicated to the destination. If you delete an annotation on the source, the annotation persists on the replica. You cannot exclude annotations from replication using replication rule filters. When replication is configured, all annotation creates and updates are replicated unless the replication role policy explicitly denies `s3:ReplicateObjectAnnotation`.

  If annotations are repeatedly deleted and recreated on the source with different names, the destination replica accumulates annotations over time because deletions are not replicated. This accumulation can eventually cause the destination to exceed the 1,000 annotation limit per object version.

  Annotation overwrites (updates to an existing annotation name) at the source are replicated to the destination. The destination annotation content stays current with the source.

Requirements and considerations for replication

Amazon S3 replication requires the following:

- The source bucket owner must have the source and destination AWS Regions enabled for their account. The destination bucket owner must have the destination Region enabled for their account.

  For more information about enabling or disabling an AWS Region, see Specify which AWS Regions your account can use in the *AWS Account Management Reference Guide*.
- Both source and destination buckets must have versioning enabled. For more information about versioning, see Retaining multiple versions of objects with S3 Versioning.
- Amazon S3 must have permissions to replicate objects from the source bucket to the destination bucket or buckets on your behalf. For more information about these permissions, see Setting up permissions for live replication.
- If the owner of the source bucket doesn't own the object in the bucket, the object owner must grant the bucket owner `READ` and `READ_ACP` permissions with the object access control list (ACL). For more information, see Access control list (ACL) overview.

- If the source bucket has S3 Object Lock enabled, the destination buckets must also have S3 Object Lock enabled.

  To enable replication on a bucket that has Object Lock enabled, you must use the AWS Command Line Interface, REST API, or AWS SDKs. For more general information, see Locking objects with Object Lock.

  > **Note**
  >
  > You must grant two new permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two new permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission, it satisfies the requirement. For more information, see Setting up permissions for live replication.

For more information, see Setting up live replication overview.

If you are setting the replication configuration in a *cross-account scenario*, where the source and destination buckets are owned by different AWS accounts, the following additional requirement applies:

- The owner of the destination buckets must grant the owner of the source bucket permissions to replicate objects with a bucket policy. For more information, see (Optional) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts.
- The destination buckets cannot be configured as Requester Pays buckets. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.

Considerations for replication

Before you create a replication configuration, be aware of the following considerations.

Topics

- Lifecycle configuration and object replicas
- Managing incomplete multipart uploads in destination buckets
- Versioning configuration and replication configuration
- Using S3 Replication with S3 Intelligent-Tiering

- Logging configuration and replication configuration
- CRR and the destination Region
- S3 Batch Replication
- S3 Replication Time Control

Lifecycle configuration and object replicas

The time it takes for Amazon S3 to replicate an object depends on the size of the object. For large objects, it can take several hours. Although it might take a while before a replica is available in the destination, it takes the same amount of time to create the replica as it took to create the corresponding object in the source bucket. If a lifecycle configuration is enabled on a destination bucket, the lifecycle rules honor the original creation time of the object, not when the replica became available in the destination bucket.

Replication configuration requires the bucket to be versioning-enabled. When you enable versioning on a bucket, keep the following in mind:

- If you have an object Expiration lifecycle configuration, after you enable versioning, add a `NonCurrentVersionExpiration` policy to maintain the same permanent delete behavior as before you enabled versioning.
- If you have a Transition lifecycle configuration, after you enable versioning, consider adding a `NonCurrentVersionTransition` policy.

You can also use an S3 Lifecycle rule to manage incomplete multipart uploads in destination buckets. For more information, see Managing incomplete multipart uploads in destination buckets.

Managing incomplete multipart uploads in destination buckets

When a source object was uploaded with multipart upload, Amazon S3 replicates it to the destination bucket with multipart upload. As with any multipart upload, if the upload isn't completed, its parts remain in the destination bucket until the upload is stopped. As a best practice, we recommend that you configure an S3 Lifecycle rule on the destination bucket by using the `AbortIncompleteMultipartUpload` action to minimize your storage costs. For more information, see Configuring a bucket lifecycle configuration to delete incomplete multipart uploads.

Versioning configuration and replication configuration

Both the source and destination buckets must be versioning-enabled when you configure replication on a bucket. After you enable versioning on both the source and destination buckets and configure replication on the source bucket, you will encounter the following issues:

- If you attempt to disable versioning on the source bucket, Amazon S3 returns an error. You must remove the replication configuration before you can disable versioning on the source bucket.
- If you disable versioning on the destination bucket, replication fails. The source object has the replication status `FAILED`.

Using S3 Replication with S3 Intelligent-Tiering

S3 Intelligent-Tiering is a storage class that is designed to optimize storage costs by automatically moving data to the most cost-effective access tier. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

Replicating objects stored in S3 Intelligent-Tiering with S3 Batch Replication or invoking CopyObject or UploadPartCopy constitutes access. In these cases, the source objects of the copy or replication operations are tiered up.

For more information about S3 Intelligent-Tiering see, Managing storage costs with Amazon S3 Intelligent-Tiering.

Logging configuration and replication configuration

If Amazon S3 delivers logs to a bucket that has replication enabled, it replicates the log objects.

If server access logs or AWS CloudTrail logs are enabled on your source or destination bucket, Amazon S3 includes replication-related requests in the logs. For example, Amazon S3 logs each object that it replicates.

CRR and the destination Region

Amazon S3 Cross-Region Replication (CRR) is used to copy objects across S3 buckets in different AWS Regions. You might choose the Region for your destination bucket based on either your business needs or cost considerations. For example, inter-Region data transfer charges vary depending on the Regions that you choose.

Suppose that you chose US East (N. Virginia) (`us-east-1`) as the Region for your source bucket. If you choose US West (Oregon) (`us-west-2`) as the Region for your destination buckets, you pay more than if you choose the US East (Ohio) (`us-east-2`) Region. For pricing information, see "Data Transfer Pricing" in Amazon S3 pricing.

There are no data transfer charges associated with Same-Region Replication (SRR).

S3 Batch Replication

For information about considerations for Batch Replication, see S3 Batch Replication considerations.

S3 Replication Time Control

For information about best practices and considerations for S3 Replication Time Control (S3 RTC), see Best practices and guidelines for S3 RTC.

Setting up live replication overview

> **Note**
>
> Objects that existed before you set up replication aren't replicated automatically. In other words, Amazon S3 doesn't replicate objects retroactively. To replicate objects that were created before your replication configuration, use S3 Batch Replication. For more information about configuring Batch Replication, see Replicating existing objects.

To enable live replication—Same-Region Replication (SRR) or Cross-Region Replication (CRR)—add a replication configuration to your source bucket. This configuration tells Amazon S3 to replicate objects as specified. In the replication configuration, you must provide the following:

- **The destination buckets** – The bucket or buckets where you want Amazon S3 to replicate the objects.
- **The objects that you want to replicate** – You can replicate all objects in the source bucket or a subset of objects. You identify a subset by providing a key name prefix, one or more object tags, or both in the configuration.

  For example, if you configure a replication rule to replicate only objects with the key name prefix `Tax/`, Amazon S3 replicates objects with keys such as `Tax/doc1` or `Tax/doc2`. But it doesn't

replicate objects with the key `Legal/doc3`. If you specify both a prefix and one or more tags, Amazon S3 replicates only objects that have the specific key prefix and tags.

- **An AWS Identity and Access Management (IAM) role** – Amazon S3 assumes this IAM role to replicate objects on your behalf. For more information about creating this IAM role and managing permissions, see Setting up permissions for live replication.

In addition to these minimum requirements, you can choose the following options:

- **Replica storage class** – By default, Amazon S3 stores object replicas using the same storage class as the source object. You can specify a different storage class for the replicas.
- **Replica ownership** – Amazon S3 assumes that an object replica continues to be owned by the owner of the source object. So when it replicates objects, it also replicates the corresponding object access control list (ACL) or S3 Object Ownership setting. If the source and destination buckets are owned by different AWS accounts, you can configure replication to change the owner of a replica to the AWS account that owns the destination bucket. For more information, see the section called “Changing the replica owner”.

You can configure replication by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API. For detailed walkthroughs of how to set up replication, see the section called “Replication walkthroughs”.

Amazon S3 provides REST API operations to support setting up replication rules. For more information, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PutBucketReplication
- GetBucketReplication
- DeleteBucketReplication

Topics

- Replication configuration file elements
- Setting up permissions for live replication
- Examples for configuring live replication

Replication configuration file elements

Amazon S3 stores a replication configuration as XML. If you're configuring replication programmatically through the Amazon S3 REST API, you specify the various elements of your replication configuration in this XML file. If you're configuring replication through the AWS Command Line Interface (AWS CLI), you specify your replication configuration using JSON format. For JSON examples, see the walkthroughs in the section called “Replication walkthroughs”.

> **Note**
>
> The latest version of the replication configuration XML format is V2. XML V2 replication configurations are those that contain the `<Filter>` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).
>
> To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see GetBucketReplication in the *Amazon Simple Storage Service API Reference*.
>
> For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration format. If you've used the XML V1 replication configuration format, see Backward compatibility considerations for backward compatibility considerations.

In the replication configuration XML file, you must specify an AWS Identity and Access Management (IAM) role and one or more rules, as shown in the following example:

```
<ReplicationConfiguration>
    <Role>IAM-role-ARN</Role>
    <Rule>
        ...
    </Rule>
    <Rule>
         ...
    </Rule>
     ...
</ReplicationConfiguration>
```

Amazon S3 can't replicate objects without your permission. You grant permissions to Amazon S3 with the IAM role that you specify in the replication configuration. Amazon S3 assumes this IAM role to replicate objects on your behalf. You must grant the required permissions to the IAM

role first. For more information about managing permissions, see Setting up permissions for live replication.

An Amazon S3 replication configuration can have up to 1,000 rules per source bucket. This limit is not adjustable.

You add only one rule in a replication configuration in the following scenarios:

- You want to replicate all objects.
- You want to replicate only one subset of objects. You identify the object subset by adding a filter in the rule. In the filter, you specify an object key prefix, tags, or a combination of both to identify the subset of objects that the rule applies to. The filters target objects that match the exact values that you specify.

If you want to replicate different subsets of objects, you add multiple rules in a replication configuration. In each rule, you specify a filter that selects a different subset. For example, you might choose to replicate objects that have either `tax/` or `document/` key prefixes. To do this, you add 2 rules, one that specifies the `tax/` key prefix filter and another that specifies the `document/` key prefix. For more information about object key prefixes, see Organizing objects using prefixes.

The following sections provide additional information.

Topics

- Basic rule configuration
- Optional: Specifying a filter
- Additional destination configurations
- Example replication configurations
- Backward compatibility considerations

Basic rule configuration

Each rule must include the rule's status and priority. The rule must also indicate whether to replicate delete markers.

- The `<Status>` element indicates whether the rule is enabled or disabled by using the values `Enabled` or `Disabled`. If a rule is disabled, Amazon S3 doesn't perform the actions specified in the rule.

- The <Priority> element indicates which rule has precedence whenever 2 or more replication rules conflict. Amazon S3 attempts to replicate objects according to all replication rules. However, if there are 2 or more rules with the same destination bucket, then objects are replicated according to the rule with the highest priority. The higher the number, the higher the priority.
- The <DeleteMarkerReplication> element indicates whether to replicate delete markers by using the values Enabled or Disabled.

In the <Destination> element configuration, you must provide the name of the destination bucket or buckets where you want Amazon S3 to replicate objects.

The following example shows the minimum requirements for a V2 rule. For backward compatibility, Amazon S3 continues to support the XML V1 format. For more information, see Backward compatibility considerations.

```
...
    <Rule>
        <ID>Rule-1</ID>
        <Status>Enabled-or-Disabled</Status>
        <Filter>
            <Prefix></Prefix>
        </Filter>
        <Priority>integer</Priority>
        <DeleteMarkerReplication>
           <Status>Enabled-or-Disabled</Status>
        </DeleteMarkerReplication>
        <Destination>
           <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
        </Destination>
    </Rule>
    <Rule>
         ...
    </Rule>
     ...
...
```

You can also specify other configuration options. For example, you might choose to use a storage class for object replicas that differs from the class for the source object.

Optional: Specifying a filter

To choose a subset of objects that the rule applies to, add an optional filter. You can filter by object key prefix, object tags, or a combination of both. If you filter on both a key prefix and object tags, Amazon S3 combines the filters by using a logical AND operator. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

Filter based on object key prefix

To specify a rule with a filter based on an object key prefix, use the following XML. You can specify only one prefix per rule.

```
<Rule>
    ...
    <Filter>
        <Prefix>key-prefix</Prefix>
    </Filter>
    ...
</Rule>
...
```

Filter based on object tags

To specify a rule with a filter based on object tags, use the following XML. You can specify one or more object tags.

```
<Rule>
    ...
    <Filter>
        <And>
            <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
            </Tag>
            <Tag>
                <Key>key2</Key>
                <Value>value2</Value>
            </Tag>
             ...
        </And>
    </Filter>
    ...
```

```
</Rule>
...
```

Filter with a key prefix and object tags

To specify a rule filter with a combination of a key prefix and object tags, use the following XML. You wrap these filters in an <And> parent element. Amazon S3 performs a logical AND operation to combine these filters. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

```
<Rule>
    ...
    <Filter>
        <And>
            <Prefix>key-prefix</Prefix>
            <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
            </Tag>
            <Tag>
                <Key>key2</Key>
                <Value>value2</Value>
            </Tag>
             ...
    </Filter>
    ...
</Rule>
...
```

Note

- If you specify a rule with an empty <Filter> element, your rule applies to all objects in your bucket.
- When you're using tag-based replication rules with live replication, new objects must be tagged with the matching replication rule tag in the PutObject operation. Otherwise, the objects won't be replicated. If objects are tagged after the PutObject operation, those objects also won't be replicated.

To replicate objects that have been tagged after the `PutObject` operation, you must use S3 Batch Replication. For more information about Batch Replication, see Replicating existing objects.

Additional destination configurations

In the destination configuration, you specify the bucket or buckets where you want Amazon S3 to replicate objects. You can set configurations to replicate objects from one source bucket to one or more destination buckets.

```
...
<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>
...
```

You can add the following options in the `<Destination>` element.

Topics

- Specify storage class
- Add multiple destination buckets
- Specify different parameters for each replication rule with multiple destination buckets
- Change replica ownership
- Enable S3 Replication Time Control
- Replicate objects created with server-side encryption by using AWS KMS

Specify storage class

You can specify the storage class for the object replicas. By default, Amazon S3 uses the storage class of the source object to create object replicas, as in the following example.

```
...
<Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
       <StorageClass>storage-class</StorageClass>
</Destination>
```

```
...
```

Add multiple destination buckets

You can add multiple destination buckets in a single replication configuration, as follows.

```
...
<Rule>
    <ID>Rule-1</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
       <Status>Enabled-or-Disabled</Status>
    </DeleteMarkerReplication>
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket1</Bucket>
    </Destination>
</Rule>
<Rule>
    <ID>Rule-2</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
       <Status>Enabled-or-Disabled</Status>
    </DeleteMarkerReplication>
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket2</Bucket>
    </Destination>
</Rule>
...
```

Specify different parameters for each replication rule with multiple destination buckets

When adding multiple destination buckets in a single replication configuration, you can specify different parameters for each replication rule, as follows.

```
...
<Rule>
    <ID>Rule-1</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
       <Status>Disabled</Status>
```

```
    </DeleteMarkerReplication>
      <Metrics>
    <Status>Enabled</Status>
    <EventThreshold>
      <Minutes>15</Minutes>
    </EventThreshold>
  </Metrics>
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket1</Bucket>
    </Destination>
</Rule>
<Rule>
    <ID>Rule-2</ID>
    <Status>Enabled-or-Disabled</Status>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
       <Status>Enabled</Status>
    </DeleteMarkerReplication>
      <Metrics>
    <Status>Enabled</Status>
    <EventThreshold>
      <Minutes>15</Minutes>
    </EventThreshold>
  </Metrics>
  <ReplicationTime>
    <Status>Enabled</Status>
    <Time>
      <Minutes>15</Minutes>
    </Time>
  </ReplicationTime>
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket2</Bucket>
    </Destination>
</Rule>
...
```

Change replica ownership

When the source and destination buckets aren't owned by the same accounts, you can change the ownership of the replica to the AWS account that owns the destination bucket. To do so, add the `<AccessControlTranslation>` element. This element takes the value `Destination`.

```
...
```

```
<Destination>
   <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
   <Account>destination-bucket-owner-account-id</Account>
   <AccessControlTranslation>
       <Owner>Destination</Owner>
   </AccessControlTranslation>
</Destination>
...
```

If you don't add the <AccessControlTranslation> element to the replication configuration, the replicas are owned by the same AWS account that owns the source object. For more information, see Changing the replica owner.

Enable S3 Replication Time Control

You can enable S3 Replication Time Control (S3 RTC) in your replication configuration. S3 RTC replicates most objects in seconds and 99.99 percent of objects within 15 minutes (backed by a service-level agreement).

> **Note**
>
> Only a value of <Minutes>15</Minutes> is accepted for the <EventThreshold> and <Time> elements.

```
...
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <Metrics>
    <Status>Enabled</Status>
    <EventThreshold>
      <Minutes>15</Minutes>
    </EventThreshold>
  </Metrics>
  <ReplicationTime>
    <Status>Enabled</Status>
    <Time>
      <Minutes>15</Minutes>
    </Time>
  </ReplicationTime>
</Destination>
```

```
...
```

For more information, see Meeting compliance requirements with S3 Replication Time Control. For API examples, see PutBucketReplication in the *Amazon Simple Storage Service API Reference*.

Replicate objects created with server-side encryption by using AWS KMS

Your source bucket might contain objects that were created with server-side encryption by using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, Amazon S3 doesn't replicate these objects. You can optionally direct Amazon S3 to replicate these objects. To do so, first explicitly opt into this feature by adding the `<SourceSelectionCriteria>` element. Then provide the AWS KMS key (for the AWS Region of the destination bucket) to use for encrypting object replicas. The following example shows how to specify these elements.

```
...
<SourceSelectionCriteria>
  <SseKmsEncryptedObjects>
    <Status>Enabled</Status>
  </SseKmsEncryptedObjects>
</SourceSelectionCriteria>
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <EncryptionConfiguration>
    <ReplicaKmsKeyID>AWS KMS key ID to use for encrypting object replicas</
ReplicaKmsKeyID>
  </EncryptionConfiguration>
</Destination>
...
```

For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).

Example replication configurations

To get started, you can add the following example replication configurations to your bucket, as appropriate.

> **Important**
>
> To add a replication configuration to a bucket, you must have the `iam:PassRole` permission. This permission allows you to pass the IAM role that grants Amazon S3 replication permissions. You specify the IAM role by providing the Amazon Resource Name

(ARN) that is used in the <Role> element in the replication configuration XML. For more information, see Granting a User Permissions to Pass a Role to an AWS service in the *IAM User Guide*.

Example 1: Replication configuration with one rule

The following basic replication configuration specifies one rule. The rule specifies an IAM role that Amazon S3 can assume and a single destination bucket for object replicas. The <Status> element value of Enabled indicates that the rule is in effect.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>

    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

To choose a subset of objects to replicate, you can add a filter. In the following configuration, the filter specifies an object key prefix. This rule applies to objects that have the prefix *Tax/* in their key names.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
       <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
       <Prefix>Tax/</Prefix>
    </Filter>
```

```
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>

  </Rule>
</ReplicationConfiguration>
```

If you specify the <Filter> element, you must also include the <Priority> and <DeleteMarkerReplication> elements. In this example, the value that you set for the <Priority> element is irrelevant because there is only one rule.

In the following configuration, the filter specifies 1 prefix and 2 tags. The rule applies to the subset of objects that have the specified key prefix and tags. Specifically, it applies to objects that have the *Tax/* prefix in their key names and the 2 specified object tags. In this example, the value that you set for the <Priority> element is irrelevant because there is only one rule.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
       <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
        <And>
          <Prefix>Tax/</Prefix>
          <Tag>
             <Tag>
                <Key>tagA</Key>
                <Value>valueA</Value>
             </Tag>
          </Tag>
          <Tag>
             <Tag>
                <Key>tagB</Key>
                <Value>valueB</Value>
             </Tag>
          </Tag>
       </And>
```

```
    </Filter>

    <Destination>
        <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>

  </Rule>
</ReplicationConfiguration>
```

You can specify a storage class for the object replicas as follows:

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
       <StorageClass>storage-class</StorageClass>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

You can specify any storage class that Amazon S3 supports.

Example 2: Replication configuration with 2 rules

Example

In the following replication configuration, the rules specify the following:

- Each rule filters on a different key prefix so that each rule applies to a distinct subset of objects. In this example, Amazon S3 replicates objects with the key names *Tax/doc1.pdf* and *Project/project1.txt*, but it doesn't replicate objects with the key name *PersonalDoc/documentA*.
- Although both rules specify a value for the `<Priority>` element, the rule priority is irrelevant because the rules apply to 2 distinct sets of objects. The next example shows what happens when rule priority is applied.

- The second rule specifies the S3 Standard-IA storage class for object replicas. Amazon S3 uses the specified storage class for those object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
       <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
        <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
     ...
  </Rule>
 <Rule>
    <Status>Enabled</Status>
    <Priority>2</Priority>
    <DeleteMarkerReplication>
       <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
        <Prefix>Project</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
     <StorageClass>STANDARD_IA</StorageClass>
    </Destination>
     ...
  </Rule>

</ReplicationConfiguration>
```

Example 3: Replication configuration with 2 rules with overlapping prefixes

In this configuration, the 2 rules specify filters with overlapping key prefixes, *star* and *starship*. Both rules apply to objects with the key name *starship-x*. In this case, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority.

```
<ReplicationConfiguration>

  <Role>arn:aws:iam::account-id:role/role-name</Role>

  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
       <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
        <Prefix>star</Prefix>
    </Filter>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
  <Rule>
    <Status>Enabled</Status>
    <Priority>2</Priority>
    <DeleteMarkerReplication>
       <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
        <Prefix>starship</Prefix>
    </Filter>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

Example 4: Example walkthroughs

For example walkthroughs, see Examples for configuring live replication.

For more information about the XML structure of replication configuration, see PutBucketReplication in the *Amazon Simple Storage Service API Reference*.

Backward compatibility considerations

The latest version of the replication configuration XML format is V2. XML V2 replication configurations are those that contain the `<Filter>` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).

To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see GetBucketReplication in the *Amazon Simple Storage Service API Reference*.

For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration format. If you've used the XML V1 replication configuration format, consider the following issues that affect backward compatibility:

- The replication configuration XML V2 format includes the `<Filter>` element for rules. With the `<Filter>` element, you can specify object filters based on the object key prefix, tags, or both to scope the objects that the rule applies to. The replication configuration XML V1 format supports filtering based only on the key prefix. In that case, you add the `<Prefix>` element directly as a child element of the `<Rule>` element, as in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Prefix>key-prefix</Prefix>
    <Destination>
       <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>

  </Rule>
</ReplicationConfiguration>
```

- When you delete an object from your source bucket without specifying an object version ID, Amazon S3 adds a delete marker. If you use the replication configuration XML V1 format, Amazon S3 replicates only delete markers that result from user actions. In other words, Amazon S3 replicates the delete marker only if a user deletes an object. If an expired object is removed by Amazon S3 (as part of a lifecycle action), Amazon S3 doesn't replicate the delete marker.

In the replication configuration XML V2 format, you can enable delete marker replication for non-tag-based rules. For more information, see Replicating delete markers between buckets.

Setting up permissions for live replication

When setting up live replication in Amazon S3, you must acquire the necessary permissions as follows:

- You must grant the AWS Identity and Access Management (IAM) principal (user or role) who will be creating replication rules a certain set of permissions.
- Amazon S3 needs permissions to replicate objects on your behalf. You grant these permissions by creating an IAM role and then specifying that role in your replication configuration.
- When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also grant the source bucket owner permissions to store the replicas.

> **Note**
>
> If you're using S3 Batch Operations to replicate objects on demand instead of setting up live replication, a different IAM role and policies are required for S3 Batch Replication. For a Batch Replication IAM role and policy examples, see Configuring an IAM role for S3 Batch Replication.

Topics

- Step 1: Granting permissions to the IAM principal who's creating replication rules
- Step 2: Creating an IAM role for Amazon S3 to assume
- (Optional) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts
- (Optional) Step 4: Granting permissions to change replica ownership

Step 1: Granting permissions to the IAM principal who's creating replication rules

The IAM user or role that you will use to create replication rules needs permissions to create replication rules for one- or two-way replications. If the user or role doesn't have these

permissions, you won't be able to create replication rules. For more information, see IAM Identities in the *IAM User Guide*.

The user or role needs the following actions:

- `iam:AttachRolePolicy`
- `iam:CreatePolicy`
- `iam:CreateServiceLinkedRole`
- `iam:PassRole`
- `iam:PutRolePolicy`
- `s3:GetBucketVersioning`
- `s3:GetObjectVersionAcl`
- `s3:GetObjectVersionForReplication`
- `s3:GetReplicationConfiguration`
- `s3:PutReplicationConfiguration`

Following is a sample IAM policy that includes these actions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetAccessPoint",
                "s3:GetAccountPublicAccessBlock",
                "s3:GetBucketAcl",
                "s3:GetBucketLocation",
                "s3:GetBucketPolicyStatus",
                "s3:GetBucketPublicAccessBlock",
                "s3:ListAccessPoints",
                "s3:ListAllMyBuckets",
                "s3:PutReplicationConfiguration",
                "s3:GetReplicationConfiguration",
                "s3:GetBucketVersioning",
```

```
                "s3:GetObjectVersionForReplication",
                "s3:GetObjectVersionAcl",
                "s3:GetObject",
                "s3:ListBucket",
                "s3:GetObjectVersion",
                "s3:GetBucketOwnershipControls",
                "s3:PutBucketOwnershipControls",
                "s3:GetObjectLegalHold",
                "s3:GetObjectRetention",
                "s3:GetBucketObjectLockConfiguration"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1-*",
                "arn:aws:s3:::amzn-s3-demo-bucket2-*/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:List*AccessPoint*",
                "s3:GetMultiRegion*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:Get*",
                "iam:CreateServiceLinkedRole",
                "iam:CreateRole",
                "iam:PassRole"
            ],
            "Resource": "arn:aws:iam::*:role/service-role/s3*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:List*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "iam:AttachRolePolicy",
                "iam:PutRolePolicy",
                "iam:CreatePolicy"
            ],
            "Resource": [
                "arn:aws:iam::*:policy/service-role/s3*",
                "arn:aws:iam::*:role/service-role/s3*"
            ]
        }
    ]
}
```

Step 2: Creating an IAM role for Amazon S3 to assume

By default, all Amazon S3 resources—buckets, objects, and related subresources—are private, and only the resource owner can access the resource. Amazon S3 needs permissions to read and replicate objects from the source bucket. You grant these permissions by creating an IAM role and specifying that role in your replication configuration.

This section explains the trust policy and the minimum required permissions policy that are attached to this IAM role. The example walkthroughs provide step-by-step instructions to create an IAM role. For more information, see Examples for configuring live replication.

> **Note**
>
> If you're using the console to create your replication configuration, we recommend that you skip this section and instead have the console create this IAM role and the necessary trust and permission policies for you.

The *trust policy* identifies which principal identities can assume the IAM role. The *permissions policy* specifies which actions the IAM role can perform, on which resources, and under what conditions.

- The following example shows a *trust policy* where you identify Amazon S3 as the AWS service principal that can assume the role:

  JSON

```
{
```

```
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Service":"s3.amazonaws.com"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

- The following example shows a *trust policy* where you identify Amazon S3 and S3 Batch Operations as service principals that can assume the role. Use this approach if you're creating a Batch Replication job. For more information, see Create a Batch Replication job for new replication rules or destinations.

  JSON

  ```
  {
     "Version":"2012-10-17",
     "Statement":[
        {
           "Effect":"Allow",
           "Principal":{
              "Service": [
                "s3.amazonaws.com",
                "batchoperations.s3.amazonaws.com"
              ]
           },
           "Action":"sts:AssumeRole"
        }
     ]
  }
  ```

  For more information about IAM roles, see IAM roles in the *IAM User Guide*.

- The following example shows the *permissions policy*, where you grant the IAM role permissions to perform replication tasks on your behalf. When Amazon S3 assumes the role, it has the permissions that you specify in this policy. In this policy, *`amzn-s3-demo-source-bucket`* is the source bucket, and *`amzn-s3-demo-destination-bucket`* is the destination bucket.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetReplicationConfiguration",
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-source-bucket"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetObjectVersionForReplication",
            "s3:GetObjectVersionAcl",
            "s3:GetObjectVersionTagging"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:ReplicateObject",
            "s3:ReplicateDelete",
            "s3:ReplicateTags"
         ],
         "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      }
   ]
}
```

The permissions policy grants permissions for the following actions:

- `s3:GetReplicationConfiguration` and `s3:ListBucket` – Permissions for these actions on the *amzn-s3-demo-source-bucket* bucket allow Amazon S3 to retrieve the replication

configuration and list the bucket content. (The current permissions model requires the `s3:ListBucket` permission for accessing delete markers.)

- `s3:GetObjectVersionForReplication` and `s3:GetObjectVersionAcl` – Permissions for these actions are granted on all objects to allow Amazon S3 to get a specific object version and access control list (ACL) associated with the objects.

- `s3:ReplicateObject` and `s3:ReplicateDelete` – Permissions for these actions on all objects in the *amzn-s3-demo-destination-bucket* bucket allow Amazon S3 to replicate objects or delete markers to the destination bucket. For information about delete markers, see How delete operations affect replication.

  > **Note**
  >
  > Permissions for the `s3:ReplicateObject` action on the *amzn-s3-demo-destination-bucket* bucket also allow replication of metadata such as object tags and ACLs. Therefore, you don't need to explicitly grant permission for the `s3:ReplicateTags` action.

- `s3:GetObjectVersionTagging` – Permissions for this action on objects in the *amzn-s3-demo-source-bucket* bucket allow Amazon S3 to read object tags for replication. For more information about object tags, see Tagging your objects. If Amazon S3 doesn't have the `s3:GetObjectVersionTagging` permission, it replicates the objects, but not the object tags.
- `s3:GetObjectVersionAnnotationForReplication` – Permissions for this action on objects in the source bucket allow Amazon S3 to read annotations for replication. If Amazon S3 doesn't have this permission, annotation replication fails. For more information about annotations, see Annotating your objects.

For a list of Amazon S3 actions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

> **Important**
>
> The AWS account that owns the IAM role must have permissions for the actions that it grants to the IAM role.

For example, suppose that the source bucket contains objects owned by another AWS account. The owner of the objects must explicitly grant the AWS account that owns the IAM role the required permissions through the objects' access control lists (ACLs). Otherwise, Amazon S3 can't access the objects, and replication of the objects fails. For information about ACL permissions, see Access control list (ACL) overview.
The permissions described here are related to the minimum replication configuration. If you choose to add optional replication configurations, you must grant additional permissions to Amazon S3:

- To replicate encrypted objects, you also need to grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see the section called "Replicating encrypted objects".
- To use Object Lock with replication, you must grant 2 additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The 2 additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see the section called "Using Object Lock with S3 Replication".

(Optional) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts

When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also add a bucket policy to grant the owner of the source bucket permissions to perform replication actions, as shown in the following example. In this example policy, *amzn-s3-demo-destination-bucket* is the destination bucket.

You can also use the Amazon S3 console to automatically generate this bucket policy for you. For more information, see Enable receiving replicated objects from a source bucket.

Note

The ARN format of the role might appear different. If the role was created by using the console, the ARN format is `arn:aws:iam::`*account-ID*`:role/service-role/`*role-name*. If the role was created by using the AWS CLI, the ARN format is `arn:aws:iam::`*account-ID*`:role/`*role-name*. For more information, see IAM roles in the *IAM User Guide*.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "PolicyForDestinationBucket",
    "Statement": [
        {
            "Sid": "Permissions on objects",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/service-role/source-
account-IAM-role"
            },
            "Action": [
                "s3:ReplicateDelete",
                "s3:ReplicateObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
        },
        {
            "Sid": "Permissions on bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/service-role/source-
account-IAM-role"
            },
            "Action": [
                "s3:List*",
                "s3:GetBucketVersioning",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
        }
    ]
}
```

For an example, see Configuring replication for buckets in different accounts.

If objects in the source bucket are tagged, note the following:

- If the source bucket owner grants Amazon S3 permission for the `s3:GetObjectVersionTagging` and `s3:ReplicateTags` actions to replicate object tags (through the IAM role), Amazon S3 replicates the tags along with the objects. For information about the IAM role, see Step 2: Creating an IAM role for Amazon S3 to assume.
- If the owner of the destination bucket doesn't want to replicate the tags, they can add the following statement to the destination bucket policy to explicitly deny permission for the `s3:ReplicateTags` action. In this policy, *amzn-s3-demo-destination-bucket* is the destination bucket.

```
...
   "Statement":[
      {
         "Effect":"Deny",
         "Principal":{
            "AWS":"arn:aws:iam::source-bucket-account-id:role/service-role/source-account-IAM-role"
         },
         "Action":"s3:ReplicateTags",
         "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      }
   ]
...
```

- Similarly, if the source bucket owner grants Amazon S3 permission for the `s3:GetObjectVersionAnnotationForReplication` action to replicate annotations (through the IAM role), Amazon S3 replicates the annotations along with the objects. For information about the IAM role, see Step 2: Creating an IAM role for Amazon S3 to assume.

  If the owner of the destination bucket doesn't want to replicate the annotations, they can add the following statement to the destination bucket policy to explicitly deny permission for the `s3:ReplicateObjectAnnotation` action. In this policy, *amzn-s3-demo-destination-bucket* is the destination bucket.

```
...
   "Statement":[
      {
         "Effect":"Deny",
         "Principal":{
            "AWS":"arn:aws:iam::source-bucket-account-id:role/service-role/source-account-IAM-role"
```

```
            },
            "Action":"s3:ReplicateObjectAnnotation",
            "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
        }
    ]
...
```

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see the section called "Replicating encrypted objects".
- To use Object Lock with replication, you must grant 2 additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The 2 additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see the section called "Using Object Lock with S3 Replication".

Enable receiving replicated objects from a source bucket

Instead of manually adding the preceding policy to your destination bucket, you can quickly generate the policies needed to enable receiving replicated objects from a source bucket through the Amazon S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to use as a destination bucket.
4. Choose the **Management** tab, and scroll down to **Replication rules**.
5. For **Actions**, choose **Receive replicated objects**.

   Follow the prompts and enter the AWS account ID of the source bucket account, and then choose **Generate policies**. The console generates an Amazon S3 bucket policy and a KMS key policy.

6. To add this policy to your existing bucket policy, either choose **Apply settings** or choose **Copy** to manually copy the changes.
7. (Optional) Copy the AWS KMS policy to your desired KMS key policy in the AWS Key Management Service console.

(Optional) Step 4: Granting permissions to change replica ownership

When different AWS accounts own the source and destination buckets, you can tell Amazon S3 to change the ownership of the replica to the AWS account that owns the destination bucket. To override the ownership of replicas, you must either grant some additional permissions or adjust the S3 Object Ownership settings for the destination bucket. For more information about owner override, see Changing the replica owner.

Examples for configuring live replication

The following examples provide step-by-step walkthroughs that show how to configure live replication for common use cases.

> **Note**
>
> Live replication refers to Same-Region Replication (SRR) and Cross-Region Replication (CRR). Live replication doesn't replicate any objects that existed in the bucket before you set up replication. To replicate objects that existed before you set up replication, use on-demand replication. To sync buckets and replicate existing objects on demand, see Replicating existing objects.

These examples demonstrate how to create a replication configuration by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDKs (AWS SDK for Java and AWS SDK for .NET examples are shown).

For information about installing and configuring the AWS CLI, see the following topics in the *AWS Command Line Interface User Guide*:

- Get started with the AWS CLI
- Configure the AWS CLI – You must set up at least one profile. If you are exploring cross-account scenarios, set up two profiles.

For information about the AWS SDKs, see AWS SDK for Java and AWS SDK for .NET.

> **Tip**
>
> For a step-by-step tutorial that demonstrates how to use live replication to replicate data, see Tutorial: Replicating data within and between AWS Regions using S3 Replication.

Topics

- Configuring replication for buckets in the same account
- Configuring replication for buckets in different accounts
- Meeting compliance requirements with S3 Replication Time Control
- Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C)
- Replicating metadata changes with replica modification sync
- Replicating delete markers between buckets
- Replicating annotations

Configuring replication for buckets in the same account

Live replication is the automatic, asynchronous copying of objects across general purpose buckets in the same or different AWS Regions. Live replication copies newly created objects and object updates from a source bucket to a destination bucket or buckets. For more information, see Replicating objects within and across Regions.

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

In this example, you set up live replication for source and destination buckets that are owned by the same AWS account. Examples are provided for using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDK for Java and AWS SDK for .NET.

Prerequisites

Before you use the following procedures, make sure that you've set up the necessary permissions for replication, depending on whether the source and destination buckets are owned by the same or different accounts. For more information, see the section called "Setting up permissions".

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see the section called "Replicating encrypted objects".
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see the section called "Using Object Lock with S3 Replication".

Using the S3 console

To configure a replication rule when the destination bucket is in the same AWS account as the source bucket, follow these steps.

If the destination bucket is in a different account from the source bucket, you must add a bucket policy to the destination bucket to grant the owner of the source bucket account permission to replicate objects in the destination bucket. For more information, see (Optional) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want.

4. Choose the **Management** tab, scroll down to **Replication rules**, and then choose **Create replication rule**.

5. In the **Replication rule configuration** section, under **Replication rule name**, enter a name for your rule to help identify the rule later. The name is required and must be unique within the bucket.

6. Under **Status**, **Enabled** is selected by default. An enabled rule starts to work as soon as you save it. If you want to enable the rule later, choose **Disabled**.

7. If the bucket has existing replication rules, you are instructed to set a priority for the rule. You must set a priority for the rule to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see Replication configuration file elements.

8. Under **Source bucket**, you have the following options for setting the replication source:

   - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
   - To replicate all objects that have the same prefix, choose **Limit the scope of this rule using one or more filters**. This limits replication to all objects that have names that begin with the prefix that you specify (for example `pictures`). Enter a prefix in the **Prefix** box.

     > **Note**
     >
     > If you enter a prefix that is the name of a folder, you must use **/** (forward slash) as the last character (for example, `pictures/`).

   - To replicate all objects with one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. Repeat the procedure to add another tag. You can combine a prefix and tags. For more information about object tags, see Tagging your objects.

   The new replication configuration XML schema supports prefix and tag filtering and the prioritization of rules. For more information about the new schema, see Backward compatibility considerations. For more information about the XML used with the Amazon S3 API that works behind the user interface, see Replication configuration file elements. The new schema is described as *replication configuration XML V2*.

9. Under **Destination**, choose the bucket where you want Amazon S3 to replicate objects.

> **Note**
>
> The number of destination buckets is limited to the number of AWS Regions in a given partition. A partition is a grouping of Regions. AWS currently has three partitions: `aws` (Standard Regions), `aws-cn` (China Regions), and `aws-us-gov` (AWS GovCloud (US) Regions). To request an increase in your destination bucket quota, you can use service quotas.

- To replicate to a bucket or buckets in your account, choose **Choose a bucket in this account**, and enter or browse for the destination bucket names.
- To replicate to a bucket or buckets in a different AWS account, choose **Specify a bucket in another account**, and enter the destination bucket account ID and bucket name.

  If the destination is in a different account from the source bucket, you must add a bucket policy to the destination buckets to grant the owner of the source bucket account permission to replicate objects. For more information, see (Optional) Step 3: Granting permissions when the source and destination buckets are owned by different AWS accounts.

  Optionally, if you want to help standardize ownership of new objects in the destination bucket, choose **Change object ownership to the destination bucket owner**. For more information about this option, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Note**
>
> If versioning is not enabled on the destination bucket, you get a warning that contains an **Enable versioning** button. Choose this button to enable versioning on the bucket.

10. Set up an AWS Identity and Access Management (IAM) role that Amazon S3 can assume to replicate objects on your behalf.

    To set up an IAM role, in the **IAM role** section, select one of the following from the **IAM role** dropdown list:

- We highly recommend that you choose **Create new role** to have Amazon S3 create a new IAM role for you. When you save the rule, a new policy is generated for the IAM role that matches the source and destination buckets that you choose.
- You can choose to use an existing IAM role. If you do, you must choose a role that grants Amazon S3 the necessary permissions for replication. Replication fails if this role does not grant Amazon S3 sufficient permissions to follow your replication rule.

> **Important**
>
> When you add a replication rule to a bucket, you must have the `iam:PassRole` permission to be able to pass the IAM role that grants Amazon S3 replication permissions. For more information, see Granting a user permissions to pass a role to an AWS service in the *IAM User Guide*.

11. To replicate objects in the source bucket that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), under **Encryption**, select **Replicate objects encrypted with AWS KMS**. Under **AWS KMS keys for encrypting destination objects** are the source keys that you allow replication to use. All source KMS keys are included by default. To narrow the KMS key selection, you can choose an alias or key ID.

    Objects encrypted by AWS KMS keys that you do not select are not replicated. A KMS key or a group of KMS keys is chosen for you, but you can choose the KMS keys if you want. For information about using AWS KMS with replication, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).

    > **Important**
    >
    > When you replicate objects that are encrypted with AWS KMS, the AWS KMS request rate doubles in the source Region and increases in the destination Region by the same amount. These increased call rates to AWS KMS are due to the way that data is re-encrypted by using the KMS key that you define for the replication destination Region. AWS KMS has a request rate quota that is per calling account per Region. For information about the quota defaults, see AWS KMS Quotas - Requests per Second: Varies in the *AWS Key Management Service Developer Guide*.
    > If your current Amazon S3 PUT object request rate during replication is more than half the default AWS KMS rate limit for your account, we recommend that you request an

increase to your AWS KMS request rate quota. To request an increase, create a case in the Support Center at Contact Us. For example, suppose that your current PUT object request rate is 1,000 requests per second and you use AWS KMS to encrypt your objects. In this case, we recommend that you ask Support to increase your AWS KMS rate limit to 2,500 requests per second, in both your source and destination Regions (if different), to ensure that there is no throttling by AWS KMS.
To see your PUT object request rate in the source bucket, view `PutRequests` in the Amazon CloudWatch request metrics for Amazon S3. For information about viewing CloudWatch metrics, see Using the S3 console.

If you chose to replicate objects encrypted with AWS KMS, do the following:

- Under **AWS KMS key for encrypting destination objects** , specify your KMS key in one of the following ways:
  - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

    Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.
  - To enter the KMS key Amazon Resource Name (ARN), choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears. This encrypts the replicas in the destination bucket. You can find the ARN for your KMS key in the IAM Console, under **Encryption keys**.
  - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

    For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*.

    Important

    You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console lists only 100 KMS keys per Region. If you have more than 100 KMS keys in the same

Region, you can see only the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN.
When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see Identifying symmetric and asymmetric KMS keys in the *AWS Key Management Service Developer Guide*.

For more information about creating an AWS KMS key, see Creating keys in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see Using server-side encryption with AWS KMS keys (SSE-KMS).

12. Under **Destination storage class**, if you want to replicate your data into a specific storage class in the destination, choose **Change the storage class for the replicated objects**. Then choose the storage class that you want to use for the replicated objects in the destination. If you don't choose this option, the storage class for replicated objects is the same class as the original objects.
13. You have the following additional options while setting the **Additional replication options**:

    - If you want to enable S3 Replication Time Control (S3 RTC) in your replication configuration, select **Replication Time Control (RTC)**. For more information about this option, see Meeting compliance requirements with S3 Replication Time Control.
    - If you want to enable S3 Replication metrics in your replication configuration, select **Replication metrics and events**. For more information, see Monitoring replication with metrics, event notifications, and statuses.
    - If you want to enable delete marker replication in your replication configuration, select **Delete marker replication**. For more information, see Replicating delete markers between buckets.
    - If you want to enable Amazon S3 replica modification sync in your replication configuration, select **Replica modification sync**. For more information, see Replicating metadata changes with replica modification sync.

> **Note**
>
> When you use S3 RTC or S3 Replication metrics, additional fees apply.

14. To finish, choose **Save**.
15. After you save your rule, you can edit, enable, disable, or delete your rule by selecting your rule and choosing **Edit rule**.

Using the AWS CLI

To use the AWS CLI to set up replication when the source and destination buckets are owned by the same AWS account, you do the following:

- Create source and destination buckets.
- Enable versioning on the buckets.
- Create an AWS Identity and Access Management (IAM) role that gives Amazon S3 permission to replicate objects.
- Add the replication configuration to the source bucket.

To verify your setup, you test it.

To set up replication when the source and destination buckets are owned by the same AWS account

1. Set a credentials profile for the AWS CLI. This example uses the profile name `acctA`. For information about setting credential profiles and using named profiles, see Configuration and credential file settings in the *AWS Command Line Interface User Guide*.

   > **Important**
   >
   > The profile that you use for this example must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile that you use has the `iam:PassRole` permission. For more information, see Grant a user permissions to pass a role to an

AWS service in the *IAM User Guide*. If you use administrator credentials to create a named profile, you can perform all the tasks.

2. Create a source bucket and enable versioning on it by using the following AWS CLI commands. To use these commands, replace the *`user input placeholders`* with your own information.

   The following `create-bucket` command creates a source bucket named *`amzn-s3-demo-source-bucket`* in the US East (N. Virginia) (`us-east-1`) Region:

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

   The following `put-bucket-versioning` command enables S3 Versioning on the *`amzn-s3-demo-source-bucket`* bucket:

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a destination bucket and enable versioning on it by using the following AWS CLI commands. To use these commands, replace the *`user input placeholders`* with your own information.

   Note

   To set up a replication configuration when both source and destination buckets are in the same AWS account, you use the same profile for the source and destination buckets. This example uses `acctA`.
   To test a replication configuration when the buckets are owned by different AWS accounts, specify different profiles for each account. For example, use an `acctB` profile for the destination bucket.

The following `create-bucket` command creates a destination bucket named *amzn-s3-demo-destination-bucket* in the US West (Oregon) (`us-west-2`) Region:

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctA
```

The following `put-bucket-versioning` command enables S3 Versioning on the *amzn-s3-demo-destination-bucket* bucket:

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

4. Create an IAM role. You specify this role in the replication configuration that you add to the source bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

   - Create a role.
   - Attach a permissions policy to the role.

   a. Create the IAM role.

      i. Copy the following trust policy and save it to a file named `s3-role-trust-policy.json` in the current directory on your local computer. This policy grants the Amazon S3 service principal permissions to assume the role.

      JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
```

```
            "Service":"s3.amazonaws.com"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

ii. Run the following command to create a role.

```
$ aws iam create-role \
--role-name replicationRole \
--assume-role-policy-document file://s3-role-trust-policy.json  \
--profile acctA
```

b. Attach a permissions policy to the role.

i. Copy the following permissions policy and save it to a file named `s3-role-permissions-policy.json` in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:GetObjectVersionForReplication",
            "s3:GetObjectVersionAcl",
            "s3:GetObjectVersionTagging"
         ],
         "Resource":[
            "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
         ]
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:ListBucket",
            "s3:GetReplicationConfiguration"
         ],
```

```
            "Resource":[
               "arn:aws:s3:::amzn-s3-demo-source-bucket"
            ]
         },
         {
            "Effect":"Allow",
            "Action":[
               "s3:ReplicateObject",
               "s3:ReplicateDelete",
               "s3:ReplicateTags"
            ],
            "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
         }
      ]
}
```

> **Note**
>
> - If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see the section called "Replicating encrypted objects".
> - To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see the section called "Using Object Lock with S3 Replication".
> - To replicate object annotations, you must also grant `s3:GetObjectVersionAnnotationForReplication` on the source S3 bucket in the IAM role permissions policy. For more information, see the section called "Replicating metadata changes".

ii. Run the following command to create a policy and attach it to the role. Replace the *`user input placeholders`* with your own information.

```
$ aws iam put-role-policy \
--role-name replicationRole \
```

```
--policy-document file://s3-role-permissions-policy.json \
--policy-name replicationRolePolicy \
--profile acctA
```

5. Add a replication configuration to the source bucket.

   a. Although the Amazon S3 API requires that you specify the replication configuration as XML, the AWS CLI requires that you specify the replication configuration as JSON. Save the following JSON in a file called `replication.json` to the local directory on your computer.

```
{
  "Role": "IAM-role-ARN",
  "Rules": [
    {
      "Status": "Enabled",
      "Priority": 1,
      "DeleteMarkerReplication": { "Status": "Disabled" },
      "Filter" : { "Prefix": "Tax"},
      "Destination": {
        "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
      }
    }
  ]
}
```

   b. Update the JSON by replacing the values for the *amzn-s3-demo-destination-bucket* and *IAM-role-ARN* with your own information. Save the changes.

   c. Run the following `put-bucket-replication` command to add the replication configuration to your source bucket. Be sure to provide the source bucket name:

```
$ aws s3api put-bucket-replication \
--replication-configuration file://replication.json \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

   To retrieve the replication configuration, use the `get-bucket-replication` command:

```
$ aws s3api get-bucket-replication \
--bucket amzn-s3-demo-source-bucket \
```

```
--profile acctA
```

6. Test the setup in the Amazon S3 console, by doing the following steps:

   a. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   b. In the left navigation pane, choose **Buckets**. In the **General purpose buckets** list, choose the source bucket.

   c. In the source bucket, create a folder named *Tax*.

   d. Add sample objects to the *Tax* folder in the source bucket.

   > **Note**
   >
   > The amount of time that it takes for Amazon S3 to replicate an object depends on the size of the object. For information about how to see the status of replication, see Getting replication status information.

   In the destination bucket, verify the following:

   - That Amazon S3 replicated the objects.
   - That the objects are replicas. On the **Properties** tab for your objects, scroll down to the **Object management overview** section. Under **Management configurations**, see the value under **Replication status**. Make sure that this value is set to `REPLICA`.
   - That the replicas are owned by the source bucket account. You can verify the object ownership on the **Permissions** tab for your objects.

     If the source and destination buckets are owned by different accounts, you can add an optional configuration to tell Amazon S3 to change the replica ownership to the destination account. For an example, see How to change the replica owner.

Using the AWS SDKs

Use the following code examples to add a replication configuration to a bucket with the AWS SDK for Java and AWS SDK for .NET, respectively.

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see the section called "Replicating encrypted objects".
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see the section called "Using Object Lock with S3 Replication".

Java

To add a replication configuration to a bucket and then retrieve and verify the configuration using the AWS SDK for Java, you can use the S3Client to manage replication settings programmatically.

For examples of how to configure replication with the AWS SDK for Java, see Set replication configuration on a bucket in the *Amazon S3 API Reference*.

C#

The following AWS SDK for .NET code example adds a replication configuration to a bucket and then retrieves it. To use this code, provide the names for your buckets and the Amazon Resource Name (ARN) for your IAM role. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CrossRegionReplicationTest
    {
```

```
        private const string sourceBucket = "*** source bucket ***";
        // Bucket ARN example - arn:aws:s3:::destinationbucket
        private const string destinationBucketArn = "*** destination bucket ARN
***";
        private const string roleArn = "*** IAM Role ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint sourceBucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        public static void Main()
        {
            s3Client = new AmazonS3Client(sourceBucketRegion);
            EnableReplicationAsync().Wait();
        }
        static async Task EnableReplicationAsync()
        {
            try
            {
                ReplicationConfiguration replConfig = new ReplicationConfiguration
                {
                    Role = roleArn,
                    Rules =
                        {
                            new ReplicationRule
                            {
                                Prefix = "Tax",
                                Status = ReplicationRuleStatus.Enabled,
                                Destination = new ReplicationDestination
                                {
                                    BucketArn = destinationBucketArn
                                }
                            }
                        }
                };

                PutBucketReplicationRequest putRequest = new
PutBucketReplicationRequest
                {
                    BucketName = sourceBucket,
                    Configuration = replConfig
                };

                PutBucketReplicationResponse putResponse = await
s3Client.PutBucketReplicationAsync(putRequest);
```

```
                // Verify configuration by retrieving it.
                await RetrieveReplicationConfigurationAsync(s3Client);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
        private static async Task RetrieveReplicationConfigurationAsync(IAmazonS3
 client)
        {
            // Retrieve the configuration.
            GetBucketReplicationRequest getRequest = new GetBucketReplicationRequest
            {
                BucketName = sourceBucket
            };
            GetBucketReplicationResponse getResponse = await
 client.GetBucketReplicationAsync(getRequest);
            // Print.
            Console.WriteLine("Printing replication configuration information...");
            Console.WriteLine("Role ARN: {0}", getResponse.Configuration.Role);
            foreach (var rule in getResponse.Configuration.Rules)
            {
                Console.WriteLine("ID: {0}", rule.Id);
                Console.WriteLine("Prefix: {0}", rule.Prefix);
                Console.WriteLine("Status: {0}", rule.Status);
            }
        }
    }
}
```

Configuring replication for buckets in different accounts

Live replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. Live replication copies newly created objects and object updates from a

source bucket to a destination bucket or buckets. For more information, see Replicating objects within and across Regions.

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

Setting up live replication when the source and destination buckets are owned by different AWS accounts is similar to setting up replication when both buckets are owned by the same account. However, there are several differences when you're configuring replication in a cross-account scenario:

- The destination bucket owner must grant the source bucket owner permission to replicate objects in the destination bucket policy.
- If you're replicating objects that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) in a cross-account scenario, the owner of the KMS key must grant the source bucket owner permission to use the KMS key. For more information, see Granting additional permissions for cross-account scenarios.
- By default, replicated objects are owned by the source bucket owner. In a cross-account scenario, you might want to configure replication to change the ownership of the replicated objects to the owner of the destination bucket. For more information, see Changing the replica owner.

To configure replication when the source and destination buckets are owned by different AWS accounts

1. In this example, you create source and destination buckets in two different AWS accounts. You must have two credential profiles set for the AWS CLI. This example uses `acctA` and `acctB` for those profile names. For information about setting credential profiles and using named

profiles, see Configuration and credential file settings in the *AWS Command Line Interface User Guide*.

2. Follow the step-by-step instructions in Configuring replication for buckets in the same account with the following changes:

   - For all AWS CLI commands related to source bucket activities (such as creating the source bucket, enabling versioning, and creating the IAM role), use the `acctA` profile. Use the `acctB` profile to create the destination bucket.
   - Make sure that the permissions policy for the IAM role specifies the source and destination buckets that you created for this example.

3. In the console, add the following bucket policy on the destination bucket to allow the owner of the source bucket to replicate objects. For instructions, see Adding a bucket policy by using the Amazon S3 console. Be sure to edit the policy by providing the AWS account ID of the source bucket owner, the IAM role name, and the destination bucket name.

   Note

   To use the following example, replace the *`user input placeholders`* with your own information. Replace *`amzn-s3-demo-destination-bucket`* with your destination bucket name. Replace *`source-bucket-account-ID`*`:role/`*`source-account-IAM-role`* in the IAM Amazon Resource Name (ARN) with the IAM role that you're using for this replication configuration.
   The role path in the IAM ARN depends on how you created the role. If you created the role with the AWS CLI (as shown in Configuring replication for buckets in the same account), the path is `role/`*`role-name`*. If you created the role with the IAM console as a service role, the path includes `service-role/` (that is, `role/service-role/`*`role-name`*). For more information, see IAM ARNs in the *IAM User Guide*.

```
{
    "Version":"2012-10-17",
    "Id": "",
    "Statement": [
        {
            "Sid": "Set-permissions-for-objects",
            "Effect": "Allow",
            "Principal": {
```

```
                "AWS": "arn:aws:iam::source-bucket-account-ID:role/source-account-
IAM-role"
            },
            "Action": [
                "s3:ReplicateObject",
                "s3:ReplicateDelete"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
        },
        {
            "Sid": "Set-permissions-on-bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::source-bucket-account-ID:role/source-account-
IAM-role"
            },
            "Action": [
                "s3:GetBucketVersioning",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
        }
    ]
}
```

4. (Optional) If you're replicating objects that are encrypted with SSE-KMS, the owner of the KMS key must grant the source bucket owner permission to use the KMS key. For more information, see Granting additional permissions for cross-account scenarios.
5. (Optional) In replication, the owner of the source object owns the replica by default. When the source and destination buckets are owned by different AWS accounts, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets. This includes granting the `ObjectOwnerOverrideToBucketOwner` permission. For more information, see Changing the replica owner.

Changing the replica owner

In replication, the owner of the source object also owns the replica by default. However, when the source and destination buckets are owned by different AWS accounts, you might want to change the replica ownership. For example, you might want to change the ownership to restrict access to object replicas. In your replication configuration, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets.

To change the replica owner, you do the following:

- Add the *owner override* option to the replication configuration to tell Amazon S3 to change replica ownership.
- Grant Amazon S3 the `s3:ObjectOwnerOverrideToBucketOwner` permission to change replica ownership.
- Add the `s3:ObjectOwnerOverrideToBucketOwner` permission in the destination bucket policy to allow changing replica ownership. The `s3:ObjectOwnerOverrideToBucketOwner` permission allows the owner of the destination buckets to accept the ownership of object replicas.

For more information, see the section called "Considerations for the ownership override option" and Adding the owner override option to the replication configuration. For a working example with step-by-step instructions, see How to change the replica owner.

> **Important**
>
> Instead of using the owner override option, you can use the bucket owner enforced setting for Object Ownership. When you use replication and the source and destination buckets are owned by different AWS accounts, the bucket owner of the destination bucket can use the bucket owner enforced setting for Object Ownership to change replica ownership to the AWS account that owns the destination bucket. This setting disables object access control lists (ACLs).
>
> The bucket owner enforced setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the bucket owner enforced setting are owned by the destination bucket owner. For more information about Object Ownership, see Controlling ownership of objects and disabling ACLs for your bucket.

Considerations for the ownership override option

When you configure the ownership override option, the following considerations apply:

- By default, the owner of the source object also owns the replica. Amazon S3 replicates the object version and the ACL associated with it.

If you add the owner override option to your replication configuration, Amazon S3 replicates only the object version, not the ACL. In addition, Amazon S3 doesn't replicate subsequent changes to the source object ACL. Amazon S3 sets the ACL on the replica that grants full control to the destination bucket owner.

- When you update a replication configuration to enable or disable the owner override, the following behavior occurs:
  - If you add the owner override option to the replication configuration:

    When Amazon S3 replicates an object version, it discards the ACL that's associated with the source object. Instead, Amazon S3 sets the ACL on the replica, giving full control to the owner of the destination bucket. Amazon S3 doesn't replicate subsequent changes to the source object ACL. However, this ACL change doesn't apply to object versions that were replicated before you set the owner override option. ACL updates on source objects that were replicated before the owner override was set continue to be replicated (because the object and its replicas continue to have the same owner).
  - If you remove the owner override option from the replication configuration:

    Amazon S3 replicates new objects that appear in the source bucket and the associated ACLs to the destination buckets. For objects that were replicated before you removed the owner override, Amazon S3 doesn't replicate the ACLs because the object ownership change that Amazon S3 made remains in effect. That is, ACLs put on the object version that were replicated when the owner override was set continue to be not replicated.

Adding the owner override option to the replication configuration

> **Warning**
>
> Add the owner override option only when the source and destination buckets are owned by different AWS accounts. Amazon S3 doesn't check if the buckets are owned by the same or different accounts. If you add the owner override when both buckets are owned by same AWS account, Amazon S3 applies the owner override. This option grants full permissions to the owner of the destination bucket and doesn't replicate subsequent updates to the source objects' access control lists (ACLs). The replica owner can directly change the ACL associated with a replica with a `PutObjectAcl` request, but not through replication.

To specify the owner override option, add the following to each `Destination` element:

- The `AccessControlTranslation` element, which tells Amazon S3 to change replica ownership
- The `Account` element, which specifies the AWS account of the destination bucket owner

```
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    ...
    <Destination>
      ...
      <AccessControlTranslation>
           <Owner>Destination</Owner>
       </AccessControlTranslation>
      <Account>destination-bucket-owner-account-id</Account>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

The following example replication configuration tells Amazon S3 to replicate objects that have the *Tax* key prefix to the *amzn-s3-demo-destination-bucket* destination bucket and change ownership of the replicas. To use this example, replace the *user input placeholders* with your own information.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
   <Role>arn:aws:iam::account-id:role/role-name</Role>
   <Rule>
      <ID>Rule-1</ID>
      <Priority>1</Priority>
      <Status>Enabled</Status>
      <DeleteMarkerReplication>
         <Status>Disabled</Status>
      </DeleteMarkerReplication>
      <Filter>
         <Prefix>Tax</Prefix>
      </Filter>
      <Destination>
         <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
         <Account>destination-bucket-owner-account-id</Account>
         <AccessControlTranslation>
            <Owner>Destination</Owner>
```

```
        </AccessControlTranslation>
      </Destination>
   </Rule>
</ReplicationConfiguration>
```

Granting Amazon S3 permission to change replica ownership

Grant Amazon S3 permissions to change replica ownership by adding permission for the `s3:ObjectOwnerOverrideToBucketOwner` action in the permissions policy that's associated with the AWS Identity and Access Management (IAM) role. This role is the IAM role that you specified in the replication configuration that allows Amazon S3 to assume and replicate objects on your behalf. To use the following example, replace *amzn-s3-demo-destination-bucket* with the name of the destination bucket.

```
...
{
    "Effect":"Allow",
         "Action":[
       "s3:ObjectOwnerOverrideToBucketOwner"
    ],
    "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
...
```

Adding permission in the destination bucket policy to allow changing replica ownership

The owner of the destination bucket must grant the owner of the source bucket permission to change replica ownership. The owner of the destination bucket grants the owner of the source bucket permission for the `s3:ObjectOwnerOverrideToBucketOwner` action. This permission allows the destination bucket owner to accept ownership of the object replicas. The following example bucket policy statement shows how to do this. To use this example, replace the *user input placeholders* with your own information.

```
...
{
    "Sid":"1",
    "Effect":"Allow",
    "Principal":{"AWS":"source-bucket-account-id"},
    "Action":["s3:ObjectOwnerOverrideToBucketOwner"],
    "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
```

```
}
...
```

How to change the replica owner

When the source and destination buckets in a replication configuration are owned by different AWS accounts, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. The following examples show how to use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDKs to change replica ownership.

Using the S3 console

For step-by-step instructions, see Configuring replication for buckets in the same account. This topic provides instructions for setting up a replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

The following procedure shows how to change replica ownership by using the AWS CLI. In this procedure, you do the following:

- Create the source and destination buckets.
- Enable versioning on the buckets.
- Create an AWS Identity and Access Management (IAM) role that gives Amazon S3 permission to replicate objects.
- Add the replication configuration to the source bucket.
- In the replication configuration, you direct Amazon S3 to change the replica ownership.
- You test your replication configuration.

To change replica ownership when the source and destination buckets are owned by different AWS accounts (AWS CLI)

To use the example AWS CLI commands in this procedure, replace the *`user input placeholders`* with your own information.

1. In this example, you create the source and destination buckets in two different AWS accounts. To work with these two accounts, configure the AWS CLI with two named profiles. This

example uses profiles named *acctA* and *acctB*, respectively. For information about setting credential profiles and using named profiles, see Configuration and credential file settings in the *AWS Command Line Interface User Guide*.

> **Important**
>
> The profiles that you use for this procedure must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile that you use has the `iam:PassRole` permission. If you use administrator user credentials to create a named profile, then you can perform all of the tasks in this procedure. For more information, see Granting a user permissions to pass a role to an AWS service in the *IAM User Guide*.

2. Create the source bucket and enable versioning. This example creates a source bucket named *amzn-s3-demo-source-bucket* in the US East (N. Virginia) (`us-east-1`) Region.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a destination bucket and enable versioning. This example creates a destination bucket named *amzn-s3-demo-destination-bucket* in the US West (Oregon) (`us-west-2`) Region. Use an AWS account profile that's different from the one that you used for the source bucket.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctB
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
```

```
--versioning-configuration Status=Enabled \
--profile acctB
```

4. You must add permissions to your destination bucket policy to allow changing the replica ownership.

   a. Save the following policy to a file named *destination-bucket-policy*.json. Make sure to replace the *user input placeholders* with your own information.

      JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "destination_bucket_policy_sid",
            "Principal": {
                "AWS": "source-bucket-owner-123456789012"
            },
            "Action": [
                "s3:ReplicateObject",
                "s3:ReplicateDelete",
                "s3:ObjectOwnerOverrideToBucketOwner",
                "s3:ReplicateTags",
                "s3:GetObjectVersionTagging"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
            ]
        }
    ]
}
```

   b. Add the preceding policy to the destination bucket by using the following `put-bucket-policy` command:

```
aws s3api put-bucket-policy --region $ {destination-region} --bucket $ {amzn-s3-demo-destination-bucket} --policy file://destination_bucket_policy.json
```

5. Create an IAM role. You specify this role in the replication configuration that you add to the source bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

   - Create the role.
   - Attach a permissions policy to the role.

   a. Create the IAM role.

      i. Copy the following trust policy and save it to a file named *s3-role-trust-policy*.json in the current directory on your local computer. This policy grants Amazon S3 permissions to assume the role.

      JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Service":"s3.amazonaws.com"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

      ii. Run the following AWS CLI `create-role` command to create the IAM role:

```
$ aws iam create-role \
--role-name replicationRole \
--assume-role-policy-document file://s3-role-trust-policy.json  \
--profile acctA
```

      Make note of the Amazon Resource Name (ARN) of the IAM role that you created. You will need this ARN in a later step.

   b. Attach a permissions policy to the role.

i. Copy the following permissions policy and save it to a file named *s3-role-perm-pol-changeowner*.json in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions. In the following steps, you attach this policy to the IAM role that you created earlier.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "s3:GetObjectVersionForReplication",
            "s3:GetObjectVersionAcl"
         ],
         "Resource":[
            "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
         ]
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:ListBucket",
            "s3:GetReplicationConfiguration"
         ],
         "Resource":[
            "arn:aws:s3:::amzn-s3-demo-source-bucket"
         ]
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:ReplicateObject",
            "s3:ReplicateDelete",
            "s3:ObjectOwnerOverrideToBucketOwner",
            "s3:ReplicateTags",
            "s3:GetObjectVersionTagging"
         ],
         "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      }
```

```
    ]
}
```

ii. To attach the preceding permissions policy to the role, run the following `put-role-policy` command:

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-perm-pol-changeowner.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

6. Add a replication configuration to your source bucket.

a. The AWS CLI requires specifying the replication configuration as JSON. Save the following JSON in a file named *`replication`*`.json` in the current directory on your local computer. In the configuration, the `AccessControlTranslation` specifies the change in replica ownership from the source bucket owner to the destination bucket owner.

```
{
   "Role":"IAM-role-ARN",
   "Rules":[
      {
         "Status":"Enabled",
         "Priority":1,
         "DeleteMarkerReplication":{
            "Status":"Disabled"
         },
         "Filter":{
         },
         "Status":"Enabled",
         "Destination":{
            "Bucket":"arn:aws:s3:::amzn-s3-demo-destination-bucket",
            "Account":"destination-bucket-owner-account-id",
            "AccessControlTranslation":{
               "Owner":"Destination"
            }
         }
      }
   ]
}
```

b. Edit the JSON by providing values for the destination bucket name, the destination bucket owner account ID, and the *IAM-role-ARN*. Replace *IAM-role-ARN* with the ARN of the IAM role that you created earlier. Save the changes.

c. To add the replication configuration to the source bucket, run the following command:

```
$ aws s3api put-bucket-replication \
--replication-configuration file://replication.json \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

7. Test your replication configuration by checking replica ownership in the Amazon S3 console.

a. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

b. Add objects to the source bucket. Verify that the destination bucket contains the object replicas and that the ownership of the replicas has changed to the AWS account that owns the destination bucket.

Using the AWS SDKs

For a code example to add a replication configuration, see Using the AWS SDKs. You must modify the replication configuration appropriately. For conceptual information, see Changing the replica owner.

Meeting compliance requirements with S3 Replication Time Control

S3 Replication Time Control (S3 RTC) helps you meet compliance or business requirements for data replication and provides visibility into Amazon S3 replication times. S3 RTC replicates most objects that you upload to Amazon S3 in seconds, and 99.9 percent of those objects within 15 minutes.

By default, S3 RTC includes two ways to track the progress of replication:

- **S3 Replication metrics** – You can use S3 Replication metrics to monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination Region, and the total number of operations that failed replication. You can then monitor each dataset that you replicate separately. You can also enable S3 Replication metrics independently of S3 RTC. For more information, see the section called “Using S3 Replication metrics”.

Replication rules with S3 Replication Time Control (S3 RTC) enabled publish S3 Replication metrics. Replication metrics are available within 15 minutes of enabling S3 RTC. Replication metrics are available through the Amazon S3 console, the Amazon S3 API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), and Amazon CloudWatch. For more information about CloudWatch metrics, see Monitoring metrics with Amazon CloudWatch. For more information about viewing replication metrics through the Amazon S3 console, see Viewing replication metrics.

S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For information, see Amazon CloudWatch pricing.

- **Amazon S3 Event Notifications** – S3 RTC provides `OperationMissedThreshold` and `OperationReplicatedAfterThreshold` events that notify the bucket owner if object replication exceeds or occurs after the 15-minute threshold. With S3 RTC, Amazon S3 Event Notifications can notify you in the rare instance when objects don't replicate within 15 minutes and when those objects replicate after the 15-minute threshold.

  Replication events are available within 15 minutes of enabling S3 RTC. Amazon S3 Event Notifications are available through Amazon SQS, Amazon SNS, or AWS Lambda. For more information, see the section called “Receiving replication failure events”.

Best practices and guidelines for S3 RTC

When replicating data in Amazon S3 with S3 Replication Time Control (S3 RTC) enabled, follow these best practice guidelines to optimize replication performance for your workloads.

Topics

- Amazon S3 Replication and request rate performance guidelines
- Estimating your replication request rates
- Exceeding S3 RTC data transfer rate quotas
- AWS KMS encrypted object replication request rates

Amazon S3 Replication and request rate performance guidelines

When uploading and retrieving storage from Amazon S3, your applications can achieve thousands of transactions per second in request performance. For example, an application can achieve at least

3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix in an S3 bucket, including the requests that S3 Replication makes on your behalf. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by parallelizing reads. For example, if you create 10 prefixes in an S3 bucket to parallelize reads, you can scale your read performance to 55,000 read requests per second.

Amazon S3 automatically scales in response to sustained request rates above these guidelines, or sustained request rates concurrent with LIST requests. While Amazon S3 is internally optimizing for the new request rate, you might receive HTTP 503 request responses temporarily until the optimization is complete. This behavior might occur with increases in request per second rates, or when you first enable S3 RTC. During these periods, your replication latency might increase. The S3 RTC service level agreement (SLA) doesn't apply to time periods when Amazon S3 performance guidelines on requests per second are exceeded.

The S3 RTC SLA also doesn't apply during time periods where your replication data transfer rate exceeds the default 1 gigabit per second (Gbps) quota. If you expect your replication transfer rate to exceed 1 Gbps, you can contact AWS Support Center or use Service Quotas to request an increase in your replication transfer rate quota.

Estimating your replication request rates

Your total request rate including the requests that Amazon S3 replication makes on your behalf must be within the Amazon S3 request rate guidelines for both the replication source and destination buckets. For each object replicated, Amazon S3 replication makes up to five GET/HEAD requests and one PUT request to the source bucket, and one PUT request to each destination bucket.

For example, if you expect to replicate 100 objects per second, Amazon S3 replication might perform an additional 100 PUT requests on your behalf for a total of 200 PUT requests per second to the source S3 bucket. Amazon S3 replication also might perform up to 500 GET/HEAD requests (5 GET/HEAD requests for each object that's replicated.)

> **Note**
>
> You incur costs for only one PUT request per object replicated. For more information, see the pricing information in the Amazon S3 FAQs about replication.

Exceeding S3 RTC data transfer rate quotas

If you expect your S3 RTC data transfer rate to exceed the default 1 Gbps quota, contact AWS Support Center or use Service Quotas to request an increase in your replication transfer rate quota. When calculating your transfer rate, include annotation data because annotation bytes count toward the S3 RTC data transfer rate quota.

AWS KMS encrypted object replication request rates

When you replicate objects that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), AWS KMS requests per second quotas apply. AWS KMS might reject an otherwise valid request because your request rate exceeds the quota for the number of requests per second. When a request is throttled, AWS KMS returns a `ThrottlingException` error. The AWS KMS request rate quota applies to requests that you make directly and to requests made by Amazon S3 replication on your behalf.

For example, if you expect to replicate 1,000 objects per second, you can subtract 2,000 requests from your AWS KMS request rate quota. The resulting request rate per second is available for your AWS KMS workloads excluding replication. You can use AWS KMS request metrics in Amazon CloudWatch to monitor the total AWS KMS request rate on your AWS account.

To request an increase to your AWS KMS requests per second quota, contact AWS Support Center or use Service Quotas.

Enabling S3 Replication Time Control

You can start using S3 Replication Time Control (S3 RTC) with a new or existing replication rule. You can choose to apply your replication rule to an entire bucket, or to objects with a specific prefix or tag. When you enable S3 RTC, S3 Replication metrics are also enabled on your replication rule.

You can configure S3 RTC by using the Amazon S3 console, the Amazon S3 API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI).

Using the S3 console

For step-by-step instructions, see Configuring replication for buckets in the same account. This topic provides instructions for enabling S3 RTC in your replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To use the AWS CLI to replicate objects with S3 RTC enabled, you create buckets, enable versioning on the buckets, create an IAM role that gives Amazon S3 permission to replicate objects, and add the replication configuration to the source bucket. The replication configuration must have S3 RTC enabled, as shown in the following example.

For step-by-step instructions for setting up your replication configuration by using the AWS CLI, see Configuring replication for buckets in the same account.

The following example replication configuration enables and sets the `ReplicationTime` and `EventThreshold` values for a replication rule. Enabling and setting these values enables S3 RTC on the rule.

```
{
    "Rules": [
        {
            "Status": "Enabled",
            "Filter": {
                "Prefix": "Tax"
            },
            "DeleteMarkerReplication": {
                "Status": "Disabled"
            },
            "Destination": {
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",
                "Metrics": {
                    "Status": "Enabled",
                    "EventThreshold": {
                        "Minutes": 15
                    }
                },
                "ReplicationTime": {
                    "Status": "Enabled",
                    "Time": {
                        "Minutes": 15
                    }
                }
            },
            "Priority": 1
        }
    ],
    "Role": "IAM-Role-ARN"
```

```
}
```

> **Important**
>
> `Metrics:EventThreshold:Minutes` and `ReplicationTime:Time:Minutes` can only have 15 as a valid value.

Using the AWS SDK for Java

The following Java example adds replication configuration with S3 Replication Time Control (S3 RTC) enabled.

```
import software.amazon.awssdk.auth.credentials.AwsBasicCredentials;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.model.DeleteMarkerReplication;
import software.amazon.awssdk.services.s3.model.Destination;
import software.amazon.awssdk.services.s3.model.Metrics;
import software.amazon.awssdk.services.s3.model.MetricsStatus;
import software.amazon.awssdk.services.s3.model.PutBucketReplicationRequest;
import software.amazon.awssdk.services.s3.model.ReplicationConfiguration;
import software.amazon.awssdk.services.s3.model.ReplicationRule;
import software.amazon.awssdk.services.s3.model.ReplicationRuleFilter;
import software.amazon.awssdk.services.s3.model.ReplicationTime;
import software.amazon.awssdk.services.s3.model.ReplicationTimeStatus;
import software.amazon.awssdk.services.s3.model.ReplicationTimeValue;

public class Main {

  public static void main(String[] args) {
    S3Client s3 = S3Client.builder()
      .region(Region.US_EAST_1)
      .credentialsProvider(() -> AwsBasicCredentials.create(
          "AWS_ACCESS_KEY_ID",
          "AWS_SECRET_ACCESS_KEY")
      )
      .build();

    ReplicationConfiguration replicationConfig = ReplicationConfiguration
      .builder()
      .rules(
          ReplicationRule
```

```
            .builder()
            .status("Enabled")
            .priority(1)
            .deleteMarkerReplication(
                DeleteMarkerReplication
                    .builder()
                    .status("Disabled")
                    .build()
            )
            .destination(
                Destination
                    .builder()
                    .bucket("destination_bucket_arn")
                    .replicationTime(
                        ReplicationTime.builder().time(
                            ReplicationTimeValue.builder().minutes(15).build()
                        ).status(
                            ReplicationTimeStatus.ENABLED
                        ).build()
                    )
                    .metrics(
                        Metrics.builder().eventThreshold(
                            ReplicationTimeValue.builder().minutes(15).build()
                        ).status(
                            MetricsStatus.ENABLED
                        ).build()
                    )
                    .build()
            )
            .filter(
                ReplicationRuleFilter
                    .builder()
                    .prefix("testtest")
                    .build()
            )
        .build())
        .role("role_arn")
        .build();

    // Put replication configuration
    PutBucketReplicationRequest putBucketReplicationRequest =
PutBucketReplicationRequest
      .builder()
      .bucket("source_bucket")
```

```
      .replicationConfiguration(replicationConfig)
      .build();

    s3.putBucketReplication(putBucketReplicationRequest);
  }
}
```

Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C)

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

There are some special considerations when you're replicating objects that have been encrypted by using server-side encryption. Amazon S3 supports the following types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information about server-side encryption, see the section called “Server-side encryption”.

This topic explains the permissions that you need to direct Amazon S3 to replicate objects that have been encrypted by using server-side encryption. This topic also provides additional configuration elements that you can add and example AWS Identity and Access Management (IAM) policies that grant the necessary permissions for replicating encrypted objects.

For an example with step-by-step instructions, see Enabling replication for encrypted objects. For information about creating a replication configuration, see Replicating objects within and across Regions.

> **Note**
>
> You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see Using multi-Region keys in the *AWS Key Management Service Developer Guide*.

Topics

- How default bucket encryption affects replication
- Replicating objects encrypted with SSE-C
- Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS
- Enabling replication for encrypted objects

How default bucket encryption affects replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.
- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

Replicating objects encrypted with SSE-C

By using server-side encryption with customer-provided keys (SSE-C), you can manage your own proprietary encryption keys. With SSE-C, you manage the keys while Amazon S3 manages the

encryption and decryption process. You must provide an encryption key as part of your request, but you don't need to write any code to perform object encryption or decryption. When you upload an object, Amazon S3 encrypts the object by using the key that you provided. Amazon S3 then purges that key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. For more information, see the section called "Customer-provided encryption keys (SSE-C)".

S3 Replication supports objects that are encrypted with SSE-C. You can configure SSE-C object replication in the Amazon S3 console or with the AWS SDKs in the same way that you configure replication for unencrypted objects. There aren't additional SSE-C permissions beyond what are currently required for replication.

S3 Replication automatically replicates newly uploaded SSE-C encrypted objects if they are eligible, as specified in your S3 Replication configuration. To replicate existing objects in your buckets, use S3 Batch Replication. For more information about replicating objects, see the section called "Setting up live replication" and the section called "Replicating existing objects".

There are no additional charges for replicating SSE-C objects. For details about replication pricing, see Amazon S3 pricing.

Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS

By default, Amazon S3 doesn't replicate objects that are encrypted with SSE-KMS or DSSE-KMS. This section explains the additional configuration elements that you can add to direct Amazon S3 to replicate these objects.

For an example with step-by-step instructions, see Enabling replication for encrypted objects. For information about creating a replication configuration, see Replicating objects within and across Regions.

Specifying additional information in the replication configuration

In the replication configuration, you do the following:

- In the `Destination` element in your replication configuration, add the ID of the symmetric AWS KMS customer managed key that you want Amazon S3 to use to encrypt object replicas, as shown in the following example replication configuration.
- Explicitly opt in by enabling replication of objects encrypted by using KMS keys (SSE-KMS or DSSE-KMS). To opt in, add the `SourceSelectionCriteria` element, as shown in the following example replication configuration.

```
<ReplicationConfiguration>
   <Rule>
      ...
      <SourceSelectionCriteria>
         <SseKmsEncryptedObjects>
           <Status>Enabled</Status>
         </SseKmsEncryptedObjects>
      </SourceSelectionCriteria>

      <Destination>
          ...
          <EncryptionConfiguration>
             <ReplicaKmsKeyID>AWS KMS key ARN or Key Alias ARN that's in the same AWS
 Region as the destination bucket.</ReplicaKmsKeyID>
          </EncryptionConfiguration>
       </Destination>
      ...
   </Rule>
</ReplicationConfiguration>
```

Important

- The KMS key must have been created in the same AWS Region as the destination bucket.
- The KMS key *must* be valid. The `PutBucketReplication` API operation doesn't check the validity of KMS keys. If you use a KMS key that isn't valid, you will receive the HTTP `200 OK` status code in response, but replication fails.

The following example shows a replication configuration that includes optional configuration elements. This replication configuration has one rule. The rule applies to objects with the *Tax* key prefix. Amazon S3 uses the specified AWS KMS key ID to encrypt these object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration>
   <Role>arn:aws:iam::account-id:role/role-name</Role>
   <Rule>
      <ID>Rule-1</ID>
      <Priority>1</Priority>
      <Status>Enabled</Status>
      <DeleteMarkerReplication>
```

```
         <Status>Disabled</Status>
      </DeleteMarkerReplication>
      <Filter>
         <Prefix>Tax</Prefix>
      </Filter>
      <Destination>
         <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
         <EncryptionConfiguration>
            <ReplicaKmsKeyID>AWS KMS key ARN or Key Alias ARN that's in the same AWS
 Region as the destination bucket.</ReplicaKmsKeyID>
         </EncryptionConfiguration>
      </Destination>
      <SourceSelectionCriteria>
         <SseKmsEncryptedObjects>
            <Status>Enabled</Status>
         </SseKmsEncryptedObjects>
      </SourceSelectionCriteria>
   </Rule>
</ReplicationConfiguration>
```

Granting additional permissions for the IAM role

To replicate objects that are encrypted at rest by using SSE-S3, SSE-KMS, or DSSE-KMS, grant the following additional permissions to the AWS Identity and Access Management (IAM) role that you specify in the replication configuration. You grant these permissions by updating the permissions policy that's associated with the IAM role.

- **`s3:GetObjectVersionForReplication` action for source objects** – This action allows Amazon S3 to replicate both unencrypted objects and objects created with server-side encryption by using SSE-S3, SSE-KMS, or DSSE-KMS.

  > **Note**
  >
  > We recommend that you use the `s3:GetObjectVersionForReplication` action instead of the `s3:GetObjectVersion` action because `s3:GetObjectVersionForReplication` provides Amazon S3 with only the minimum permissions necessary for replication. In addition, the `s3:GetObjectVersion` action allows replication of unencrypted and SSE-S3-encrypted objects, but not of objects that are encrypted by using KMS keys (SSE-KMS or DSSE-KMS).

- **`kms:Decrypt` and `kms:Encrypt` AWS KMS actions for the KMS keys**

- You must grant `kms:Decrypt` permissions for the AWS KMS key that protects the source object.
- You must grant `kms:Encrypt` permissions for the AWS KMS key that will protect the object replica.

- **`kms:GenerateDataKey` action for replicating plaintext objects** – If you're replicating plaintext objects to a bucket with SSE-KMS or DSSE-KMS encryption enabled by default, you must include the `kms:GenerateDataKey` permission for the destination encryption context and the KMS key in the IAM policy.

> **Important**
>
> If you use S3 Batch Replication to replicate datasets cross region and your objects previously had their server-side encryption type updated from SSE-S3 to SSE-KMS, you may need additional permissions. On the source region bucket, you must have `kms:decrypt` permissions. Then, you will need the `kms:decrypt` and `kms:encrypt` permissions for the bucket in the destination region.

We recommend that you restrict these permissions only to the destination buckets and objects by using AWS KMS condition keys. The AWS account that owns the IAM role must have permissions for the `kms:Encrypt` and `kms:Decrypt` actions for the KMS keys that are listed in the policy. If the KMS keys are owned by another AWS account, the owner of the KMS keys must grant these permissions to the AWS account that owns the IAM role. For more information about managing access to these KMS keys, see Using IAM policies with AWS KMS in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys and replication

To use replication with an S3 Bucket Key, the AWS KMS key policy for the KMS key that's used to encrypt the object replica must include the `kms:Decrypt` permission for the calling principal. The call to `kms:Decrypt` verifies the integrity of the S3 Bucket Key before using it. For more information, see Using an S3 Bucket Key with replication.

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN (for example, `arn:aws:s3:::`*`bucket_ARN`*). You must update your IAM policies to use the bucket ARN for the encryption context:

```
"kms:EncryptionContext:aws:s3:arn": [
"arn:aws:s3:::bucket_ARN"
]
```

For more information, see Encryption context (`x-amz-server-side-encryption-context`) (in the "Using the REST API" section) and Changes to note before enabling an S3 Bucket Key.

Example policies: Using SSE-S3 and SSE-KMS with replication

The following example IAM policies show statements for using SSE-S3 and SSE-KMS with replication.

Example– Using SSE-KMS with separate destination buckets

The following example policy shows statements for using SSE-KMS with separate destination buckets.

Example– Replicating objects created with SSE-S3 and SSE-KMS

The following is a complete IAM policy that grants the necessary permissions to replicate unencrypted objects, objects created with SSE-S3, and objects created with SSE-KMS.

                     "arn:aws:s3:::amzn-s3-demo-source-bucket"
                  ]
               }
            },
            "Resource":[
              "arn:aws:kms:us-east-1:111122223333:key/key-id"
            ]
         },
         {
            "Action":[
               "kms:Encrypt"
            ],
            "Effect":"Allow",
            "Condition":{
               "StringLike":{
                  "kms:ViaService":"s3.us-east-1.amazonaws.com",
                  "kms:EncryptionContext:aws:s3:arn":[
                     "arn:aws:s3:::amzn-s3-demo-destination-bucket"
                  ]
               }
            },
            "Resource":[
               "arn:aws:kms:us-east-1:111122223333:key/key-id"
            ]
         }
      ]
   }
```

Granting additional permissions for cross-account scenarios

In a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, you can use a KMS key to encrypt object replicas. However, the KMS key owner must grant the source bucket owner permission to use the KMS key.

> **Note**
>
> If you need to replicate SSE-KMS data cross-account, then your replication rule must specify a customer managed key from AWS KMS for the destination account. AWS managed keys don't allow cross-account use, and therefore can't be used to perform cross-account replication.

To grant the source bucket owner permission to use the KMS key (AWS KMS console)

1. Sign in to the AWS Management Console and open the AWS KMS console at https://console.aws.amazon.com/kms.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**.
4. Choose the KMS key.
5. Under the **General configuration** section, choose the **Key policy** tab.
6. Scroll down to **Other AWS accounts**.
7. Choose **Add other AWS accounts**.

   The **Other AWS accounts** dialog box appears.
8. In the dialog box, choose **Add another AWS account**. For **arn:aws:iam::**, enter the source bucket account ID.
9. Choose **Save changes**.

To grant the source bucket owner permission to use the KMS key (AWS CLI)

- For information about the `put-key-policy` AWS Command Line Interface (AWS CLI) command, see put-key-policy in the *AWS CLI Command Reference*. For information about the underlying `PutKeyPolicy` API operation, see PutKeyPolicy in the AWS Key Management Service API Reference.

AWS KMS transaction quota considerations

When you add many new objects with AWS KMS encryption after enabling Cross-Region Replication (CRR), you might experience throttling (HTTP `503 Service Unavailable` errors). Throttling occurs when the number of AWS KMS transactions per second exceeds the current quota. For more information, see Quotas in the *AWS Key Management Service Developer Guide*.

To request a quota increase, use Service Quotas. For more information, see Requesting a quota increase. If Service Quotas isn't supported in your Region, open an AWS Support case.

Enabling replication for encrypted objects

By default, Amazon S3 doesn't replicate objects that are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). To replicate objects encrypted with SSE-KMS or DSS-KMS, you must modify the bucket replication configuration to tell Amazon S3 to replicate these objects. This example explains how to use the Amazon S3 console and the AWS Command Line Interface (AWS CLI) to change the bucket replication configuration to enable replicating encrypted objects.

Note

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN. You must update your IAM policies to use the bucket ARN for the encryption context. For more information, see S3 Bucket Keys and replication.

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see Using multi-Region keys in the *AWS Key Management Service Developer Guide*.

Using the S3 console

For step-by-step instructions, see Configuring replication for buckets in the same account. This topic provides instructions for setting a replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To replicate encrypted objects with the AWS CLI, you do the following:

- Create source and destination buckets and enable versioning on these buckets.
- Create an AWS Identity and Access Management (IAM) service role that gives Amazon S3 permission to replicate objects. The IAM role's permissions include the necessary permissions to replicate the encrypted objects.
- Add a replication configuration to the source bucket. The replication configuration provides information related to replicating objects that are encrypted by using KMS keys.
- Add encrypted objects to the source bucket.
- Test the setup to confirm that your encrypted objects are being replicated to the destination bucket.

The following procedures walk you through this process.

To replicate server-side encrypted objects (AWS CLI)

To use the examples in this procedure, replace the *`user input placeholders`* with your own information.

1. In this example, you create both the source (*`amzn-s3-demo-source-bucket`*) and destination (*`amzn-s3-demo-destination-bucket`*) buckets in the same AWS account. You also set a credentials profile for the AWS CLI. This example uses the profile name *`acctA`*.

   For information about setting credential profiles and using named profiles, see Configuration and credential file settings in the *AWS Command Line Interface User Guide*.
2. Use the following commands to create the *`amzn-s3-demo-source-bucket`* bucket and enable versioning on it. The following example commands create the *`amzn-s3-demo-source-bucket`* bucket in the US East (N. Virginia) (`us-east-1`) Region.

   ```
   aws s3api create-bucket \
   --bucket amzn-s3-demo-source-bucket \
   --region us-east-1 \
   --profile acctA
   ```

   ```
   aws s3api put-bucket-versioning \
   --bucket amzn-s3-demo-source-bucket \
   ```

```
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Use the following commands to create the *amzn-s3-demo-destination-bucket* bucket and enable versioning on it. The following example commands create the *amzn-s3-demo-destination-bucket* bucket in the US West (Oregon) (`us-west-2`) Region.

> **Note**
>
> To set up a replication configuration when both *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets are in the same AWS account, you use the same profile. This example uses *acctA*. To configure replication when the buckets are owned by different AWS accounts, you specify different profiles for each.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

4. Next, you create an IAM service role. You will specify this role in the replication configuration that you add to the *amzn-s3-demo-source-bucket* bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

   - Create a service role.
   - Attach a permissions policy to the role.

   a. To create an IAM service role, do the following:

      i. Copy the following trust policy and save it to a file called *s3-role-trust-policy-kmsobj*`.json` in the current directory on your local computer. This policy grants the

Amazon S3 service principal permissions to assume the role so that Amazon S3 can perform tasks on your behalf.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Service":"s3.amazonaws.com"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

ii. Use the following command to create the role:

```
$ aws iam create-role \
--role-name replicationRolekmsobj \
--assume-role-policy-document file://s3-role-trust-policy-kmsobj.json  \
--profile acctA
```

b. Next, you attach a permissions policy to the role. This policy grants permissions for various Amazon S3 bucket and object actions.

i. Copy the following permissions policy and save it to a file named *s3-role-permissions-policykmsobj*.json in the current directory on your local computer. You will create an IAM role and attach the policy to it later.

> **Important**
>
> In the permissions policy, you specify the AWS KMS key IDs that will be used for encryption of the *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets. You must create two separate KMS keys for the *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-*

bucket buckets. AWS KMS keys aren't shared outside the AWS Region in which they were created.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Action":[
            "s3:ListBucket",
            "s3:GetReplicationConfiguration",
            "s3:GetObjectVersionForReplication",
            "s3:GetObjectVersionAcl",
            "s3:GetObjectVersionTagging"
         ],
         "Effect":"Allow",
         "Resource":[
            "arn:aws:s3:::amzn-s3-demo-source-bucket",
            "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
         ]
      },
      {
         "Action":[
            "s3:ReplicateObject",
            "s3:ReplicateDelete",
            "s3:ReplicateTags"
         ],
         "Effect":"Allow",
         "Condition":{
            "StringLikeIfExists":{
               "s3:x-amz-server-side-encryption":[
                  "aws:kms",
                  "AES256",
                  "aws:kms:dsse"
               ],
               "s3:x-amz-server-side-encryption-aws-kms-key-id":[
                  "AWS KMS key IDs(in ARN format) to use for
 encrypting object replicas"
               ]
            }
```

```
            },
            "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
         },
         {
            "Action":[
               "kms:Decrypt"
            ],
            "Effect":"Allow",
            "Condition":{
               "StringLike":{
                  "kms:ViaService":"s3.us-east-1.amazonaws.com",
                  "kms:EncryptionContext:aws:s3:arn":[
                     "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
                  ]
               }
            },
            "Resource":[
               "arn:aws:kms:us-east-1:111122223333:key/key-id"
            ]
         },
         {
            "Action":[
               "kms:Encrypt"
            ],
            "Effect":"Allow",
            "Condition":{
               "StringLike":{
                  "kms:ViaService":"s3.us-west-2.amazonaws.com",
                  "kms:EncryptionContext:aws:s3:arn":[
                     "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
                  ]
               }
            },
            "Resource":[
               "arn:aws:kms:us-west-2:111122223333:key/key-id"
            ]
         }
      ]
}
```

ii. Create a policy and attach it to the role.

```
$ aws iam put-role-policy \
--role-name replicationRolekmsobj \
```

```
--policy-document file://s3-role-permissions-policykmsobj.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

5. Next, add the following replication configuration to the *amzn-s3-demo-source-bucket* bucket. It tells Amazon S3 to replicate objects with the *Tax/* prefix to the *amzn-s3-demo-destination-bucket* bucket.

> **Important**
>
> In the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if you have the `iam:PassRole` permission. The profile that you specify in the CLI command must have this permission. For more information, see Granting a user permissions to pass a role to an AWS service in the *IAM User Guide*.

```
<ReplicationConfiguration>
 <Role>IAM-Role-ARN</Role>
 <Rule>
   <Priority>1</Priority>
   <DeleteMarkerReplication>
      <Status>Disabled</Status>
   </DeleteMarkerReplication>
   <Filter>
      <Prefix>Tax</Prefix>
   </Filter>
   <Status>Enabled</Status>
   <SourceSelectionCriteria>
     <SseKmsEncryptedObjects>
       <Status>Enabled</Status>
     </SseKmsEncryptedObjects>
   </SourceSelectionCriteria>
   <Destination>
     <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
     <EncryptionConfiguration>
       <ReplicaKmsKeyID>AWS KMS key IDs to use for encrypting object replicas</
ReplicaKmsKeyID>
     </EncryptionConfiguration>
   </Destination>
  </Rule>
</ReplicationConfiguration>
```

To add a replication configuration to the *amzn-s3-demo-source-bucket* bucket, do the following:

a. The AWS CLI requires you to specify the replication configuration as JSON. Save the following JSON in a file (*replication*.json) in the current directory on your local computer.

```
{
   "Role":"IAM-Role-ARN",
   "Rules":[
      {
         "Status":"Enabled",
         "Priority":1,
         "DeleteMarkerReplication":{
            "Status":"Disabled"
         },
         "Filter":{
            "Prefix":"Tax"
         },
         "Destination":{
            "Bucket":"arn:aws:s3:::amzn-s3-demo-destination-bucket",
            "EncryptionConfiguration":{
               "ReplicaKmsKeyID":"AWS KMS key IDs (in ARN format) to use for
 encrypting object replicas"
            }
         },
         "SourceSelectionCriteria":{
            "SseKmsEncryptedObjects":{
               "Status":"Enabled"
            }
         }
      }
   ]
}
```

b. Edit the JSON to provide values for the *amzn-s3-demo-destination-bucket* bucket, *AWS KMS key IDs (in ARN format)*, and *IAM-role-ARN*. Save the changes.

c. Use the following command to add the replication configuration to your *amzn-s3-demo-source-bucket* bucket. Be sure to provide the *amzn-s3-demo-source-bucket* bucket name.

```
$ aws s3api put-bucket-replication \
--replication-configuration file://replication.json \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

6. Test the configuration to verify that encrypted objects are replicated. In the Amazon S3 console, do the following:

   a. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   b. In the *amzn-s3-demo-source-bucket* bucket, create a folder named *Tax*.

   c. Add sample objects to the folder. Be sure to choose the encryption option and specify your KMS key to encrypt the objects.

   d. Verify that the *amzn-s3-demo-destination-bucket* bucket contains the object replicas and that they are encrypted by using the KMS key that you specified in the configuration. For more information, see the section called "Getting replication status".

Using the AWS SDKs

For a code example that shows how to add a replication configuration, see Using the AWS SDKs. You must modify the replication configuration appropriately.

Replicating metadata changes with replica modification sync

Amazon S3 replica modification sync can help you keep object metadata such as tags, access control lists (ACLs), annotations, and Object Lock settings replicated between replicas and source objects. By default, Amazon S3 replicates metadata from the source objects to the replicas only. When replica modification sync is enabled, Amazon S3 replicates metadata changes made to the replica copies back to the source object, making the replication bidirectional (two-way replication).

Enabling replica modification sync

You can use Amazon S3 replica modification sync with new or existing replication rules. You can apply it to an entire bucket or to objects that have a specific prefix.

To enable replica modification sync by using the Amazon S3 console, see Examples for configuring live replication. This topic provides instructions for enabling replica modification sync in your

replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replica modification sync by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the bucket containing the replicas with `ReplicaModifications` enabled. To set up two-way replication, create a replication rule from the source bucket (*amzn-s3-demo-source-bucket*) to the bucket containing the replicas (*amzn-s3-demo-destination-bucket*). Then, create a second replication rule from the bucket containing the replicas (*amzn-s3-demo-destination-bucket*) to the source bucket (*amzn-s3-demo-source-bucket*). The source and destination buckets can be in the same or different AWS Regions.

> **Note**
>
> You must enable replica modification sync on both the source and destination buckets to replicate replica metadata changes like object access control lists (ACLs), object tags, object annotations, or Object Lock settings on the replicated objects. Like all replication rules, you can apply these rules to the entire bucket or to a subset of objects filtered by prefix or object tags.

In the following example configuration, Amazon S3 replicates metadata changes under the prefix *Tax* to the bucket *amzn-s3-demo-source-bucket*, which contains the source objects.

```
{
    "Rules": [
        {
            "Status": "Enabled",
            "Filter": {
                "Prefix": "Tax"
            },
            "SourceSelectionCriteria": {
                "ReplicaModifications":{
                    "Status": "Enabled"
                }
            },
            "Destination": {
                "Bucket": "arn:aws:s3:::amzn-s3-demo-source-bucket"
            },
            "Priority": 1
```

```
        }
    ],
    "Role": "IAM-Role-ARN"
}
```

For full instructions on creating replication rules by using the AWS CLI, see Configuring replication for buckets in the same account.

Replicating delete markers between buckets

By default, when S3 Replication is enabled and an object is deleted in the source bucket, Amazon S3 adds a delete marker in the source bucket only. This action helps protect data in the destination buckets from accidental or malicious deletions. If you have *delete marker replication* enabled, these markers are copied to the destination buckets, and Amazon S3 behaves as if the object was deleted in both the source and destination buckets. For more information about how delete markers work, see Working with delete markers.

Note

- Delete marker replication isn't supported for tag-based replication rules. Delete marker replication also doesn't adhere to the 15-minute service-level agreement (SLA) that's granted when you're using S3 Replication Time Control (S3 RTC).
- If you're not using the latest replication configuration XML version, delete operations affect replication differently. For more information, see How delete operations affect replication.
- If you enable delete marker replication and your source bucket has an S3 Lifecycle expiration rule, the delete markers added by the S3 Lifecycle expiration rule won't be replicated to the destination bucket.

Enabling delete marker replication

You can start using delete marker replication with a new or existing replication rule. You can apply delete marker replication to an entire bucket or to objects that have a specific prefix.

To enable delete marker replication by using the Amazon S3 console, see Using the S3 console. This topic provides instructions for enabling delete marker replication in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable delete marker replication by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with `DeleteMarkerReplication` enabled, as shown in the following example configuration.

In the following example replication configuration, delete markers are replicated to the destination bucket *amzn-s3-demo-destination-bucket* for objects under the prefix *Tax*.

```
{
    "Rules": [
        {
            "Status": "Enabled",
            "Filter": {
                "Prefix": "Tax"
            },
            "DeleteMarkerReplication": {
                "Status": "Enabled"
            },
            "Destination": {
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
            },
            "Priority": 1
        }
    ],
    "Role": "IAM-Role-ARN"
}
```

For full instructions on creating replication rules through the AWS CLI, see Configuring replication for buckets in the same account.

Replicating annotations

When you configure replication on a bucket, Amazon S3 replicates annotations automatically as part of live replication. Each annotation replicates independently as changes occur. To replicate annotations, the replication IAM role must include the `s3:GetObjectVersionAnnotationForReplication` permission on the source bucket.

The following example shows the source bucket statement in the IAM role permissions policy with the annotation replication permission included:

```
{
   "Effect": "Allow",
```

```
   "Action": [
      "s3:GetObjectVersionForReplication",
      "s3:GetObjectVersionAcl",
      "s3:GetObjectVersionTagging",
      "s3:GetObjectVersionAnnotationForReplication"
   ],
   "Resource": [
      "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
   ]
}
```

No additional destination bucket permissions are required for annotation replication. The `s3:ReplicateObject` permission on the destination bucket covers annotation replication.

Note the following behaviors for annotation replication:

- Annotation additions and updates on the source are replicated to the destination. Each annotation replicates independently as changes occur.
- Annotation deletions on the source are not replicated to the destination. If you delete an annotation on the source, the annotation persists on the destination.
- If you repeatedly delete and recreate annotations on the source with different names, annotations accumulate on the destination over time because deletions are not replicated.

If you don't want annotations to replicate to a destination bucket, the destination bucket owner can add a Deny statement for the `s3:ReplicateObjectAnnotation` action to the destination bucket policy. Object replication continues to succeed; only annotation replication is blocked. The following example shows the Deny statement:

```
...
   "Statement":[
      {
         "Effect":"Deny",
         "Principal":{
            "AWS":"arn:aws:iam::source-bucket-account-id:role/service-role/source-
account-IAM-role"
         },
         "Action":"s3:ReplicateObjectAnnotation",
         "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      }
   ]
```

```
...
```

For more information about annotation replication behavior, see the section called "What's replicated?". For permission setup instructions, see Setting up permissions for live replication.

Managing or pausing live replication

Live replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. After you set up your replication configuration, Amazon S3 replicates newly created objects and object updates from a source bucket to one or more specified destination buckets.

You use the Amazon S3 console to add replication rules to the source bucket. Replication rules define the source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. For more information about replication, see Replicating objects within and across Regions.

You can manage replication rules on the **Replication** page in the Amazon S3 console. You can add, view, edit, enable, disable, or delete replication rules. You can also change the priority of your replication rules. For information about adding replication rules to a bucket, see Using the S3 console.

To manage the replication rules for a bucket by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. On the **General purpose buckets** tab, choose the name of the bucket that you want.
4. Choose the **Management** tab, and then scroll down to **Replication rules**.
5. You can change your replication rules in the following ways:
   - To enable or disable a replication rule, choose the option button to the left of the rule. On the **Actions** menu, choose **Enable rule** or **Disable rule**. You can also disable, enable, or delete all the rules in the bucket from the **Actions** menu.

     Note

     If you disable a replication rule and then later re-enable the rule, any new or changed objects that weren't replicated while the rule was disabled are *not*

automatically replicated when the rule is re-enabled. To replicate those objects, you must use S3 Batch Replication. For more information, see the section called "Replicating existing objects".

- To change the priority of a rule, choose the option button to the left of the rule, and then choose **Edit rule**.

  You set rule priorities to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see Replication configuration file elements.

Pausing or stopping replication

To temporarily pause replication and have it automatically resume later, you can use the `aws:s3:bucket-pause-replication` action in AWS Fault Injection Service. For more information, see aws:s3:bucket-pause-replication and Pause S3 Replication in the *AWS Fault Injection Service User Guide*.

To stop replication in Amazon S3, we recommend disabling your replication rules. If you disable a replication rule and then later re-enable the rule, any new or changed objects that weren't replicated while the rule was disabled are *not* automatically replicated when the rule is re-enabled. To replicate those objects, you must use S3 Batch Replication. For more information, see the section called "Replicating existing objects".

Replication will also stop if you remove the AWS Identity and Access Management (IAM) role, the AWS Key Management Service (AWS KMS) permissions, or the bucket policy permissions that grant Amazon S3 the required permissions. However, we don't recommend these approaches because they cause replication to fail. Amazon S3 reports the replication status for affected objects as `FAILED`. If permissions are later restored, objects marked as `FAILED` are *not* automatically replicated. To replicate those objects, you must use S3 Batch Replication.

Replicating existing objects with Batch Replication

S3 Batch Replication differs from live replication, which continuously and automatically replicates new objects across Amazon S3 buckets. Instead, S3 Batch Replication occurs on demand on existing objects. You can use S3 Batch Replication to replicate the following types of objects:

- Objects that existed before a replication configuration was in place

- Objects that have previously been replicated
- Objects that have failed replication

You can replicate these objects on demand by using a Batch Operations job.

To get started with Batch Replication, you can:

- **Initiate Batch Replication for a new replication rule or destination** – You can create a one-time Batch Replication job when you're creating the first rule in a new replication configuration or when you're adding a new destination bucket to an existing configuration through the Amazon S3 console.
- **Initiate Batch Replication for an existing replication configuration** – You can create a new Batch Replication job by using S3 Batch Operations through the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

When the Batch Replication job finishes, you receive a completion report. For more information about how to use this report to examine the job, see Tracking job status and completion reports.

S3 Batch Replication considerations

Before using S3 Batch Replication, review the following list of considerations:

- Your source bucket must have an existing replication configuration. To enable replication, see Setting up live replication overview and Examples for configuring live replication.
- If you have S3 Lifecycle configured for your bucket, we recommend disabling your lifecycle rules while the Batch Replication job is active. Doing so helps ensure parity between the source and destination buckets. Otherwise, these buckets could diverge, and the destination bucket won't be an exact replica of the source bucket. For example, consider the following scenario:
  - Your source bucket has multiple versions of an object and a delete marker on that object.
  - Your source and destination buckets have a lifecycle configuration to remove expired delete markers.

  In this scenario, Batch Replication might replicate the delete marker to the destination bucket before replicating the object versions. This behavior could result in your lifecycle configuration marking the delete marker as expired and the delete marker being removed from the destination bucket before the object versions are replicated.

- The AWS Identity and Access Management (IAM) role that you specify to run the Batch Operations job must have the necessary permissions to perform the underlying Batch Replication operation. For more information about creating IAM roles, see Configuring an IAM role for S3 Batch Replication.
- Batch Replication requires a manifest, which can be generated by Amazon S3. The generated manifest must be stored in the same AWS Region as the source bucket. If you choose not to generate the manifest, you can supply an Amazon S3 Inventory report or CSV file that contains the objects that you want to replicate. For more information, see the section called "Specifying a manifest for a Batch Replication job".
- If you recently added or updated the replication configuration on the source bucket, expect a delay of a few minutes before the change is fully propagated. We recommend waiting before creating a Batch Replication job with an S3-generated manifest.
- Batch Replication doesn't support re-replicating objects that were deleted by specifying the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and automatically initiates replication to the destination bucket. Deleting and recreating the destination bucket doesn't initiate replication.

  For more information about Batch Copy, see Examples that use Batch Operations to copy objects.
- If you're using a replication rule on the source bucket, make sure to update your replication configuration by granting the IAM role that's attached to the replication rule the proper permissions to replicate objects. This IAM role must have the necessary permissions to perform replication on both the source and destination buckets.
- If you submit multiple Batch Replication jobs for the same bucket within a short time frame, Amazon S3 runs those jobs concurrently.
- If you submit multiple Batch Replication jobs for two different buckets, be aware that Amazon S3 might not run all jobs concurrently. If you exceed the number of Batch Replication jobs that can run at one time on your account, Amazon S3 pauses the lower priority jobs to work on the higher priority ones. After the higher priority jobs are completed, any paused jobs become active again.
- Batch Replication isn't supported for objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.
- To batch replicate S3 Intelligent-Tiering objects that are stored in the Archive Access or Deep Archive Access storage tiers, you must first initiate a restore request and wait until the objects are moved to the Frequent Access tier.
- A single Batch Replication job can support a manifest with up to 20 billion objects.

- If you use S3 Batch Replication to replicate datasets cross region and your objects previously had their server-side encryption type updated from SSE-S3 to SSE-KMS, you may need additional permissions. On the source region bucket, you must have `kms:decrypt` permissions. Then, you will need the `kms:decrypt` and `kms:encrypt` permissions for the bucket in the destination region. For more information, see Replicating encrypted objects.
- If objects in the source bucket have annotations, the annotations are replicated independently alongside the object during Batch Replication. There are no separate job tasks for individual annotations. The job task status depends on both the parent object replication status and the annotation replication status.
- For best practices for managing incomplete multipart uploads in the destination bucket, see Managing incomplete multipart uploads in destination buckets.

Specifying a manifest for a Batch Replication job

A manifest is an Amazon S3 object that contains the object keys that you want Amazon S3 to act upon. If you want to create a Batch Replication job, you must supply either a user-generated manifest or have Amazon S3 generate a manifest based on your replication configuration.

If you supply a user-generated manifest, it must be in the form of an Amazon S3 Inventory report or a CSV file. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID that's specified in the manifest will be replicated. To learn more about specifying a manifest, see Specifying a manifest.

If you choose to have Amazon S3 generate a manifest file on your behalf, the objects listed use the same source bucket, prefix, and tags as your replication configurations on the source bucket. With a generated manifest, Amazon S3 replicates all eligible versions of your objects.

> **Note**
>
> If you choose to have Amazon S3 generate the manifest, the manifest must be stored in the same AWS Region as the source bucket.

Filters for a Batch Replication job

When creating your Batch Replication job, you can optionally specify additional filters, such as the object creation date and replication status, to reduce the scope of the job.

You can filter objects to replicate based on the `ObjectReplicationStatuses` value, by providing one or more of the following values:

- `"NONE"` – Indicates that Amazon S3 has never attempted to replicate the object before.
- `"FAILED"` – Indicates that Amazon S3 has attempted, but failed, to replicate the object before.
- `"COMPLETED"` – Indicates that Amazon S3 has successfully replicated the object before.
- `"REPLICA"` – Indicates that this object is a replica that Amazon S3 has replicated from another source bucket.

For more information about replication statuses, see Getting replication status information.

If you don't filter your Batch Replication job, Batch Operations attempts to replicate all objects (no matter their `ObjectReplicationStatus`) in your manifest that match the rules in your replication configuration, except for certain objects that aren't replicated by default. For more information, see the section called “What isn't replicated with replication configurations?”

Depending on your goal, you might set `ObjectReplicationStatuses` to one or more of the following values:

- To replicate only existing objects that have never been replicated, only include `"NONE"`.
- To retry replicating only objects that previously failed to replicate, only include `"FAILED"`.
- To both replicate existing objects and retry replicating objects that previously failed to replicate, include both `"NONE"` and `"FAILED"`.
- To backfill a destination bucket with objects that have been replicated to another destination, include `"COMPLETED"`.
- To replicate objects that were previously replicated, include `"REPLICA"`.

Batch Replication completion report

When you create a Batch Replication job, you can request a CSV completion report. This report shows the objects, replication success or failure codes, outputs, and descriptions. For more information about job tracking and completion reports, see Completion reports.

For a list of replication failure codes and descriptions, see Amazon S3 replication failure reasons.

For information about troubleshooting Batch Replication, see Batch Replication errors.

Getting started with Batch Replication

To learn more about how to use Batch Replication, see Create a Batch Replication job for new replication rules or destinations and Create a Batch Replication job for existing replication rules.

Configuring an IAM role for S3 Batch Replication

Because Amazon S3 Batch Replication is a type of Batch Operations job, you must create an AWS Identity and Access Management (IAM) role to grant Batch Operations permissions to perform actions on your behalf. You also must attach a Batch Replication IAM policy to the Batch Operations IAM role.

Use the following procedures to create a policy and an IAM role that give Batch Operations permission to initiate a Batch Replication job.

To create a policy for Batch Replication

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Under **Access management**, choose **Policies**.
3. Choose **Create policy**.
4. On the **Specify permissions** page, choose **JSON**.
5. Insert one of the following policies, depending on whether your manifest is generated by Amazon S3 or whether you are supplying your own manifest. For more information about manifests, see Specifying a manifest for a Batch Replication job.

   Before using these policies, replace the *`user input placeholders`* in the following policies with the names of your replication source bucket, manifest bucket, and completion report bucket.

   > **Note**
   >
   > Your IAM role for Batch Replication needs different permissions, depending on whether you are generating a manifest or supplying one, so make sure that you choose the appropriate policy from the following examples.

   #### Policy if using and storing an Amazon S3 generated manifest

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Action": [
            "s3:InitiateReplication"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
         ]
      },
      {
         "Action": [
            "s3:GetReplicationConfiguration",
            "s3:PutInventoryConfiguration"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-source-bucket"
         ]
      },
      {
         "Action": [
            "s3:GetObject",
            "s3:GetObjectVersion"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*",
            "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
```

```
         ]
      }
   ]
}
```

Policy if using a user-supplied manifest

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Action": [
            "s3:InitiateReplication"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
         ]
      },
      {
         "Action": [
            "s3:GetObject",
            "s3:GetObjectVersion"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*"
         ]
      }
   ]
```

```
}
```

6. Choose **Next**.
7. Specify a name for the policy, and then choose **Create policy**.

To create an IAM role for Batch Replication

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Under **Access management**, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service** as the type of trusted entity. In the **Use case** section, choose **S3** as the service, and **S3 Batch Operations** as the use case.
5. Choose **Next**. The **Add permissions** page appears. In the search box, search for the policy that you created in the preceding procedure. Select the checkbox next to the policy name, then choose **Next**.
6. On the **Name, review, and create** page, specify a name for your IAM role.
7. In the **Step 1: Trust identities** section, verify that your IAM role is using the following trust policy:

   JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Service":"batchoperations.s3.amazonaws.com"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

8. In the **Step 2: Add permissions** section, verify that your IAM role is using the policy that you created earlier.

9. Choose **Create role**.

Create a Batch Replication job for new replication rules or destinations

In Amazon S3, live replication doesn't replicate any objects that already existed in your source bucket before you created a replication configuration. Live replication automatically replicates only new and updated objects that are written to the bucket after the replication configuration is created. To replicate already existing objects, you can use S3 Batch Replication to replicate these objects on demand.

When you create the first rule in a new live replication configuration or add a new destination bucket to an existing replication configuration through the Amazon S3 console, you can optionally create a Batch Replication job. You can use this Batch Replication job to replicate existing objects in the source bucket to the destination bucket.

To use Batch Replication for an existing configuration without adding a new destination bucket, see Create a Batch Replication job for existing replication rules.

Prerequisites

Before creating your Batch Replication job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. For more information, see Configuring an IAM role for S3 Batch Replication.

Using Batch Replication for a new replication rule or destination through the Amazon S3 console

When you create the first rule in a new replication configuration or add a new destination bucket to an existing configuration through the Amazon S3 console, you can choose to create a Batch Replication job to replicate existing objects in the source bucket.

To create a Batch Replication job when creating or updating a replication configuration

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that contains the objects that you want to replicate.

4. To create a new replication rule or edit an existing rule, choose the **Management** tab, and scroll down to **Replication rules**:

   - To create a new replication rule, choose **Create replication rule**. For examples of how to set up a basic replication rule, see Examples for configuring live replication.
   - To edit an existing replication rule, select the option button next to the rule name, and then choose **Edit rule**.

5. Create your new replication rule or edit the destination for your existing replication rule, and choose **Save**.

   After you create the first rule in a new replication configuration or edit an existing configuration to add a new destination, a **Replicate existing objects?** dialog appears, giving you the option to create a Batch Replication job.

6. If you want to create and run this job now, choose **Yes, replicate existing objects**.

   If you want to create a Batch Replication job at a later time, choose **No, do not replicate existing objects**.

7. If you chose **Yes, replicate existing objects**, the **Create Batch Operations job** page appears. The S3 Batch Replication job has the following settings:

   Job run options

   If you want the S3 Batch Replication job to run immediately, choose **Automatically run the job when it's ready**. If you want to run the job at a later time, choose **Wait to run the job when it's ready**.

   > **Note**
   >
   > If you choose **Automatically run the job when it's ready**, you won't be able to create and save a Batch Operations manifest. To save the Batch Operations manifest, choose **Wait to run the job when it's ready**.

   Batch Operations manifest

   If you chose **Wait to run the job when it's ready**, the **Batch Operations manifest** section appears. The manifest is a list of all of the objects that you want to run the specified action on. You can choose to save the manifest. Similar to S3 Inventory files, the manifest will be

saved as a CSV file and stored in a bucket. To learn more about Batch Operations manifests, see Specifying a manifest.

Completion report

S3 Batch Operations executes one task for each object specified in the manifest. Completion reports provide an easy way to view the results of your tasks in a consolidated format with no additional setup required. You can request a completion report for all tasks or only for failed tasks. To learn more about completion reports, see Completion reports.

Permissions

One of the most common causes of replication failures is insufficient permissions in the provided AWS Identity and Access Management (IAM) role. For information about creating this role, see Configuring an IAM role for S3 Batch Replication. Make sure that you create or choose an IAM role that has the required permissions for Batch Replication.

8. Choose **Save**.

Create a Batch Replication job for existing replication rules

In Amazon S3, live replication doesn't replicate any objects that already existed in your source bucket before you created a replication configuration. Live replication automatically replicates only new and updated objects that are written to the bucket after the replication configuration is created. To replicate already existing objects, you can use S3 Batch Replication to replicate these objects on demand.

You can configure S3 Batch Replication for an existing replication configuration by using the AWS SDKs, AWS Command Line Interface (AWS CLI), or the Amazon S3 console. For an overview of Batch Replication, see Replicating existing objects with Batch Replication.

When the Batch Replication job finishes, you receive a completion report. For more information about how to use the report to examine the job, see Tracking job status and completion reports.

Prerequisites

Before creating your Batch Replication job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. For more information, see Configuring an IAM role for S3 Batch Replication.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. Verify that the **AWS Region** section shows the Region where you want to create your job.
5. In the **Manifest** section, specify the manifest format that you want to use. The manifest is a list of all of the objects that you want to run the specified action on. To learn more about Batch Operations manifests, see Specifying a manifest.

   - If you have a manifest prepared, choose **S3 inventory report (manifest.json)** or **CSV**. If your manifest is in a versioned bucket, you can specify the version ID for the manifest. If you don't specify a version ID, Batch Operations uses the current version of your manifest. For more information about creating a manifest, see Specifying a manifest.

     > **Note**
     >
     > If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. For more information, see Specifying a manifest.

   - To create a manifest based on your replication configuration, choose **Create manifest using S3 Replication configuration**. Then choose the source bucket of your replication configuration.
6. (Optional) If you chose **Create manifest using S3 Replication configuration**, you can include additional filters, such as the object creation date and replication status. For examples of how to filter by replication status, see Specifying a manifest for a Batch Replication job.
7. (Optional) If you chose **Create manifest using S3 Replication configuration**, you can save the generated manifest. To save this manifest, select **Save Batch Operations manifest**. Then specify the destination bucket for the manifest and choose whether to encrypt the manifest.

   > **Note**
   >
   > The generated manifest must be stored in the same AWS Region as the source bucket.

8. Choose **Next**.
9. On the **Operations** page, choose **Replicate**, then choose **Next**.

10. (Optional) Provide a **Description**.
11. Adjust the **Priority** of the job if needed. Higher numbers indicate higher priority. Amazon S3 attempts to run higher priority jobs before lower priority jobs. For more information about job priority, see Assigning job priority.
12. (Optional) Generate a completion report. To generate this report, select **Generate completion report**.

    If you choose to generate a completion report, you must choose either to report **Failed tasks only** or **All tasks**, and provide a destination bucket for the report.
13. In the **Permissions** section, make sure that you choose an IAM role that has the required permissions for Batch Replication. One of the most common causes of replication failures is insufficient permissions in the provided IAM role. For information about creating this role, see Configuring an IAM role for S3 Batch Replication.
14. (Optional) Add job tags to the Batch Replication job.
15. Choose **Next**.
16. Review your job configuration, and then choose **Create job**.

Using the AWS CLI with an S3 manifest

The following example `create-job` command creates an S3 Batch Replication job by using an S3 generated manifest for the AWS account *111122223333*. This example replicates existing objects and objects that previously failed to replicate. For information about filtering by replication status, see Specifying a manifest for a Batch Replication job.

To use this command, replace the *user input placeholders* with your own information. Replace the IAM role `role/`*batch-Replication-IAM-policy* with the IAM role that you previously created. For more information, see Configuring an IAM role for S3 Batch Replication.

```
aws s3control create-job --account-id 111122223333 \
--operation '{"S3ReplicateObject":{}}' \
--report '{"Bucket":"arn:aws:s3:::amzn-s3-demo-completion-report-bucket",\
"Prefix":"batch-replication-report", \
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}' \
--manifest-generator '{"S3JobManifestGenerator": {"ExpectedBucketOwner":
 "111122223333", \
"SourceBucket": "arn:aws:s3:::amzn-s3-demo-source-bucket", \
"EnableManifestOutput": false, "Filter": {"EligibleForReplication": true, \
```

```
"ObjectReplicationStatuses": ["NONE","FAILED"]}}}' \
--priority 1 \
--role-arn arn:aws:iam::111122223333:role/batch-Replication-IAM-policy \
--no-confirmation-required \
--region source-bucket-region
```

> **Note**
>
> You must initiate the job from the same AWS Region as the replication source bucket.

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job by using the following `describe-job` command. To use this command, replace the *`user input placeholders`* with your own information.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Using the AWS CLI with a user-provided manifest

The following example creates an S3 Batch Replication job by using a user-defined manifest for AWS account *`111122223333`*. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID specified in the manifest will be replicated. For more information about creating a manifest, see Specifying a manifest.

To use this command, replace the *`user input placeholders`* with your own information. Replace the IAM role `role/`*`batch-Replication-IAM-policy`* with the IAM role that you previously created. For more information, see Configuring an IAM role for S3 Batch Replication.

```
aws s3control create-job --account-id 111122223333 \
--operation '{"S3ReplicateObject":{}}' \
--report '{"Bucket":"arn:aws:s3:::amzn-s3-demo-completion-report-bucket",\
"Prefix":"batch-replication-report", \
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}' \
--manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820",\
"Fields":["Bucket","Key","VersionId"]},\
"Location":{"ObjectArn":"arn:aws:s3:::amzn-s3-demo-manifest-bucket/manifest.csv",\
"ETag":"Manifest Etag"}}' \
--priority 1 \
--role-arn arn:aws:iam::111122223333:role/batch-Replication-IAM-policy \
```

```
--no-confirmation-required \
--region source-bucket-region
```

> **Note**
>
> You must initiate the job from the same AWS Region as the replication source bucket.

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job by using the following `describe-job` command.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Troubleshooting replication

This section lists troubleshooting tips for Amazon S3 Replication and information about S3 Batch Replication errors.

Topics

- Troubleshooting tips for S3 Replication
- Batch Replication errors

Troubleshooting tips for S3 Replication

If object replicas don't appear in the destination bucket after you configure replication, use these troubleshooting tips to identify and fix issues.

- The majority of objects replicate within 15 minutes. The time that it takes Amazon S3 to replicate an object depends on several factors, including the source and destination Region pair, and the size of the object. For large objects, replication can take up to several hours. For visibility into replication times, you can use S3 Replication Time Control (S3 RTC).

  If the object that is being replicated is large, wait a while before checking to see whether it appears in the destination. You can also check the replication status of the source object. If the object replication status is `PENDING`, Amazon S3 hasn't completed the replication. If the object replication status is `FAILED`, check the replication configuration that's set on the source bucket.

Additionally, to receive information about failures during replication, you can set up Amazon S3 Event Notifications replication to receive failure events. For more information, see Receiving replication failure events with Amazon S3 Event Notifications.

- To check the replication status of an object, you can call the `HeadObject` API operation. The `HeadObject` API operation returns the `PENDING`, `COMPLETED`, or `FAILED` replication status of an object. In a response to a `HeadObject` API call, the replication status is returned in the `x-amz-replication-status` header.

  > **Note**
  >
  > To run `HeadObject`, you must have read access to the object that you're requesting. A `HEAD` request has the same options as a `GET` request, without performing a `GET` operation. For example, to run a `HeadObject` request by using the AWS Command Line Interface (AWS CLI), you can run the following command. Replace the *`user input placeholders`* with your own information.
  >
  > ```
  > aws s3api head-object --bucket amzn-s3-demo-source-bucket --key index.html
  > ```

- If `HeadObject` returns objects with a `FAILED` replication status, you can use S3 Batch Replication to replicate those failed objects. For more information, see the section called "Replicating existing objects". Alternatively, you can re-upload the failed objects to the source bucket, which will initiate replication for the new objects.

  > **Note**
  >
  > If your replication rule uses the change object ownership to the destination bucket owner option and the object exists in the destination bucket but shows a `FAILED` replication status, S3 Batch Replication might not resolve this status. If you encounter this situation, contact AWS Support to verify the replication state of the affected objects.

- In the replication configuration on the source bucket, verify the following:
  - The Amazon Resource Name (ARN) of the destination bucket is correct.
  - The key name prefix is correct. For example, if you set the configuration to replicate objects with the prefix `Tax`, then only objects with key names such as `Tax/document1` or `Tax/document2` are replicated. An object with the key name `document3` is not replicated.

  - The status of the replication rule is `Enabled`.
- Verify that versioning hasn't been suspended on any bucket in the replication configuration. Both the source and destination buckets must have versioning enabled.
- If a replication rule is set to **Change object ownership to the destination bucket owner**, then the AWS Identity and Access Management (IAM) role that's used for replication must have the `s3:ObjectOwnerOverrideToBucketOwner` permission. This permission is granted on the resource (in this case, the destination bucket). For example, the following `Resource` statement shows how to grant this permission on the destination bucket:

```
{
  "Effect":"Allow",
  "Action":[
    "s3:ObjectOwnerOverrideToBucketOwner"
  ],
  "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
```

- If the destination bucket is owned by another account, the owner of the destination bucket must also grant the `s3:ObjectOwnerOverrideToBucketOwner` permission to the source bucket owner through the destination bucket policy. To use the following example bucket policy, replace the *`user input placeholders`* with your own information:

  JSON

```
{
  "Version":"2012-10-17",
  "Id": "Policy1644945280205",
  "Statement": [
    {
      "Sid": "Stmt1644945277847",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"
      },
      "Action": [
        "s3:ReplicateObject",
        "s3:ReplicateTags",
        "s3:ObjectOwnerOverrideToBucketOwner"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
    }
```

```
  ]
}
```

> **Note**
>
> If the destination bucket's object ownership settings include **Bucket owner enforced**, then you don't need to update the setting to **Change object ownership to the destination bucket owner** in the replication rule. The object ownership change will occur by default. For more information about changing replica ownership, see Changing the replica owner.

- If you're setting the replication configuration in a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, the destination buckets can't be configured as a Requester Pays bucket. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.
- If a bucket's source objects are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), then the replication rule must be configured to include AWS KMS-encrypted objects. Make sure to select **Replicate objects encrypted with AWS KMS** under your **Encryption** settings in the Amazon S3 console. Then, select an AWS KMS key for encrypting the destination objects.

> **Note**
>
> If the destination bucket is in a different account, specify an AWS KMS customer managed key that is owned by the destination account. Don't use the default Amazon S3 managed key (`aws/s3`). Using the default key encrypts the objects with the Amazon S3 managed key that's owned by the source account, preventing the object from being shared with another account. As a result, the destination account won't be able to access the objects in the destination bucket.

To use an AWS KMS key that belongs to the destination account to encrypt the destination objects, the destination account must grant the `kms:GenerateDataKey` and `kms:Encrypt` permissions to the replication role in the KMS key policy. To use the following example statement in your KMS key policy, replace the *`user input placeholders`* with your own information:

```
{
    "Sid": "AllowS3ReplicationSourceRoleToUseTheKey",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"
    },
    "Action": ["kms:GenerateDataKey", "kms:Encrypt"],
    "Resource": "*"
}
```

If you use an asterisk (*) for the `Resource` statement in the AWS KMS key policy, the policy grants permission to use the KMS key to only the replication role. The policy doesn't allow the replication role to elevate its permissions.

By default, the KMS key policy grants the root user full permissions to the key. These permissions can be delegated to other users in the same account. Unless there are `Deny` statements in the source KMS key policy, using an IAM policy to grant the replication role permissions to the source KMS key is sufficient.

> **Note**
>
> KMS key policies that restrict access to specific CIDR ranges, virtual private cloud (VPC) endpoints, or S3 access points can cause replication to fail.

If either the source or destination KMS keys grant permissions based on the encryption context, confirm that Amazon S3 Bucket Keys are turned on for the buckets. If the buckets have S3 Bucket Keys turned on, the encryption context must be the bucket-level resource, like this:

```
"kms:EncryptionContext:arn:aws:arn": [
     "arn:aws:s3:::amzn-s3-demo-source-bucket"
     ]
"kms:EncryptionContext:arn:aws:arn": [
     "arn:aws:s3:::amzn-s3-demo-destination-bucket"
     ]
```

In addition to the permissions granted by the KMS key policy, the source account must add the following minimum permissions to the replication role's IAM policy:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "Source-KMS-Key-ARN"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey",
        "kms:Encrypt"
    ],
    "Resource": [
        "Destination-KMS-Key-ARN"
    ]
}
```

Important

If you use S3 Batch Replication to replicate datasets cross region and your objects previously had their server-side encryption type updated from SSE-S3 to SSE-KMS, you may need additional permissions. On the source region bucket, you must have `kms:decrypt` permissions. Then, you will need the `kms:decrypt` and `kms:encrypt` permissions for the bucket in the destination region.

For more information about how to replicate objects that are encrypted with AWS KMS, see Replicating encrypted objects.

- If the destination bucket is owned by another AWS account, verify that the bucket owner has a bucket policy on the destination bucket that allows the source bucket owner to replicate objects. For an example, see Configuring replication for buckets in different accounts.
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`.

If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see the section called "Using Object Lock with S3 Replication".

- If your objects still aren't replicating after you've validated the permissions, check for any explicit `Deny` statements in the following locations:
  - `Deny` statements in the source or destination bucket policies. Replication fails if the bucket policy denies access to the replication role for any of the following actions:

    Source bucket:

    ```
    "s3:GetReplicationConfiguration",
    "s3:ListBucket",
    "s3:GetObjectVersionForReplication",
    "s3:GetObjectVersionAcl",
    "s3:GetObjectVersionTagging"
    ```

    Destination buckets:

    ```
    "s3:ReplicateObject",
    "s3:ReplicateDelete",
    "s3:ReplicateTags"
    ```

  - `Deny` statements or permissions boundaries attached to the IAM role can cause replication to fail.
  - `Deny` statements in AWS Organizations service control policies (SCPs) that are attached to either the source or destination accounts can cause replication to fail.
  - `Deny` statements in AWS Organizations resource control policies (RCPs) that are attached to either the source or destination buckets can cause replication to fail.
- If an object replica doesn't appear in the destination bucket, the following issues might have prevented replication:
  - Amazon S3 doesn't replicate an object in a source bucket that is a replica created by another replication configuration. For example, if you set a replication configuration from bucket A to bucket B to bucket C, Amazon S3 doesn't replicate object replicas in bucket B to bucket C.
  - A source bucket owner can grant other AWS accounts permission to upload objects. By default, the source bucket owner doesn't have permissions for the objects created by other accounts. The replication configuration replicates only the objects for which the source bucket owner has access permissions. To avoid this problem, the source bucket owner can grant other AWS accounts permissions to create objects conditionally, requiring explicit access permissions on

those objects. For an example policy, see Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control.

- Suppose that in the replication configuration, you add a rule to replicate a subset of objects that have a specific tag. In this case, you must assign the specific tag key and value at the time the object is created in order for Amazon S3 to replicate the object. If you first create an object and then add the tag to the existing object, Amazon S3 doesn't replicate the object.
- Use Amazon S3 Event Notifications to notify you of instances when objects don't replicate to their destination AWS Region. Amazon S3 Event Notifications are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see Receiving replication failure events with Amazon S3 Event Notifications.

  You can also view replication failure reasons by using Amazon S3 Event Notifications. To review the list of failure reasons, see Amazon S3 replication failure reasons.

Batch Replication errors

To troubleshoot objects that aren't replicating to the destination bucket, check the different types of permissions for your buckets, replication role, and IAM role that's used to create the Batch Replication job. Also, make sure to check the Block Public Access settings and S3 Object Ownership settings for your buckets.

For additional troubleshooting tips for working with Batch Operations, see the section called "Troubleshooting S3 Batch Operations".

If you've set up replication and objects aren't replicating, see Why aren't my Amazon S3 objects replicating when I set up replication between my buckets? in the AWS re:Post Knowledge Center.

While using Batch Replication, you might encounter one of these errors:

- Manifest generation found no keys matching the filter criteria.

  This error occurs for one of the following reasons:

  - When objects in the source bucket are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

    To use Batch Replication on these objects, first restore them to the S3 Standard storage class by using a **Restore** (`S3InitiateRestoreObjectOperation`) operation in a Batch

Operations job. For more information, see Restoring an archived object and Restore objects (Batch Operations). After you've restored the objects, you can replicate them by using a Batch Replication job.

- When the provided filter criteria doesn't match any valid objects in the source bucket.

  Verify and correct the filter criteria. For example, in the Batch Replication rule, the filter criteria is looking for all objects in the source bucket with the prefix `Tax/`. If the prefix name was entered inaccurately, with a slash in the beginning and the end `/Tax/` instead of only at the end, then no S3 objects were found. To resolve the error, correct the prefix, in this case, from `/Tax/` to `Tax/` in the replication rule.

- Batch operation status is failed with reason: The job report could not be written to your report bucket.

  This error occurs if the IAM role that's used for the Batch Operations job is unable to put the completion report into the location that was specified when you created the job. To resolve this error, check that the IAM role has the `s3:PutObject` permission for the bucket where you want to save the Batch Operations completion report. We recommend delivering the report to a bucket different from the source bucket.

- Batch operation is completed with failures and Total failed is not 0.

  This error occurs if there are insufficient object permissions issues with the Batch Replication job that is running. If you're using a replication rule for your Batch Replication job, make sure that the IAM role that's used for replication has the proper permissions to access objects from either the source or destination bucket. You can also check the Batch Replication completion report to review the specific Amazon S3 replication failure reason.

- Batch job ran successfully but the number of objects expected in destination bucket is not the same.

  This error occurs when there's a mismatch between the objects listed in the manifest that's supplied in the Batch Replication job and the filters that you selected when you created the job. You might also receive this message when the objects in your source bucket don't match any replication rules and aren't included in the generated manifest.

Batch Operations failures occur after adding a new replication rule to an existing replication configuration

Batch Operations attempts to perform existing object replication for every rule in the source bucket's replication configuration. If there are problems with any of the existing replication rules, failures might occur.

The Batch Operations job's completion report explains the job failure reasons. For a list of common errors, see Amazon S3 replication failure reasons.

Monitoring replication with metrics, event notifications, and statuses

You can monitor your live replication configurations and your S3 Batch Replication jobs through the following mechanisms:

- **S3 Replication metrics** – When you enable S3 Replication metrics, Amazon CloudWatch emits metrics that you can use to track bytes pending, operations pending, and replication latency at the replication rule level. You can view S3 Replication metrics through the Amazon S3 console and the Amazon CloudWatch console. In the Amazon S3 console, you can view these metrics in the source bucket's **Metrics** tab. For more information about S3 Replication metrics, see the section called “Using S3 Replication metrics”.
- **S3 Storage Lens metrics** – In addition to S3 Replication metrics, you can use the replication-related Data Protection metrics provided by S3 Storage Lens dashboards. For example, if you use the free metrics in S3 Storage Lens, you can see metrics such as the total number of bytes that are replicated from the source bucket or the count of replicated objects from the source bucket.

  To audit your overall replication stance, you can enable advanced metrics in S3 Storage Lens. With advanced metrics in S3 Storage Lens, you can see how many replication rules you have of various types, including the count of replication rules with a replication destination that's not valid.

  For more information about working with replication metrics in S3 Storage Lens, see the section called “Viewing replication metrics in S3 Storage Lens dashboards”.
- **S3 Event Notifications** – S3 Event Notifications can notify you at the object level in instances when objects don't replicate to their destination AWS Region or when objects aren't replicated within certain thresholds. S3 Event Notifications provides the following replication event types: `s3:Replication:OperationFailedReplication`, `s3:Replication:OperationMissedThreshold`,

`s3:Replication:OperationReplicatedAfterThreshold`, and `s3:Replication:OperationNotTracked`.

Amazon S3 events are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see the section called "Receiving replication failure events".

- **Replication status values** – You can also retrieve the replication status of your objects. The replication status can help you determine the current state of an object that's being replicated. The replication status of a source object will return either `PENDING`, `COMPLETED`, or `FAILED`. The replication status of a replica will return `REPLICA`.

  You can also use replication status values when you're creating S3 Batch Replication jobs. For example, you can use these status values to replicate objects that have either never been replicated or that have failed replication.

  For more information about retrieving the replication status of your objects, see the section called "Getting replication status". For more information about using these values with Batch Replication, see the section called "Filters for a Batch Replication job".

- Receiving replication failure events with Amazon S3 Event Notifications
- Getting replication status information

Using S3 Replication metrics

S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

Note

- S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For more information, see Amazon CloudWatch pricing.

- If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule.

S3 Replication metrics are turned on automatically when you enable S3 Replication Time Control (S3 RTC). You can also enable S3 Replication metrics independently of S3 RTC while creating or editing a rule. S3 RTC includes other features, such as a service level agreement (SLA) and notifications for missed thresholds. For more information, see Meeting compliance requirements with S3 Replication Time Control.

When S3 Replication metrics are enabled, Amazon S3 publishes the following metrics to Amazon CloudWatch. CloudWatch metrics are delivered on a best-effort basis.

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Bytes Pending Replication	The total number of bytes of objects that are pending replication for a given replication rule.	This metric applies only to new objects that are replicated with S3 Cross-Region Replication (S3 CRR) or S3 Same-Region Replication (S3 SRR).	This metric is published in the Region of the destination bucket.	No	Yes
Replication Latency	The maximum number of	This metric applies only to new	This metric is published in the Region of	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
	seconds by which the replication destination bucket is behind the source bucket for a given replication rule.	objects that are replicated with S3 CRR or S3 SRR.	the destination bucket.		

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Operations Pending Replication	The number of operations that are pending replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and S3 Object Lock.	This metric applies only to new objects that are replicated with S3 CRR or S3 SRR.	This metric is published in the Region of the destination bucket.	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Operations Failed Replication	The number of operations that failed replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and Object Lock. **Operations Failed Replication** tracks S3 Replication failures aggregated at a per-minute interval. To identify the specific	This metric applies both to new objects that are replicated with S3 CRR or S3 SRR and also to existing objects that are replicated with S3 Batch Replication. **Note** If an S3 Batch Replication job fails to run at all, metrics aren't sent	This metric is published in the Region of the source bucket.	Yes	No

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
	objects that have failed replication and their failure reasons, subscribe to the `Operation FailedReplication` event in Amazon S3 Event Notifications. For more information, see Receiving replication failure events with Amazon S3 Event Notifications.	to Amazon CloudWatch. For example, your job won't run if you don't have the necessary permissions to run an S3 Batch Replication job, or if the tags or prefix in your replicati			

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
		on configuration don't match.			

For information about working with these metrics in CloudWatch, see the section called "S3 Replication metrics in CloudWatch".

Enabling S3 Replication metrics

You can start using S3 Replication metrics with a new or existing replication rule. For full instructions on creating replication rules, see Configuring replication for buckets in the same account. You can choose to apply your replication rule to an entire S3 bucket, or to Amazon S3 objects with a specific prefix or tag.

This topic provides instructions for enabling S3 Replication metrics in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replication metrics by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with `Metrics` enabled. In this example configuration, objects under the prefix *`Tax`* are replicated to the destination bucket *`amzn-s3-demo-bucket`*, and metrics are generated for those objects.

```
{
    "Rules": [
        {
            "Status": "Enabled",
            "Filter": {
                "Prefix": "Tax"
```

```
            },
            "Destination": {
                "Bucket": "arn:aws:s3:::amzn-s3-demo-bucket",
                "Metrics": {
                    "Status": "Enabled"
                }
            },
            "Priority": 1
        }
    ],
    "Role": "IAM-Role-ARN"
}
```

Viewing replication metrics

You can view S3 Replication metrics in the source general purpose bucket's **Metrics** tab in the Amazon S3 console. These Amazon CloudWatch metrics are also available in the Amazon CloudWatch console. When you enable S3 Replication metrics, Amazon CloudWatch emits metrics that you can use to track bytes pending, operations pending, and replication latency at the replication rule level.

S3 Replication metrics are turned on automatically when you enable replication with S3 Replication Time Control (S3 RTC) by using the Amazon S3 console or the Amazon S3 REST API. You can also enable S3 Replication metrics independently of S3 RTC while creating or editing a rule.

If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule. For more information, see Using S3 Replication metrics.

Replication metrics track the rule IDs of the replication configuration. A replication rule ID can be specific to a prefix, a tag, or a combination of both.

For more information about CloudWatch metrics for Amazon S3, see Monitoring metrics with Amazon CloudWatch.

Prerequisites

Create a replication rule that has S3 Replication metrics enabled. For more information, see the section called “Enabling replication metrics”.

To view S3 Replication metrics through the source bucket's Metrics tab

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the source bucket that contains the objects that you want replication metrics for.
4. Choose the **Metrics** tab.
5. Under **Replication metrics**, choose the replication rules that you want to see metrics for.
6. Choose **Display charts**.

   Amazon S3 displays **Replication latency**, **Bytes pending replication**, **Operations pending replication**, and **Operations failed replication** charts for the rules that you selected.

Viewing replication metrics in S3 Storage Lens dashboards

In addition to S3 Replication metrics, you can use the replication-related Data Protection metrics provided by S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Using S3 Storage Lens to protect your data.

S3 Storage Lens has two tiers of metrics: free metrics, and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

If you use the free metrics in S3 Storage Lens, you can see metrics such as the total number of bytes that are replicated from the source bucket or the count of replicated objects from the source bucket.

To audit your overall replication stance, you can enable advanced metrics in S3 Storage Lens. With advanced metrics in S3 Storage Lens, you can see how many replication rules you have of various types, including the count of replication rules with a replication destination that's not valid.

For a complete list of S3 Storage Lens metrics, including which replication metrics are in each tier, see the S3 Storage Lens metrics glossary.

Prerequisites

Create a live replication configuration or an S3 Batch Replication job.

To view replication metrics in Amazon S3 Storage Lens

1. Create an S3 Storage Lens dashboard. For step-by-step instructions, see the section called "Using the S3 console".
2. (Optional) During your dashboard setup, if you want to see all S3 Storage Lens replication metrics, select **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For a complete list of metrics, see the S3 Storage Lens metrics glossary.

   If you enable advanced metrics and recommendations, you can gain further insights into your replication configurations. For example, you can use S3 Storage Lens replication rule count metrics to get detailed information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions. For more information, see the section called "Count the total number of replication rules for each bucket".
3. After you've created your dashboard, open the dashboard, and choose the **Buckets** tab.
4. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
5. To filter the **Buckets** list to display only replication metrics, choose the **Preferences** icon ().
6. Clear the toggles for all data-protection metrics until only the replication metrics remain selected.
7. (Optional) Under **Page size**, choose the number of buckets to display in the list.
8. Choose **Continue**.

Receiving replication failure events with Amazon S3 Event Notifications

If you've enabled S3 Replication metrics on your replication configuration, you can set up Amazon S3 Event Notifications to notify you when objects don't replicate to their destination AWS Region. If you've enabled S3 Replication Time Control (S3 RTC) on your replication configuration, you can also be notified when objects don't replicate within the 15-minute S3 RTC threshold for replication.

Important

To receive replication failure event notifications (`s3:Replication:OperationFailedReplication`), you must enable S3 Replication metrics on your replication rule. You do not need to enable S3 Replication Time Control (S3 RTC) to receive failure notifications. S3 RTC is only required for threshold-based notifications (`s3:Replication:OperationMissedThreshold` and `s3:Replication:OperationReplicatedAfterThreshold`). You can enable S3 Replication metrics independently of S3 RTC. For more information, see Enabling S3 Replication metrics.

By using the following `Replication` event types, you can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For more information about S3 Replication metrics, see Using S3 Replication metrics.

- The `s3:Replication:OperationFailedReplication` event type notifies you when an object that was eligible for replication failed to replicate.
- The `s3:Replication:OperationMissedThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.
- The `s3:Replication:OperationReplicatedAfterThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.
- The `s3:Replication:OperationNotTracked` event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

For full descriptions of all the supported replication event types, see the section called "Supported event types for SQS, SNS, and Lambda".

For a list of the failure codes captured by S3 Event Notifications, see Amazon S3 replication failure reasons.

You can receive S3 Event Notifications through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see the section called "Amazon S3 Event Notifications".

For instructions on how to configure Amazon S3 Event Notifications, see Enabling event notifications.

The following is an example of a message that Amazon S3 sends to publish an `s3:Replication:OperationFailedReplication` event. For more information, see the section called "Event message structure".

```
{
  "Records": [
    {
      "eventVersion": "2.2",
      "eventSource": "aws:s3",
      "awsRegion": "us-east-1",

      }
    }
  ]
}
```

Amazon S3 replication failure reasons

The following table lists Amazon S3 Replication failure reasons. You can view these reasons by receiving the `s3:Replication:OperationFailedReplication` event with Amazon S3 Event Notifications and then looking at the `failureReason` value.

You can also view these failure reasons in an S3 Batch Replication completion report. For more information, see Batch Replication completion report.

Replication failure reason	Description
`AssumeRoleNotPermitted`	Amazon S3 can't assume the AWS Identity and Access Management (IAM) role that's specified in the replication configuration or in the Batch Operations job.
`DstBucketInvalidRegion`	The destination bucket is not in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
`DstBucketNotFound`	Amazon S3 is unable to find the destinati on bucket that's specified in the replication configuration.
`DstBucketObjectLockConfigMissing`	To replicate objects from a source bucket with Object Lock enabled, the destination bucket must also have Object Lock enabled.

Replication failure reason	Description
	This error indicates that Object Lock might not be enabled in the destination bucket. For more information, see Object Lock considerations.
`DstBucketUnversioned`	Versioning is not enabled for the S3 destination bucket. To replicate objects with S3 Replication, enable versioning for the destination bucket.
`DstDelObjNotPermitted`	Amazon S3 is unable to replicate delete markers to the destination bucket. The `s3:ReplicateDelete` permission might be missing for the destination bucket.
`DstKmsKeyInvalidState`	The AWS Key Management Service (AWS KMS) key for the destination bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the *AWS Key Management Service Developer Guide*.
`DstKmsKeyNotFound`	The AWS KMS key that's configured for the destination bucket in the replication configuration doesn't exist.
`DstMultipartCompleteNotPermitted`	Amazon S3 is unable to complete multipart uploads of objects in the destination bucket. The `s3:ReplicateObject` permission might be missing for the destination bucket.
`DstMultipartInitNotPermitted`	Amazon S3 is unable to initiate multipart uploads of objects to the destination bucket. The `s3:ReplicateObject` permission might be missing for the destination bucket.

Replication failure reason	Description
DstMultipartUploadNotPermitted	Amazon S3 is unable to upload multipart upload objects to the destination bucket. The s3:ReplicateObject permission might be missing for the destination bucket.
DstObjectHardDeleted	S3 Batch Replication does not support re-replicating objects deleted with the version ID of the object from the destination bucket. This error is specific to Batch Replication.
DstPutAclNotPermitted	Amazon S3 is unable to replicate object access control lists (ACLs) to the destination bucket. The s3:ReplicateObject permission might be missing for the destination bucket.
DstPutLegalHoldNotPermitted	Amazon S3 is unable to put an Object Lock legal hold on the destination objects when it's replicating immutable objects. The s3:PutObjectLegalHold permission might be missing for the destination bucket. For more information, see Legal holds.
DstPutObjectNotPermitted	Amazon S3 is unable to replicate objects to the destination bucket. This can occur when required permissions (s3:ReplicateObject or s3:ObjectOwnerOverrideToBucketOwner permissions) are missing for the destination bucket or when the AWS KMS key policy doesn't allow the source bucket's replication role to use the AWS KMS key (kms:Decrypt and kms:GenerateDataKey* actions) at the destination bucket.

Replication failure reason	Description
DstPutRetentionNotPermitted	Amazon S3 is unable to put a retention period on the destination objects when it's replicating immutable objects. The s3:PutObjectRetention permission might be missing for the destination bucket.
DstPutTaggingNotPermitted	Amazon S3 is unable to replicate object tags to the destination bucket. The s3:ReplicateObject permission might be missing for the destination bucket.
DstVersionNotFound	Amazon S3 is unable to find the required object version in the destination bucket for which metadata needs to be replicated.
InitiateReplicationNotPermitted	Amazon S3 is unable to initiate replication on objects. The s3:InitiateReplication permission might be missing for the Batch Operations job. This error is specific to Batch Replication.
SrcBucketInvalidRegion	The source bucket isn't in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
SrcBucketNotFound	Amazon S3 is unable to find the source bucket.
SrcBucketReplicationConfigMissing	Amazon S3 couldn't find a replication configuration for the source bucket.

Replication failure reason	Description
SrcGetAclNotPermitted	Amazon S3 is unable to access the object in the source bucket for replication. The s3:GetObjectVersionAcl permission might be missing for the source bucket object. The objects in the source bucket must be owned by the bucket owner. If ACLs are enabled, then verify if Object Ownership is set to Bucket owner preferred or Object writer. If Object Ownership is set to Bucket owner preferred, then the source bucket objects must have the bucket-owner-full-control ACL for the bucket owner to become the object owner. The source account can take ownership of all objects in their bucket by setting Object Ownership to Bucket owner enforced and disabling ACLs.
SrcGetLegalHoldNotPermitted	Amazon S3 is unable to access the S3 Object Lock legal hold information.
SrcGetObjectNotPermitted	Amazon S3 is unable to access the object in the source bucket for replication. The s3:GetObjectVersionForReplication permission might be missing for the source bucket.
SrcGetRetentionNotPermitted	Amazon S3 is unable to access the S3 Object Lock retention period information.
SrcGetTaggingNotPermitted	Amazon S3 is unable to access object tag information from the source bucket. The s3:GetObjectVersionTagging permission might be missing for the source bucket.

Replication failure reason	Description
SrcHeadObjectNotPermitted	Amazon S3 is unable to retrieve object metadata from the source bucket. The s3:GetObjectVersionForReplication permission might be missing for the source bucket.
SrcKeyNotFound	Amazon S3 is unable to find the source object key to replicate. Source object may have been deleted before replication was complete.
SrcKmsKeyInvalidState	The AWS KMS key for the source bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the *AWS Key Management Service Developer Guide*.
SrcObjectNotEligible	Some objects aren't eligible for replication. This may be due to the object's storage class or the object tags don't match the replication configuration.
SrcObjectNotFound	Source object does not exist.
SrcReplicationNotPending	Amazon S3 has already replicated this object. This object is no longer pending replication.
SrcVersionNotFound	Amazon S3 is unable to find the source object version to replicate. Source object version may have been deleted before replication was complete.

Replication failure reason	Description
SrcAnnotationNotFound	Source annotation was not found. The annotation was deleted before replication completed.
SrcGetObjectAnnotationNotPermitted	Access denied when retrieving the source annotation for replication. The IAM role is missing s3:GetObjectVersionAnnotationForReplication .
DstPutObjectAnnotationNotPermitted	Access denied when replicating the annotation to the destination bucket. The IAM role is missing s3:ReplicateObject or does not have access to the required AWS KMS key.
SrcAnnotationEncryptionUnsupported	The object annotation encryption type is not supported.
AnnotationLimitExceeded	The object annotation count exceeds the limit (1000). Replication would exceed the annotation limit on the destination.

Troubleshooting replication

Getting replication status information

Replication status can help you determine the current state of an object being replicated. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

You can also use replication status values when you're creating S3 Batch Replication jobs. For example, you can use these status values to replicate objects that have either never been replicated or that have failed replication. For more information about using these values with Batch

Replication, see the section called "Using replication status information with Batch Replication jobs".

Topics

- Replication status overview
- Replication status if replicating to multiple destination buckets
- Replication status if Amazon S3 replica modification sync is enabled

- Finding replication status

Replication status overview

In replication, you have a source bucket on which you configure replication and one or more destination buckets where Amazon S3 replicates objects. When you request an object (by using `GetObject`) or object metadata (by using `HeadObject`) from these buckets, Amazon S3 returns the `x-amz-replication-status` header in the response:

- When you request an object from the source bucket, Amazon S3 returns the `x-amz-replication-status` header if the object in your request is eligible for replication.

  For example, suppose that you specify the object prefix `TaxDocs` in your replication configuration to tell Amazon S3 to replicate only objects with the key name prefix `TaxDocs`. Any objects that you upload that have this key name prefix—for example, `TaxDocs/document1.pdf`—will be replicated. For object requests with this key name prefix, Amazon S3 returns the `x-amz-replication-status` header with one of the following values for the object's replication status: `PENDING`, `COMPLETED`, or `FAILED`.

  > **Note**
  >
  > If object replication fails after you upload an object, you can't retry replication. You must upload the object again, or you must use S3 Batch Replication to replicate any failed objects. S3 Lifecycle blocks expiration and transition actions on objects with `PENDING` or `FAILED` replication status. For more information about using Batch Replication, see the section called "Replicating existing objects".
  >
  > Objects transition to a `FAILED` state for issues such as missing replication role permissions, AWS Key Management Service (AWS KMS) permissions, or bucket permissions. For temporary failures, such as if a bucket or Region is unavailable,

replication status doesn't transition to `FAILED`, but remains `PENDING`. After the resource is back online, Amazon S3 resumes replicating those objects.

- When you request an object from a destination bucket, if the object in your request is a replica that Amazon S3 created, Amazon S3 returns the `x-amz-replication-status` header with the value `REPLICA`.

> **Note**
>
> Before deleting an object from a source bucket that has replication enabled, check the object's replication status to make sure that the object has been replicated.
> If an S3 Lifecycle configuration is enabled on the source bucket, Amazon S3 suspends lifecycle actions until it marks the object's replication status as `COMPLETED`. If replication status is `FAILED`, S3 Lifecycle continues to block expiration and transition actions on the object until you resolve the underlying replication issue. For more information, see S3 Lifecycle and S3 Replication.

Replication status if replicating to multiple destination buckets

When you replicate objects to multiple destination buckets, the `x-amz-replication-status` header acts differently. The header of the source object returns a value of `COMPLETED` only when replication is successful to all destinations. The header remains at the `PENDING` value until replication has completed for all destinations. If one or more destinations fail replication, the header returns `FAILED`.

Replication status if Amazon S3 replica modification sync is enabled

When your replication rules enable Amazon S3 replica modification sync, replicas can report statuses other than `REPLICA`. If metadata changes are in the process of replicating, the `x-amz-replication-status` header returns `PENDING`. If replica modification sync fails to replicate metadata, the header returns `FAILED`. If metadata is replicated correctly, the replicas return the header `REPLICA`.

Using replication status information with Batch Replication jobs

When creating a Batch Replication job, you can optionally specify additional filters, such as the object creation date and replication status, to reduce the scope of the job.

You can filter objects to replicate based on the `ObjectReplicationStatuses` value, by providing one or more of the following values:

- `"NONE"` – Indicates that Amazon S3 has never attempted to replicate the object before.
- `"FAILED"` – Indicates that Amazon S3 has attempted, but failed, to replicate the object before.
- `"COMPLETED"` – Indicates that Amazon S3 has successfully replicated the object before.
- `"REPLICA"` – Indicates that this is a replica object that Amazon S3 has replicated from another source.

For more information about using these replication status values with Batch Replication, see the section called “Filters for a Batch Replication job”.

Finding replication status

To get the replication status of the objects in a bucket, you can use the Amazon S3 Inventory tool. Amazon S3 sends a CSV file to the destination bucket that you specify in the inventory configuration. You can also use Amazon Athena to query the replication status in the inventory report. For more information about Amazon S3 Inventory, see Cataloging and analyzing your data with S3 Inventory.

You can also find the object replication status by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the AWS SDK.

Using the S3 console

In the Amazon S3 console, you can view the replication status for an object on the object's details page.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **General purpose buckets** list, choose the name of the replication source bucket.
4. In the **Objects** list, choose the object name. The object's details page appears.
5. On the **Properties** tab, scroll down to the **Object management overview** section. Under **Management configurations**, see the value under **Replication status**.

Using the AWS CLI

Use the AWS Command Line Interface (AWS CLI) `head-object` command to retrieve object metadata, as shown in the following example. Replace the *amzn-s3-demo-source-bucket1* with the name of your replication source bucket, and replace the other *user input placeholders* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-source-bucket1 --key object-key --version-id object-version-id
```

The command returns object metadata, including the `ReplicationStatus` as shown in the following example response.

```
{
   "AcceptRanges":"bytes",
   "ContentType":"image/jpeg",
   "LastModified":"Mon, 23 Mar 2015 21:02:29 GMT",
   "ContentLength":3191,
   "ReplicationStatus":"COMPLETED",
   "VersionId":"jfnW.HIMOfYiD_9rGbSkmroXsFj3fqZ.",
   "ETag":"\"6805f2cfc46c0f04559748bb039d69ae\"",
   "Metadata":{

   }
}
```

Using the AWS SDKs

The following code fragments get your replication status by using the AWS SDK for Java and AWS SDK for .NET, respectively.

Java

```
GetObjectMetadataRequest metadataRequest = new GetObjectMetadataRequest(bucketName,
 key);
ObjectMetadata metadata = s3Client.getObjectMetadata(metadataRequest);

System.out.println("Replication Status : " +
 metadata.getRawMetadataValue(Headers.OBJECT_REPLICATION_STATUS));
```

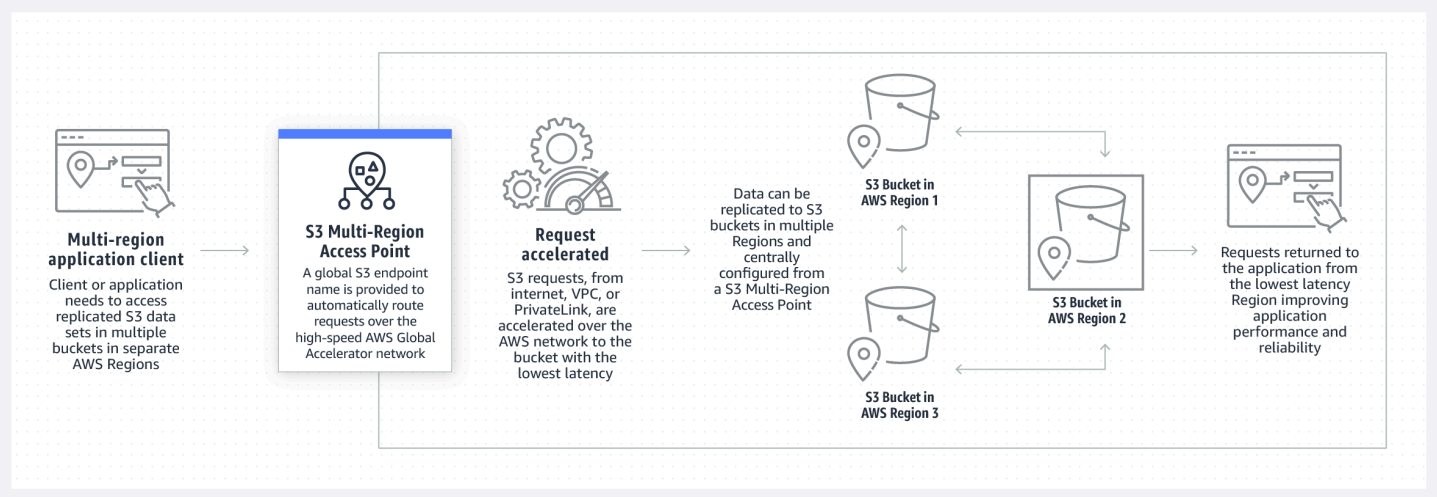
.NET

```
GetObjectMetadataRequest getmetadataRequest = new GetObjectMetadataRequest
    {
         BucketName = sourceBucket,
         Key        = objectKey
    };

GetObjectMetadataResponse getmetadataResponse =
 client.GetObjectMetadata(getmetadataRequest);
Console.WriteLine("Object replication status: {0}",
 getmetadataResponse.ReplicationStatus);
```

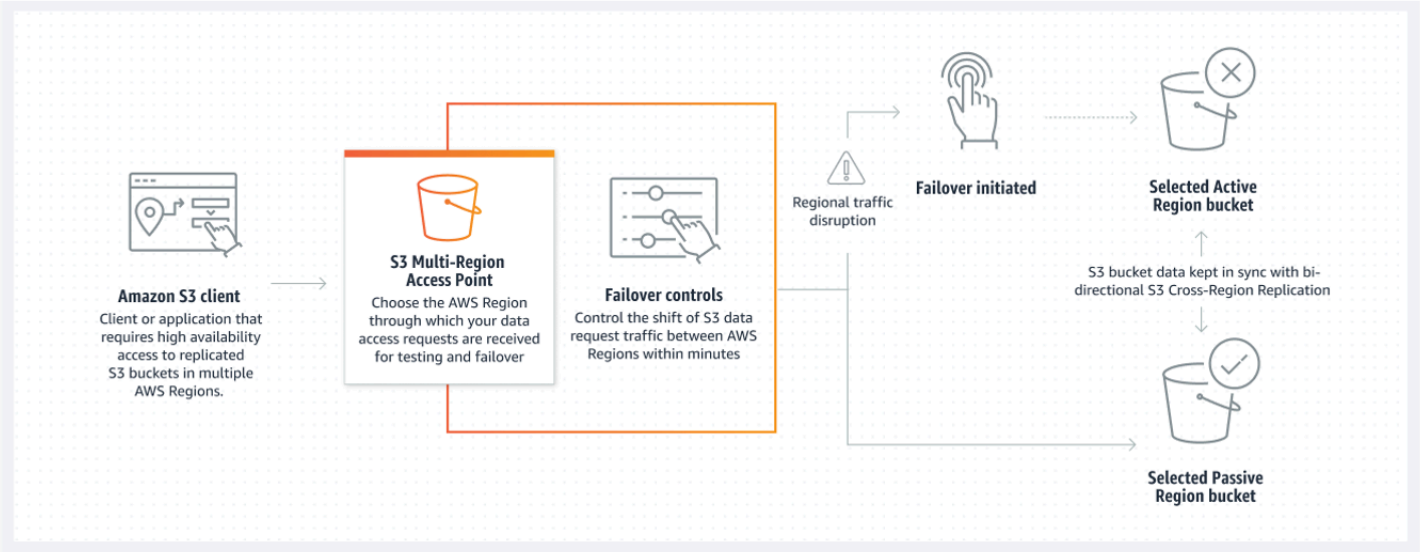
You can find the replication status of annotations by using the Amazon S3 API or Amazon S3 Metadata. The `ListObjectAnnotations` and `GetObjectAnnotation` API operations return the replication status for each annotation in the response. If you have an Amazon S3 Metadata table configuration that includes annotations, you can query the `replication_status` column in the annotation table. For more information, see the section called “Annotation table schema”.

Managing multi-Region traffic with Multi-Region Access Points



Amazon S3 Multi-Region Access Points provides a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provides built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint uses AWS Global Accelerator to automatically route over the AWS global network to the closest proximity S3 bucket with an active routing status.

If a Regional traffic disruption occurs, you can use Multi-Region Access Points failover controls to shift the S3 data request traffic between AWS Regions and redirect S3 traffic away from the disruptions within minutes. You can also test the application resiliency against a disruption to conduct application failover and perform disaster recovery simulations. If you need to connect and accelerate requests to S3 from outside of a VPC, you can simplify applications and network architecture with Amazon S3 Multi-Region Access Points. Your Multi-Region Access Points requests will be routed over the AWS global network and then back to S3 within the AWS Region, without having to traverse the public internet. As a result, you can build more highly available applications.



During your Multi-Region Access Points creation and setup, you'll specify a set of AWS Regions where you want to store data to be served through that Multi-Region Access Point. You can use the provided Multi-Region Access Points endpoint name to connect your clients. After you've established your client connections, you can select the existing or new buckets that you'd like to route the Multi-Region Access Points requests between. Then, use S3 Cross-Region Replication (CRR) rules to synchronize data among buckets in those Regions.

After you've set up your Multi-Region Access Point. you can then request or write data through the Multi-Region Access Points global endpoint. Amazon S3 automatically serves requests to the replicated data set from the closest available Region. Within the AWS Management Console, you're also able to view the underlying replication topology and replication metrics related to your Multi-Region Access Points requests. This gives you an even easier way to build, manage, and monitor storage for multi-Region applications. Alternatively, you can use Amazon CloudFront to automate the creation and configuration of S3 Multi-Region Access Points.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-active configuration. The graphic shows how Amazon S3 requests are automatically routed to buckets in the closest active AWS Region.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-passive configuration. The graphic shows how you can control Amazon S3 data-access traffic to fail over between active and passive AWS Regions.

Topics

- Creating Multi-Region Access Points
- Configuring a Multi-Region Access Point for use with AWS PrivateLink
- Making requests through a Multi-Region Access Point

Creating Multi-Region Access Points

To create a Multi-Region Access Point in Amazon S3, you do the following:

- Specify the name for the Multi-Region Access Point.
- Choose one bucket in each AWS Region that you want to serve requests for the Multi-Region Access Point.
- Configure the Amazon S3 Block Public Access settings for the Multi-Region Access Point.

You provide all of this information in a create request, which Amazon S3 processes asynchronously. Amazon S3 provides a token that you can use to monitor the status of the asynchronous creation request.

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide actionable recommendations to help you author policies that

are functional and conform to security best practices. To learn more about validating policies using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

When you use the API, the request to create a Multi-Region Access Point is asynchronous. When you submit a request to create a Multi-Region Access Point, Amazon S3 synchronously authorizes the request. It then immediately returns a token that you can use to track the progress of the creation request. For more information about tracking asynchronous requests to create and manage Multi-Region Access Points, see Using Multi-Region Access Points with supported API operations.

After you create the Multi-Region Access Point, you can create an access control policy for it. Each Multi-Region Access Point can have an associated policy. A Multi-Region Access Point policy is a resource-based policy that you can use to limit the use of the Multi-Region Access Point by resource, user, or other conditions.

Note

For an application or user to be able to access an object through a Multi-Region Access Point, both of the following policies must permit the request:

- The access policy for the Multi-Region Access Point
- The access policy for the underlying bucket that contains the object

When the two policies are different, the more restrictive policy takes precedence. To simplify permissions management for Multi-Region Access Points, you can delegate access control from the bucket to the Multi-Region Access Point. For more information, see the section called “Multi-Region Access Point policy examples”.

Using a bucket with a Multi-Region Access Point doesn't change the bucket's behavior when the bucket is accessed through the existing bucket name or an Amazon Resource Name (ARN). All existing operations against the bucket continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests that are made through the Multi-Region Access Point.

You can update the policy for a Multi-Region Access Point after creating it, but you can't delete the policy. However, you can update the Multi-Region Access Point policy to deny all permissions.

Topics

- Rules for naming Amazon S3 Multi-Region Access Points
- Rules for choosing buckets for Amazon S3 Multi-Region Access Points
- Create an Amazon S3 Multi-Region Access Point

- Deleting a Multi-Region Access Point

Rules for naming Amazon S3 Multi-Region Access Points

When you create a Multi-Region Access Point, you give it a name, which is a string that you choose. You can't change the name of the Multi-Region Access Point after it is created. The name must be unique in your AWS account, and it must conform to the naming requirements listed in Multi-Region Access Point restrictions and limitations. To help you identify the Multi-Region Access Point, use a name that is meaningful to you, to your organization, or that reflects the scenario.

You use this name when invoking Multi-Region Access Point management operations, such as `GetMultiRegionAccessPoint` and `PutMultiRegionAccessPointPolicy`. The name is not used to send requests to the Multi-Region Access Point, and it doesn't need to be exposed to clients who make requests by using the Multi-Region Access Point.

When Amazon S3 creates a Multi-Region Access Point, it automatically assigns an alias to it. This alias is a unique alphanumeric string that ends in `.mrap`. The alias is used to construct the hostname and the Amazon Resource Name (ARN) for a Multi-Region Access Point. The fully qualified name is also based on the alias for the Multi-Region Access Point.

You can't determine the name of a Multi-Region Access Point from its alias, so you can disclose an alias without risk of exposing the name, purpose, or owner of the Multi-Region Access Point. Amazon S3 selects the alias for each new Multi-Region Access Point, and the alias can't be changed. For more information about addressing a Multi-Region Access Point, see Making requests through a Multi-Region Access Point.

Multi-Region Access Point aliases are unique throughout time and aren't based on the name or configuration of a Multi-Region Access Point. If you create a Multi-Region Access Point, and then

delete it and create another one with the same name and configuration, the second Multi-Region Access Point will have a different alias than the first. New Multi-Region Access Points can never have the same alias as a previous Multi-Region Access Point.

Rules for choosing buckets for Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point is associated with the Regions where you want to fulfill requests. The Multi-Region Access Point must be associated with exactly one bucket in each of those Regions. You specify the name of each bucket in the request to create the Multi-Region Access Point. Buckets that support the Multi-Region Access Point can either be in the same AWS account that owns the Multi-Region Access Point, or they can be in other AWS accounts.

A single bucket can be used by multiple Multi-Region Access Points.

Important

- You can specify the buckets that are associated with a Multi-Region Access Point only at the time that you create it. After it is created, you can’t add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one.
- You can't delete a bucket that is part of a Multi-Region Access Point. If you want to delete a bucket that's attached to a Multi-Region Access Point, delete the Multi-Region Access Point first.
- If you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see Multi-Region Access Point policy examples.
- Not all Regions support Multi-Region Access Points. To see the list of supported Regions, see Multi-Region Access Point restrictions and limitations.

You can create replication rules to synchronize data between buckets. These rules enable you to automatically copy data from source buckets to destination buckets. Having buckets connected to a Multi-Region Access Point does not affect how replication works. Configuring replication with Multi-Region Access Points is described in a later section.

Important

When you make a request to a Multi-Region Access Point, the Multi-Region Access Point isn't aware of the data contents of the buckets in the Multi-Region Access Point. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, we recommend that you configure S3 Cross-Region Replication (CRR). For more information, see Configuring replication for use with Multi-Region Access Points.

Create an Amazon S3 Multi-Region Access Point

The following example demonstrates how to create a Multi-Region Access Point by using the Amazon S3 console.

Using the S3 console

To create a Multi-Region Access Point

Note

Multi-Region Access Point opt-in Regions aren't currently supported in the Amazon S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose **Create Multi-Region Access Points** to begin creating your Multi-Region Access Point.
4. On the **Multi-Region Access Point** page, supply a name for the Multi-Region Access Point in the **Multi-Region Access Point name** field.
5. Select the buckets that will be associated with this Multi-Region Access Point. You can choose buckets that are in your account, or you can choose buckets from other accounts.

   Note

   You must add at least one bucket from either your account or other accounts. Also, be aware that Multi-Region Access Points support only one bucket per AWS Region.

Therefore, you can't add two buckets from the same Region. AWS Regions that are disabled by default are not supported.

- To add a bucket that is in your account, choose **Add buckets**. A list of all the buckets in your account displays. You can search for your bucket by name, or sort the bucket names in alphabetical order.
- To add a bucket from another account, choose **Add bucket from other accounts**. Make sure that you know the exact bucket name and AWS account ID because you can't search or browse for buckets in other accounts.

> **Note**
>
> You must enter a valid AWS account ID and bucket name. The bucket must also be in a supported Region, or you will encounter an error when you try to create your Multi-Region Access Point. For the list of Regions that support Multi-Region Access Points, see Multi-Region Access Points restrictions and limitations.

6. (Optional) If you need to remove a bucket that you added, choose **Remove**.

> **Note**
>
> You can't add or remove buckets to this Multi-Region Access Point after you've finished creating it.

7. Under **Block Public Access settings for this Multi-Region Access Point**, select the Block Public Access settings that you want to apply to the Multi-Region Access Point. By default, all Block Public Access settings are enabled for new Multi-Region Access Points. We recommend that you leave all settings enabled unless you know that you have a specific need to disable any of them.

> **Note**
>
> You can't change the Block Public Access settings for a Multi-Region Access Point after the Multi-Region Access Point has been created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

8. Choose **Create Multi-Region Access Point**.

> **Important**
>
> When you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see Multi-Region Access Point policy examples.

Using the AWS CLI

You can use the AWS CLI to create a Multi-Region Access Point. When you create the Multi-Region Access Point, you must provide all the buckets that it will support. You can't add buckets to the Multi-Region Access Point after it has been created.

The following example creates a Multi-Region Access Point with two buckets by using the AWS CLI. To use this example command, replace the *`user input placeholders`* with your own information.

> **Note**
>
> To create a Multi-Region Access Point using buckets in an opt-in Region, make sure to enable all opt-in Regions first. Otherwise, you'll get a `403 InvalidRegion` error when you try to create a Multi-Region Access Point using buckets for an opt-in Region that you haven't actually opted in to.

```
aws s3control create-multi-region-access-point --account-id 111122223333 --details '{
        "Name": "simple-multiregionaccesspoint-with-two-regions",
        "PublicAccessBlock": {
            "BlockPublicAcls": true,
            "IgnorePublicAcls": true,
            "BlockPublicPolicy": true,
            "RestrictPublicBuckets": true
        },
        "Regions": [
            { "Bucket": "amzn-s3-demo-bucket1" },
```

```
            { "Bucket": "amzn-s3-demo-bucket2" }
        ]
    }' --region us-west-2
```

Blocking public access with Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point has distinct settings for Amazon S3 Block Public Access. These settings operate in conjunction with the Block Public Access settings for the AWS account that owns the Multi-Region Access Point and the underlying buckets.

When Amazon S3 authorizes a request, it applies the most restrictive combination of these settings. If the Block Public Access settings for any of these resources (the Multi-Region Access Point owner account, the underlying bucket, or the bucket owner account) block access for the requested action or resource, Amazon S3 rejects the request.

We recommend that you enable all Block Public Access settings unless you have a specific need to disable any of them. By default, all Block Public Access settings are enabled for a Multi-Region Access Point. If Block Public Access is enabled, the Multi-Region Access Point can't accept internet-based requests.

> **Important**
>
> You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

For more information about Amazon S3 Block Public Access, see Blocking public access to your Amazon S3 storage.

Viewing Amazon S3 Multi-Region Access Points configuration details

The following example demonstrates how to view Multi-Region Access Point configuration details by using the Amazon S3 console.

Using the S3 console

To create a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.

3. Choose the name of the Multi-Region Access Point for which you want to view the configuration details.

   - The **Properties** tab lists all of the buckets that are associated with your Multi-Region Access Point, the creation date, the Amazon Resource Name (ARN), and the alias. The AWS account ID column also lists any buckets owned by external accounts that are associated with your Multi-Region Access Point.
   - The **Permissions** tab lists the Block Public Access settings that are applied to the buckets associated with this Multi-Region Access Point. You can also view the Multi-Region Access Point policy for your Multi-Region Access Point, if you've created one. The **Info** alert on the **Permissions** page also lists all the buckets (in your account and other accounts) for this Multi-Region Access Point that have the **Public Access is blocked** setting enabled.
   - The **Replication and failover** tab provides a map view of the buckets that are associated with your Multi-Region Access Point and the Regions that the buckets reside int. If there are buckets from another account that you don't have permission to pull data from, the Region will be marked in red on the **Replication summary** map, indicating that it is an **AWS Region with errors getting replication status**.

     > **Note**
     >
     > To retrieve replication status information from a bucket in an external account, the bucket owner must grant you the `s3:GetBucketReplication` permission in their bucket policy.

     This tab also provides the replication metrics, replication rules, and failover statuses for the Regions that are used with your Multi-Region Access Point.

Using the AWS CLI

You can use the AWS CLI to view the configuration details for a Multi-Region Access Point.

The following AWS CLI example gets your current Multi-Region Access Point configuration. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control get-multi-region-access-point --account-id 111122223333 --name amzn-s3-demo-bucket
```

Deleting a Multi-Region Access Point

The following procedure explains how to delete a Multi-Region Access Point by using the Amazon S3 console. Be aware that deleting a Multi-Region Access Point doesn't delete the buckets associated with the Multi-Region Access Point. Instead, it only deletes the Multi-Region Access Point itself.

> **Note**
>
> S3 Multi-Region Access Points using buckets in AWS opt-in Regions is currently only supported through AWS SDKs and the AWS CLI. To delete a Multi-Region Access Point using buckets in an opt-in Region, make sure to specify which AWS opt-in Regions your account can use first. Otherwise, if you try to delete a Multi-Region Access Point that uses buckets in disabled AWS opt-in Regions, you'll receive an error.

Using the S3 console

To delete a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Select the option button next to the name of your Multi-Region Access Point.
4. Choose **Delete**.
5. In the **Delete Multi-Region Access Point** dialog box, enter the name of the AWS bucket that you want to delete.

   > **Note**
   >
   > Make sure to enter a valid bucket name. Otherwise, the **Delete** button will be disabled.

6. Choose **Delete** to confirm deletion of your Multi-Region Access Point.

Using the AWS CLI

You can use the AWS CLI to delete a Multi-Region Access Point. This action does not delete the buckets associated with the Multi-Region Access Point, only the Multi-Region Access Point itself. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-multi-region-access-point --account-id 123456789012 --details
 Name=example-multi-region-access-point-name
```

Configuring a Multi-Region Access Point for use with AWS PrivateLink

You can use Multi-Region Access Points to route Amazon S3 request traffic between AWS Regions. Each Multi-Region Access Point global endpoint routes Amazon S3 data request traffic from multiple sources without your having to build complex networking configurations with separate endpoints. These data-request traffic sources include:

- Traffic originating in a virtual private cloud (VPC)
- Traffic from on-premises data centers traveling over AWS PrivateLink
- Traffic from the public internet

If you establish an AWS PrivateLink connection to an S3 Multi-Region Access Point, you can route S3 requests into AWS, or across multiple AWS Regions, over a private connection by using a simple network architecture and configuration. When you use AWS PrivateLink, you don't need to configure a VPC peering connection.

Topics

- Configuring Multi-Region Access Point opt-in Regions
- Configuring a Multi-Region Access Point for use with AWS PrivateLink
- Removing access to a Multi-Region Access Point from a VPC endpoint

Configuring Multi-Region Access Point opt-in Regions

An AWS opt-in Region is a Region that isn't enabled by default in your AWS account. In contrast, Regions that are enabled by default are known as AWS Regions or commercial Regions.

To start using Multi-Region Access Points in AWS opt-in Regions, you must manually enable the opt-in Region for your AWS account before creating your Multi-Region Access Point. After you

enable the opt-in Region, you can create Multi-Region Access Points with buckets in the selected opt-in Region. For instructions on how to enable or disable an opt-in Region for your AWS account or AWS Organization, see Enable or disable a Region for standalone accounts or Enable or disable a Region in your organization.

> **Note**
>
> Multi-Region Access Point opt-in Regions are currently only supported through AWS SDKs and AWS CLI.

S3 Multi-Region Access Points supports the following AWS opt-in Regions:

- `Africa (Cape Town)`
- `Asia Pacific (Hong Kong)`
- `Asia Pacific (Jakarta)`
- `Asia Pacific (Melbourne)`
- `Asia Pacific (Hyderabad)`
- `Canada West (Calgary)`
- `Europe (Zurich)`
- `Europe (Milan)`
- `Europe (Spain)`
- `Israel (Tel Aviv)`
- `Middle East (Bahrain)`
- `Middle East (UAE)`

> **Note**
>
> There are no additional costs for enabling an opt-in Region. However, creating or using a resource in a Multi-Region Access Point results in billing charges.

Using a Multi-Region Access Point in an AWS opt-in Region

To perform a data plane operation on your Multi-Region Access Point, all associated AWS accounts must enable the opt-in Regions that are part of the Multi-Region Access Point. This requirement applies to the requester account, the Multi-Region Access Point owner, S3 bucket owners, and the VPC endpoint owner. If any of these accounts don't enable AWS opt-in Regions, the Multi-Region Access Point requests fail. For more information about the `InvalidToken` or `AllAccessDisabled` errors, see List of error codes.

> **Note**
>
> Control plane operations such as updating your Multi-Region Access Point policy or updating your failover configuration aren't impacted by the opt-in Region status of any Region that is part of your Multi-Region Access Point. You also don't need to disable any active opt-in Regions before deleting a Multi-Region Access Point.

Disabling an active AWS opt-in Region

If you disable opt-in Region that is part of your Multi-Region Access Point, requests routed to this Region result in a `403 AllAccessDisabled` error. To safely disable an opt-in Region, we recommend that you first identify an alternate Region in your Multi-Region Access Point configuration to route the traffic to. You can then use Multi-Region Access Point failover controls to mark the alternate Region as active, and mark the Region to be disabled as passive. After changing the failover controls, you can disable the Region you want to opt out of.

Enabling a previously disabled AWS opt-in Region

To enable an opt-in AWS Region that was previously disabled for your Multi-Region Access Point, make sure to update your AWS account settings. After you re-enable the opt-in Region, run the PutMultiRegionAccessPointPolicy API operation to apply the Multi-Region Access Points policy to the opt-in Region.

If your Multi-Region Access Point is accessed through a VPC endpoint, we recommend that you update your VPCE policy and use the ModifyVpcEndpoint API operation to apply the updated VPC endpoint policy to the re-enabled opt-in Region.

Multi-Region Access Points policy and multiple AWS accounts

If your Multi-Region Access Points policy grants access to multiple AWS accounts, all requester accounts must also enable the same opt-in Regions in their account settings. If the requester account submits a Multi-Region Access Point request without enabling the opt-in Regions that are part of the Multi-Region Access Point, it'll result in a `400 InvalidToken` error.

AWS opt-in Region considerations

When you access a Multi-Region Access Point from an opt-in Region, be aware of the following:

- When you enable an opt-in Region, it allows you to create a Multi-Region Access Point using the buckets from the opt-in Region. When you disable an opt-in Region, the Multi-Region Access Point is no longer supported in the opt-in Region. If you no longer want an opt-in Region enabled for your Multi-Region Access Point, make sure to disable the Region for your account first. Then, create a new Multi-Region Access Point with your preferred list of opt-in Regions.
- If you attempt to create your Multi-Region Access Point with a disabled opt-in Region, you'll receive a `403 InvalidRegion` error. After you enable the opt-in Region, try creating the Multi-Region Access Point again.
- The maximum number of supported Regions for a Multi-Region Access Point is 17 Regions. This includes both opt-in Regions and commercial Regions. For more information, see Multi-Region Access Points restrictions and limitations.
- Control plane requests for Multi-Region Access Points will work, even if you haven't opted in to any Regions.
- When you're trying to create a Multi-Region Access Point for the first time, you must opt into all Regions that are part of the Multi-Region Access Point.
- Any AWS accounts that are granted access to an S3 Multi-Region Access Point through the Multi-Region Access Point policy must also enable the same opt-in Regions that are part of the Multi-Region Access Point.

Configuring a Multi-Region Access Point for use with AWS PrivateLink

AWS PrivateLink provides you with private connectivity to Amazon S3 using private IP addresses in your virtual private cloud (VPC). You can provision one or more interface endpoints inside your VPC to connect to Amazon S3 Multi-Region Access Points.

You can create **com.amazonaws.s3-global.accesspoint** endpoints for Multi-Region Access Points through the AWS Management Console, AWS CLI, or AWS SDKs. To learn more about how to

configure an interface endpoint for Multi-Region Access Point, see Interface VPC endpoints in the *VPC User Guide*.

To make requests to a Multi-Region Access Point through interface endpoints, follow these steps to configure the VPC and the Multi-Region Access Point.

To configure a Multi-Region Access Point to use with AWS PrivateLink

1. Create or have an appropriate VPC endpoint that can connect to Multi-Region Access Points. For more information about creating VPC endpoints, see Interface VPC endpoints in the *VPC User Guide*.

   > **Important**
   >
   > Make sure to create a **com.amazonaws.s3-global.accesspoint** endpoint. Other endpoint types cannot access Multi-Region Access Points.

   After this VPC endpoint is created, all Multi-Region Access Point requests in the VPC route through this endpoint if you have private DNS enabled for the endpoint. This is enabled by default.
2. If the Multi-Region Access Point policy does not support connections from VPC endpoints, you will need to update it.
3. Verify that the individual bucket policies will allow access to the users of the Multi-Region Access Point.

Remember that Multi-Region Access Points work by routing requests to buckets, not by fulfilling requests themselves. This is important to remember because the originator of the request must have permissions to the Multi-Region Access Point and be allowed to access the individual buckets in the Multi-Region Access Point. Otherwise, the request might be routed to a bucket where the originator doesn't have permissions to fulfill the request. A Multi-Region Access Point and the buckets associated can be owned by the same or another AWS account. However, VPCs from different accounts can use a Multi-Region Access Point if the permissions are configured correctly.

Because of this, the VPC endpoint policy must allow access both to the Multi-Region Access Point and to each underlying bucket that you want to be able to fulfill requests.

As mentioned previously, you also must make sure that the Multi-Region Access Point policy is configured to support access through a VPC endpoint. You don't need to specify the VPC endpoint that is requesting access. The following sample policy would grant access to any requester trying to use the Multi-Region Access Point for the `GetObject` requests.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
    {
        "Sid": "Open-read-MRAP-policy",
        "Effect": "Allow",
        "Principal": "*",
        "Action": [
            "s3:GetObject"
          ],
        "Resource": "arn:aws:s3::111122223333:accesspoint/mfzwi23gnjvgw.mrap/
object/*"
    }]
}
```

And of course, the individual buckets would each need a policy to support access from requests submitted through VPC endpoint. The following example policy grants read access to any anonymous users. This would include requests made through the VPC endpoint.

JSON

```
{
    "Version":"2012-10-17",
   "Statement": [
   {
       "Sid": "Public-read",
       "Effect": "Allow",
       "Principal": "*",
       "Action": "s3:GetObject",
       "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket1",
           "arn:aws:s3:::amzn-s3-demo-bucket2/*"]
    }]
```

```
}
```

For more information about editing a VPC endpoint policy, see Control access to services with VPC endpoints in the *VPC User Guide*.

Removing access to a Multi-Region Access Point from a VPC endpoint

If you own a Multi-Region Access Point and want to remove access to it from an interface endpoint, you must supply a new access policy for the Multi-Region Access Point that prevents access for requests coming through VPC endpoints. However, if the buckets in your Multi-Region Access Point support requests through VPC endpoints, they will continue to support these requests. If you want to prevent that support, you must also update the policies for the buckets. Supplying a new access policy to the Multi-Region Access Point prevents access only to the Multi-Region Access Point, not to the underlying buckets.

> **Note**
>
> You can't delete an access policy for a Multi-Region Access Point. To remove access to a Multi-Region Access Point, you must provide a new access policy with the modified access that you want.

Instead of updating the access policy for the Multi-Region Access Point, you can update the bucket policies to prevent requests through VPC endpoints. In this case, users can still access the Multi-Region Access Point through the VPC endpoint. However, if the Multi-Region Access Point request is routed to a bucket where the bucket policy prevents access, the request will generate an error message.

Making requests through a Multi-Region Access Point

Like other resources, Amazon S3 Multi-Region Access Points have Amazon Resource Names (ARNs). You can use these ARNs to direct requests to Multi-Region Access Points by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 API. You can also use these ARNs to identify Multi-Region Access Points in access control policies. A Multi-Region Access Point ARN doesn't include or disclose the name of the Multi-Region Access Point. For more information about ARNs, see Amazon Resource Names (ARNs) in the *AWS General Reference*.

> **Note**
>
> The Multi-Region Access Point alias and ARN cannot be used interchangeably.

Multi-Region Access Point ARNs use the following format:

`arn:aws:s3::account-id:accesspoint/MultiRegionAccessPoint_alias`

The following are a few examples of Multi-Region Access Point ARNs:

- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap` represents the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by AWS account `123456789012`.
- `arn:aws:s3::123456789012:accesspoint/*` represents all Multi-Region Access Points under the account `123456789012`. This ARN matches all Multi-Region Access Points for account `123456789012`, but doesn't match any Regional Amazon S3 Access Points because the ARN doesn't include an AWS Region. In contrast, the ARN `arn:aws:s3:us-west-2:123456789012:accesspoint/*` matches all Regional Amazon S3 Access Points in the Region `us-west-2` for the account `123456789012`, but doesn't match any Multi-Region Access Points.

ARNs for objects that are accessed through a Multi-Region Access Point use the following format:

`arn:aws:s3::account_id:accesspoint/MultiRegionAccessPoint_alias//key`

As with Multi-Region Access Point ARNs, the ARNs for objects that are accessed through Multi-Region Access Points don't include an AWS Region. Here are some examples.

- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01` represents the object with key `-01`, which is accessed through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by account `123456789012`.
- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap//*` represents all objects that can be accessed through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, in account `123456789012`.
- `arn:aws:s3::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01/finance/*` represents all objects that can be accessed under the `-01/finance/` for the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, in account `123456789012`.

Multi-Region Access Point hostnames

You can access data in Amazon S3 through a Multi-Region Access Point by using the hostname of the Multi-Region Access Point. Requests can be directed to this hostname from the public internet. If you have configured one or more internet gateways for the Multi-Region Access Point, requests can also be directed to this hostname from a virtual private cloud (VPC). For more information about creating VPC interface endpoints to use with Multi-Region Access Points, see Configuring a Multi-Region Access Point for use with AWS PrivateLink.

To make requests through a Multi-Region Access Point from a VPC by using a VPC endpoint, you can use AWS PrivateLink. When you're making requests to a Multi-Region Access Point by using AWS PrivateLink, you cannot directly use an endpoint-specific Regional DOMAIN NAME SYSTEM (DNS) name that ends with *region*`.vpce.amazonaws.com`. This hostname will not have a certificate associated with it, so it cannot be used directly. You can still use the public DOMAIN NAME SYSTEM (DNS) name of the VPC endpoint as a `CNAME` or `ALIAS` target. Alternatively, you can enable private DOMAIN NAME SYSTEM (DNS) on the endpoint and use the standard Multi-Region Access Point *MultiRegionAccessPoint_alias*`.accesspoint.s3-global.amazonaws.com` DOMAIN NAME SYSTEM (DNS) name, as described in this section.

When you make requests to the API for Amazon S3 data operations (for example, `GetObject`) through a Multi-Region Access Point, the hostname for the request is as follows:

MultiRegionAccessPoint_alias`.accesspoint.s3-global.amazonaws.com`

For example, to make a `GetObject` request through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, make a request to the hostname `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. The `s3-global` portion of the hostname indicates that this hostname is not for a specific Region.

Making requests through a Multi-Region Access Point is similar to making requests through a single-Region access point. However, it's important to be aware of the following differences:

- Multi-Region Access Point ARNs don't include an AWS Region. They follow the format `arn:aws:s3::`*account-id*`:accesspoint/`*MultiRegionAccessPoint_alias*.
- For requests made through API operations (these requests don't require the use of an ARN), Multi-Region Access Points use a different endpoint scheme. The scheme is *MultiRegionAccessPoint_alias*`.accesspoint.s3-global.amazonaws.com`—for example, `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. Note the differences compared to a single-Region access point:

- Multi-Region Access Point hostnames use their alias, not the Multi-Region Access Point name.
- Multi-Region Access Point hostnames don't include the owner's AWS account ID.
- Multi-Region Access Point hostnames don't include an AWS Region.
- Multi-Region Access Point hostnames include `s3-global.amazonaws.com` instead of `s3.amazonaws.com`.

- Multi-Region Access Point requests must be signed by using Signature Version 4A (SigV4A). When you use the AWS SDKs, the SDK automatically converts a SigV4 to SigV4A. Therefore, make sure that your AWS SDK supports SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about SigV4A, see Signing AWS API requests in the *AWS General Reference*.

Multi-Region Access Points and Amazon S3 Transfer Acceleration

Amazon S3 Transfer Acceleration is a feature that enables fast transfer of data to buckets. Transfer Acceleration is configured on the individual bucket level. For more information about Transfer Acceleration, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

Multi-Region Access Points use a similar accelerated transfer mechanism as Transfer Acceleration for sending large objects over the AWS network. Because of this, you don't need to use Transfer Acceleration when sending requests through a Multi-Region Access Point. This increased transfer performance is automatically incorporated into the Multi-Region Access Point.

Topics

- Permissions
- Multi-Region Access Point restrictions and limitations
- Multi-Region Access Point request routing
- Amazon S3 Multi-Region Access Points failover controls
- Configuring replication for use with Multi-Region Access Points
- Using Multi-Region Access Points with supported API operations
- Monitoring and logging requests made through a Multi-Region Access Point to underlying resources

Permissions

Amazon S3 Multi-Region Access Points can simplify data access for Amazon S3 buckets in multiple AWS Regions. Multi-Region Access Points are named global endpoints that you can use to perform Amazon S3 data-access object operations, such as `GetObject` and `PutObject`. Each Multi-Region Access Point can have distinct permissions and network controls for any request that is made through the global endpoint.

Each Multi-Region Access Point can also enforce a customized access policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For a cross-account request to succeed, the following policies must permit the operation:

- The Multi-Region Access Point policy
- The underlying AWS Identity and Access Management (IAM) policy
- The underlying bucket policy (where the request is routed to)

> **Note**
>
> For same account requests, only the underlying IAM policy, which grants the appropriate access, is required.

You can configure any Multi-Region Access Point policy to accept requests only from specific IAM users or groups. For an example of how to do this, see Example 2 in the section called "Multi-Region Access Point policy examples". To restrict Amazon S3 data access to a private network, you can configure the Multi-Region Access Point policy to accept requests only from a virtual private cloud (VPC).

For example, suppose that you make a `GetObject` request through a Multi-Region Access Point by using a user called `AppDataReader` in your AWS account. To help ensure that the request won't be denied, the `AppDataReader` user must be granted the `s3:GetObject` permission by the Multi-Region Access Point and by each bucket underlying the Multi-Region Access Point. `AppDataReader` won't be able to retrieve data from any bucket that doesn't grant this permission.

> **Important**
>
> Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name

or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

Managing public access to a Multi-Region Access Point

Multi-Region Access Points support independent Block Public Access settings for each Multi-Region Access Point. When you create a Multi-Region Access Point, you can specify the Block Public Access settings that apply to that Multi-Region Access Point.

Note

Any Block Public Access settings that are enabled under **Block Public Access settings for this account** (in your own account) or **Block Public Settings for external buckets** still apply even if the independent Block Public Access settings for your Multi-Region Access Point are disabled.

For any request that is made through a Multi-Region Access Point, Amazon S3 evaluates the Block Public Access settings for:

- The Multi-Region Access Point
- The underlying buckets (including external buckets)
- The account that owns the Multi-Region Access Point
- The account that owns the underlying buckets (including external accounts)

If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request. For more information about the Amazon S3 Block Public Access feature, see Blocking public access to your Amazon S3 storage.

Important

By default, all Block Public Access settings are enabled for Multi-Region Access Points. You must explicitly turn off any settings that you don't want to apply to a Multi-Region Access Point.

You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

Viewing Block Public Access settings for a Multi-Region Access Point

To view the Block Public Access settings for a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to review.
4. Choose the **Permissions** tab.
5. Under **Block Public Access settings for this Multi-Region Access Point**, review the Block Public Access settings for your Multi-Region Access Point.

> **Note**
>
> You can't edit the Block Public Access settings after the Multi-Region Access Point is created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

Using a Multi-Region Access Point policy

The following example Multi-Region Access Point policy grants an IAM user access to list and download files from your Multi-Region Access Point. To use this example policy, replace the *`user input placeholders`* with your own information.

JSON

```
{
  "Version":"2012-10-17",
  "Statement":[
     {
        "Effect":"Allow",
```

```
         "Principal":{
            "AWS":"arn:aws:iam::123456789012:user/JohnDoe"
         },
         "Action":[
            "s3:ListBucket",
            "s3:GetObject"
         ],
         "Resource":[
            "arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias",
            "arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias/
object/*"
         ]
      }
   ]
}
```

To associate your Multi-Region Access Point policy with the specified Multi-Region Access Point by using the AWS Command Line Interface (AWS CLI), use the following `put-multi-region-access-point-policy` command. To use this example command, replace the *`user input placeholders`* with your own information. Each Multi-Region Access Point can have only one policy, so a request made to the `put-multi-region-access-point-policy` action replaces any existing policy that is associated with the specified Multi-Region Access Point.

AWS CLI

```
aws s3control put-multi-region-access-point-policy
--account-id 111122223333
--details { "Name": "amzn-s3-demo-bucket-MultiRegionAccessPoint",
 "Policy": "{ \"Version\": \"2012-10-17\", \"Statement\": { \"Effect\":
 \"Allow\", \"Principal\": { \"AWS\": \"arn:aws:iam::111122223333:root
\" }, \"Action\": [\"s3:ListBucket\", \"s3:GetObject\"], \"Resource\":
 [ \"arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias",
 \"arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/*
\" ] } }" }
```

To query your results for the previous operation, use the following command:

AWS CLI

```
aws s3control describe-multi-region-access-point-operation
```

```
--account-id 111122223333
--request-token-arn requestArn
```

To retrieve your Multi-Region Access Point policy, use the following command:

AWS CLI

```
aws s3control get-multi-region-access-point-policy
--account-id 111122223333
--name=amzn-s3-demo-bucket-MultiRegionAccessPoint
```

Editing the Multi-Region Access Point policy

The Multi-Region Access Point policy (written in JSON) provides storage access to the Amazon S3 buckets that are used with this Multi-Region Access Point. You can allow or deny specific principals to perform various actions on your Multi-Region Access Point. When a request is routed to a bucket through the Multi-Region Access Point, both the access policies for the Multi-Region Access Point and the bucket apply. The more restrictive access policy always takes precedence.

> **Note**
>
> If a bucket contains objects that are owned by other accounts, the Multi-Region Access Point policy doesn't apply to the objects that are owned by other AWS accounts.

After you apply a Multi-Region Access Point policy, the policy cannot be deleted. You can either edit the policy or create a new policy that overwrites the existing one.

To edit the Multi-Region Access Point policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to edit the policy for.
4. Choose the **Permissions** tab.
5. Scroll down to the **Multi-Region Access Point policy** section. Choose **Edit** to update the policy (in JSON).

6. The **Edit Multi-Region Access Point policy** page appears. You can either enter the policy directly into the text field, or you can choose **Add statement** to select policy elements from a dropdown list.

> **Note**
>
> The console automatically displays the Multi-Region Access Point Amazon Resource Name (ARN), which you can use in the policy. For example Multi-Region Access Point policies, see the section called “Multi-Region Access Point policy examples”.

Multi-Region Access Point policy examples

Amazon S3 Multi-Region Access Points support AWS Identity and Access Management (IAM) resource policies. You can use these policies to control the use of the Multi-Region Access Point by resource, user, or other conditions. For an application or user to be able to access objects through a Multi-Region Access Point, both the Multi-Region Access Point and the underlying bucket must allow the same access.

To allow the same access to both the Multi-Region Access Point and the underlying bucket, do one of the following:

- **(Recommended)** To simplify access controls when using an Amazon S3 Multi-Region Access Point, delegate access control for the Amazon S3 bucket to the Multi-Region Access Point. For an example of how to do this, see Example 1 in this section.
- Add the same permissions contained in the Multi-Region Access Point policy to the underlying bucket policy.

> **Important**
>
> Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

Example 1 – Delegating access to specific Multi-Region Access Points in your bucket policy (for the same account or cross-account)

The following example bucket policy grants full bucket access to a specific Multi-Region Access Point. This means that all access to this bucket is controlled by the policies that are attached to the Multi-Region Access Point. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket. You can use this bucket policy structure for Multi-Region Access Points in either the same account or in another account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement" : [
    {
        "Effect": "Allow",
        "Principal" : { "AWS": "*" },
        "Action" : "*",
        "Resource" : [ "arn:aws:s3:::amzn-s3-demo-bucket", "arn:aws:s3:::amzn-s3-
demo-bucket/*"],
        "Condition": {
            "StringEquals" : { "s3:DataAccessPointArn" :
 "arn:aws:s3::111122223333:accesspoint/example-multi-region-access-point" }
        }
    }]
}
```

> **Note**
>
> If there are multiple Multi-Region Access Points that you're granting access to, make sure to list each Multi-Region Access Point.

Example 2 – Granting an account access to a Multi-Region Access Point in your Multi-Region Access Point policy

The following Multi-Region Access Point policy allows account *123456789012* permission to list and read the objects contained in the Multi-Region Access Point defined by the *MultiRegionAccessPoint_ARN*.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
       "Effect": "Allow",
       "Principal": {
          "AWS": "arn:aws:iam::111122223333:user/JohnDoe"
       },
       "Action": [
          "s3:ListBucket",
          "s3:GetObject"
       ],
       "Resource": [
          "arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias",
          "arn:aws:s3::111122223333:accesspoint/MultiRegionAccessPoint_alias/
object/*"
       ]
     }
  ]
}
```

Example 3 – Multi-Region Access Point policy that allows bucket listing

The following Multi-Region Access Point policy allows account *123456789012* permission to list the objects contained in the Multi-Region Access Point defined by the *MultiRegionAccessPoint_ARN*.

Multi-Region Access Point restrictions and limitations

Multi-Region Access Points in Amazon S3 have the following restrictions and limitations.

Names and aliases

Multi-Region Access Point names must meet the following requirements:

- Must be unique within a single AWS account.
- Must begin with a number or lowercase letter.
- Must be between 3 and 50 characters long.

- Can't begin or end with a hyphen (-).
- Can't contain underscores (_), uppercase letters, or periods (.).
- Can't be edited after they are created.

Multi-Region Access Point aliases (which are different from a Multi-Region Access Point name), are automatically generated by Amazon S3 and can't be edited or reused. For more information about the difference between Multi-Region Access Point aliases and Multi-Region Access Point names and their respective naming rules, see Rules for naming Amazon S3 Multi-Region Access Points.

Accessing a Multi-Region Access Point

You can't access data through a Multi-Region Access Point by using gateway endpoints. However, you can access data through a Multi-Region Access Point by using interface endpoints. To use AWS PrivateLink, you must create VPC endpoints. For more information, see Configuring a Multi-Region Access Point for use with AWS PrivateLink. However, be aware that IPv6 isn't supported.

To use Multi-Region Access Points with Amazon CloudFront, you must configure the Multi-Region Access Point as a `Custom Origin` distribution type. For more information about various origin types, see Using various origins with CloudFront distributions. For more information about using Multi-Region Access Points with Amazon CloudFront, see Building an active-active, proximity-based application across multiple Regions on the *AWS Storage Blog*.

> **Note**
>
> S3 on Outposts buckets aren't supported.

Signing AWS API requests

To sign an AWS API request, your Multi-Region Access Point must meet the following minimum requirements:

> **Note**
>
> Multi-Region Access Points don't support anonymous requests.

- Support for Transport Layer Security (TLS) version 1.2.

- Support for Signature Version 4 (SigV4A)–This version of SigV4 allows requests to be signed for multiple AWS Regions. This feature is useful in API operations that might result in data access from one of several Regions. When using an AWS SDK, you supply your credentials, and the requests to Multi-Region Access Points will use Signature Version 4A without additional configuration. Make sure to check your AWS SDK compatibility with the SigV4A algorithm. For more information about SigV4A, see Signing AWS API requests in the *AWS General Reference*.

> **Note**
>
> To use SigV4A with temporary security credentials—for example, when using AWS Identity and Access Management (IAM) roles—you can request the temporary credentials from a Regional AWS Security Token Service (AWS STS) endpoint. If you request temporary credentials from the global AWS STS endpoint (`sts.amazonaws.com`), then you must first set the Region compatibility of session tokens for the global endpoint to be valid in all AWS Regions. For more information, see Managing AWS STS in an AWS Region in the *IAM User Guide*.

Amazon S3 API operations

- `CopyObject` is supported as a destination only when using the Multi-Region Access Point ARN.
- The S3 Batch Operations feature isn't supported.

AWS SDKs

Certain AWS SDKs aren't supported. To confirm which AWS SDKs are supported for Multi-Region Access Points, see Compatibility with AWS SDKs.

Service quotas

Be aware of the following service quota limitations:

- There is a maximum of 100 Multi-Region Access Points per account.
- There is a limit of 17 Regions for a single Multi-Region Access Point.

Creating, deleting, or modifying a Multi-Region Access Point

When you create, delete, or modify an Multi-Region Access Point, be aware of the following rules and restrictions:

- After you create a Multi-Region Access Point, you can't add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one. If a cross-account bucket in your Multi-Region Access Point is deleted, the only way to reconnect this bucket is to recreate the bucket, using the same name and Region in that account.
- Underlying buckets (in the same account) that are used in a Multi-Region Access Point can be deleted only after a Multi-Region Access Point is deleted.

Region support

Control plane requests

All control plane requests to create or maintain Multi-Region Access Points must be routed to the `US West (Oregon)` Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified.

For the Multi-Region Access Point failover control plane, requests must be routed to one of these five supported Regions:

- `US East (N. Virginia)`
- `US West (Oregon)`
- `Asia Pacific (Sydney)`
- `Asia Pacific (Tokyo)`
- `Europe (Ireland)`

Regions enabled by default

Your Multi-Region Access Point supports buckets in the following default AWS Regions (which are enabled by default in your AWS account):

- `US East (N. Virginia)`
- `US East (Ohio)`

- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)

AWS opt-in Regions

Your Multi-Region Access Point also supports buckets in the following opt-in AWS Regions (which are disabled by default in your AWS account):

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Hyderabad)
- Canada West (Calgary)
- Europe (Zurich)
- Europe (Milan)
- Europe (Spain)
- Israel (Tel Aviv)

- `Middle East (Bahrain)`
- `Middle East (UAE)`

> **Note**
>
> There are no additional costs for enabling an opt-in Region. However, creating or using a resource in a Multi-Region Access Point results in billing charges.

An opt-in Region must be manually enabled when configuring or creating your Multi-Region Access Point. For more information about opt-in Region behaviors for Multi-Region Access Points, see Configuring Multi-Region Access Point opt-in Regions. For information about how to enable an opt-in Region in your AWS account, see Enable or disable a Region for standalone accounts in the *AWS Account Management Reference Guide*.

Multi-Region Access Point request routing

When you make a request through a Multi-Region Access Point, Amazon S3 determines which of the buckets that are associated with the Multi-Region Access Point is closest to you. Amazon S3 then directs the request to that bucket, regardless of the AWS Region it is located in.

After the Multi-Region Access Point routes the request to the closest-proximity bucket, Amazon S3 processes the request as if you made it directly to that bucket. Multi-Region Access Points aren't aware of the data contents of an Amazon S3 bucket. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, you can configure S3 Cross-Region Replication (CRR). Then any bucket can fulfill the request successfully.

Amazon S3 directs Multi-Region Access Point requests according to the following rules:

- Amazon S3 optimizes requests to be fulfilled according to proximity. It looks at the buckets supported by the Multi-Region Access Point and relays the request to the bucket that has the closest proximity.
- If the request specifies an existing resource (for example, `GetObject`), Amazon S3 does *not* consider the name of the object when fulfilling the request. This means that even if an object exists in one bucket in the Multi-Region Access Point, your request can be routed to a bucket that doesn't contain the object. This situation will result in a 404 error message being returned to the client.

To avoid 404 errors, we recommend that you configure S3 Cross-Region Replication (CRR) for your buckets. Replication helps resolve the potential issue when the object that you want is in a bucket in the Multi-Region Access Point, but it's not located in the specific bucket that your request was routed to. For more information about configuring replication, see Configuring replication for use with Multi-Region Access Points.

To ensure that your requests are fulfilled by using the specific objects that you want, we also recommend that you turn on bucket versioning and include version IDs in your requests. This approach helps ensure that you have the correct version of the object that you are looking for. Versioning-enabled buckets can also help you recover objects from accidental overwrite. For more information, see Using S3 Versioning in S3 buckets.

- If the request is to create a resource (for example, `PutObject` or `CreateMultipartUpload`), Amazon S3 fulfills the request by using the closest-proximity bucket. For example, consider a video company that wants to support video uploads from anywhere in the world. When a user makes a PUT request to the Multi-Region Access Point, the object is put into the bucket with the closest proximity. To then make that uploaded video available to others around the world for download with the lowest latency, you can use CRR with bidirectional (two-way) replication. Using CRR with two-way replication keeps the contents of all the buckets that are associated with the Multi-Region Access Point synchronized. For more information about using replication with Multi-Region Access Points, see Configuring replication for use with Multi-Region Access Points.

Amazon S3 Multi-Region Access Points failover controls

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover.

For example, to perform failover to an AWS Region of your choice, you shift traffic from your primary (active) Region to your secondary (passive) Region. In an active-passive configuration like this, one bucket is active and accepting traffic, while the other bucket is passive and not accepting

traffic. The passive bucket is used for disaster recovery. When you initiate failover, all traffic (such as GET or PUT requests) is directed to the bucket in the active state (in one Region) and away from the bucket in the passive state (in another Region).

If you have S3 Cross-Region Replication (CRR) enabled with two-way replication rules, you can keep your buckets synchronized during a failover. In addition, if you have CRR enabled in an active-active configuration, Amazon S3 Multi-Region Access Points can also fetch data from the bucket location of closest proximity, which improves application performance.

AWS Region support

With Amazon S3 Multi-Region Access Points failover controls, your S3 buckets can be in any of the 17 Regions where Multi-Region Access Points are supported. You can initiate failover across any two Regions at one time.

> **Note**
>
> Although failover is initiated between only two Regions at one time, you can separately update the routing statuses for multiple Regions at the same time in your Multi-Region Access Point.

The following topics demonstrate how to use and manage Amazon S3 Multi-Region Access Point failover controls.

Topics

- Amazon S3 Multi-Region Access Points routing states
- Using Amazon S3 Multi-Region Access Point failover controls
- Amazon S3 Multi-Region Access Point failover controls errors

Amazon S3 Multi-Region Access Points routing states

Your Amazon S3 Multi-Region Access Points failover configuration determines the routing status of the AWS Regions that are used with the Multi-Region Access Point. You can configure your Amazon S3 Multi-Region Access Point to be in an active-active state or active-passive state.

- **Active-active** – In an active-active configuration, all requests are automatically sent to the closest proximity AWS Region in your Multi-Region Access Point. After the Multi-Region Access

Point has been configured to be in an active-active state, all Regions can receive traffic. If traffic disruption occurs in an active-active configuration, network traffic will automatically be redirected to one of the active Regions.

- **Active-passive** – In an active-passive configuration, the active Regions in your Multi-Region Access Point receive traffic and the passive ones do not. If you intend to use S3 failover controls to initiate failover in a disaster situation, set up your Multi-Region Access Points in an active-passive configuration while you're testing and performing disaster-recovery planning.

Using Amazon S3 Multi-Region Access Point failover controls

This section explains how to manage and use your Amazon S3 Multi-Region Access Points failover controls by using the AWS Management Console.

There are two failover controls in the **Failover configuration** section on your Multi-Region Access Point details page in the AWS Management Console: **Edit routing status** and **Failover**. You can use these controls as follows:

- **Edit routing status** – You can manually edit the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status**. You can use **Edit routing status** for the following purposes:
  - To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
  - To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
  - To manually fail over your Regions
  - To manually switch traffic between Regions
- **Failover** – When you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

Editing the routing status of the Regions in your Multi-Region Access Point

You can manually update the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status** in the **Failover configuration** section on your Multi-Region Access Point details page. However, when you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to

be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

You can use **Edit routing status** (as described in the following procedure) for the following purposes:

- To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
- To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
- To manually fail over your Regions
- To manually switch traffic between Regions

Using the S3 console

To update the routing status of the Regions in your Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to update.
5. Choose the **Replication and failover** tab.
6. Select one or more Regions that you want to edit the routing status of.

   > **Note**
   >
   > To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

7. Choose **Edit routing status**.
8. In the dialog box that appears, select **Active** or **Passive** for the **Routing status** for each Region.

   An active state allows traffic to be routed to the Region. A passive state stops any traffic from being directed to the Region.

If you are creating a failover configuration for your Multi-Region Access Point or initiating failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

9. Choose **Save routing status**. It takes about 2 minutes for traffic to be redirected.

After you submit the routing status of the AWS Regions for your Multi-Region Access Point, you can verify your routing status changes. To verify these changes, go to Amazon CloudWatch at https://console.aws.amazon.com/cloudwatch/ to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

Using the AWS CLI

> **Note**
>
> You can run Multi-Region Access Point AWS CLI routing commands against any of these five Regions:
>
> - `ap-southeast-2`
> - `ap-northeast-1`
> - `us-east-1`
> - `us-west-2`
> - `eu-west-1`

The following example command updates your current Multi-Region Access Point route configuration. To update the active or passive status of a bucket, set the `TrafficDialPercentage` value to `100` for active and to `0` for passive. In this example, *`amzn-s3-demo-bucket1`* is set to active, and *`amzn-s3-demo-bucket2`* is set to passive. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 123456789012
--mrap MultiRegionAccessPoint_ARN
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
```

```
                Bucket=amzn-s3-demo-bucket2
,TrafficDialPercentage=0
```

The following example command gets your updated Multi-Region Access Point routing configuration. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 123456789012
--mrap MultiRegionAccessPoint_ARN
```

Initiating failover

When you initiate failover by choosing **Failover** in the **Failover configuration** section on your Multi-Region Access Point details page, Amazon S3 request traffic automatically gets shifted to an alternate AWS Region. The failover process is completed within 2 minutes.

You can initiate a failover across any two AWS Regions at one time (of the 17 Regions where Multi-Region Access Points are supported). Failover events are then logged in AWS CloudTrail. Upon failover completion, you can monitor Amazon S3 traffic and any traffic routing updates to the new active Region in Amazon CloudWatch.

> **Important**
>
> To keep all metadata and objects in sync across buckets during data replication, we recommend that you create two-way replication rules and enable replica modification sync before configuring your failover controls.
> Two-way replication rules help ensure that when data is written to the Amazon S3 bucket that traffic fails over to, that data is then replicated back to the source bucket. Replica modification sync helps ensure that object metadata is also synchronized between buckets during two-way replication.
> For more information about configuring replication to support failover, see the section called “Bucket replication”.

To initiate failover between replicated buckets

1. Sign in to the AWS Management Console.

2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to use to initiate failover.
5. Choose the **Replication and failover** tab.
6. Scroll down to the **Failover configuration** section and select two AWS Regions.

> **Note**
>
> To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point. An active state allows traffic to be directed to a Region. A passive state stops any traffic from being directed to the Region.

7. Choose **Failover**.
8. In the dialog box, choose **Failover** again to initiate the failover process. During this process, the routing statuses of the two Regions are automatically switched. All new traffic is directed to the Region that becomes active, and traffic stops being directed to the Region that becomes passive. It takes about 2 minutes for traffic to be redirected.

   After you initiate the failover process, you can verify your traffic changes. To verify these changes, go to Amazon CloudWatch at https://console.aws.amazon.com/cloudwatch/ to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

Viewing your Amazon S3 Multi-Region Access Point routing controls

Using the S3 console

To view the routing controls for your Amazon S3 Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to review.

5. Choose the **Replication and failover** tab. This page displays the routing configuration details and summary for your Multi-Region Access Point, associated replication rules, and replication metrics. You can see the routing status of your Regions in the **Failover configuration** section.

Using the AWS CLI

The following example AWS CLI command gets your current Multi-Region Access Point route configuration for the specified Region. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 123456789012
--mrap MultiRegionAccessPoint_ARN
```

> **Note**
>
> This command can only be executed against these five Regions:
>
> - ap-southeast-2
> - ap-northeast-1
> - us-east-1
> - us-west-2
> - eu-west-1

Amazon S3 Multi-Region Access Point failover controls errors

When you update the failover configuration for your Multi-Region Access Point, you might encounter one of these errors:

- HTTP 400 Bad Request: This error can occur if you enter an invalid Multi-Region Access Point ARN while updating your failover configuration. You can confirm your Multi-Region Access Point ARN by reviewing your Multi-Region Access Point policy. To review or update your Multi-Region Access Point policy, see Editing the Multi-Region Access Point policy. This error can also occur if you use an empty string or a random string while updating your Amazon S3 Multi-Region Access Point failover controls. Make sure to use the Multi-Region Access Point ARN format:

`arn:aws:s3::account-id:accesspoint/MultiRegionAccessPoint_alias`

- HTTP 503 Slow Down: This error occurs if you send too many requests in a short period of time. Rejected requests will result in an error.
- HTTP 409 Conflict: This error occurs when two or more concurrent route configuration update requests are targeting a single Multi-Region Access Point. The first request succeeds, but any other requests fail with an error.
- HTTP 405 Method Not Allowed: This error occurs when you've selected a Multi-Region Access Point with only one AWS Region when initiating failover. You must select two Regions before you can initiate failover. Otherwise, an error is returned.

Configuring replication for use with Multi-Region Access Points

When you make a request to a Multi-Region Access Point endpoint, Amazon S3 automatically routes the request to the bucket that is closest to you. Amazon S3 doesn't consider the contents of the request when making this decision. If you make a request to `GET` an object, your request might be routed to a bucket that doesn't have a copy of this object. If that happens, you receive an HTTP status code 404 (Not Found) error. For more information about Multi-Region Access Point request routing, see the section called “Request routing”.

If you want the Multi-Region Access Point to be able to retrieve the object regardless of which bucket receives the request, you must configure Amazon S3 Cross-Region Replication (CRR).

For example, consider a Multi-Region Access Point with three buckets:

- A bucket named *amzn-s3-demo-bucket1* in the Region `US West (Oregon)` that contains the object `my-image.jpg`
- A bucket named *amzn-s3-demo-bucket2* in the Region `Asia Pacific (Mumbai)` that contains the object `my-image.jpg`
- A bucket named *amzn-s3-demo-bucket* in the Region `Europe (Frankfurt)` that doesn't contain the object `my-image.jpg`

In this situation, if you make a `GetObject` request for the object `my-image.jpg`, the success of that request depends upon which bucket receives your request. Because Amazon S3 doesn't consider the contents of the request, it might route your `GetObject` request to the *amzn-s3-demo-bucket* bucket if that bucket responds of closest proximity. Even though your object is in

a bucket in the Multi-Region Access Point, you will get an HTTP 404 Not Found error because the individual bucket that received your request didn't have the object.

Enabling Cross-Region Replication (CRR) helps avoid this result. With appropriate replication rules, the `my-image.jpg` object is copied over to the *`amzn-s3-demo-bucket`* bucket. Therefore, if Amazon S3 routes your request to that bucket, you can now retrieve the object.

Replication works as normal with buckets that are assigned to a Multi-Region Access Point. Amazon S3 doesn't perform any special replication handling with buckets that are in Multi-Region Access Points. For more information about configuring replication in your buckets, see Setting up live replication overview.

Recommendations for using replication with Multi-Region Access Points

For the best replication performance when working with Multi-Region Access Points, we recommend the following:

- Configure S3 Replication Time Control (S3 RTC). To replicate your data across different Regions within a predictable time frame, you can use S3 RTC. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called “Using S3 Replication Time Control”. There are additional charges for S3 RTC. For information, see Amazon S3 pricing.
- Use two-way (bidirectional) replication to support keeping buckets synchronized when buckets are updated through the Multi-Region Access Point. For more information, see the section called “Create two-way replication rules for your Multi-Region Access Point”.
- Create cross-account Multi-Region Access Points to replicate data to buckets in separate AWS accounts. This approach provides account-level separation, so that data can be accessed from and replicated across different accounts in different Regions other than the source bucket. Setting up cross-account Multi-Region Access Points comes at no additional cost. If you're a bucket owner but don't own the Multi-Region Access Point, you pay only for data transfer and request costs. Multi-Region Access Point owners pay for data routing and internet-acceleration costs. For more information, see Amazon S3 pricing.
- Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see Enabling replica modification sync.
- Enable Amazon CloudWatch metrics to monitor replication events. CloudWatch metrics fees apply. For more information, see Amazon CloudWatch pricing.

Topics

- Create one-way replication rules for your Multi-Region Access Point
- Create two-way replication rules for your Multi-Region Access Point
- View the replication rules for your Multi-Region Access Point

Create one-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A one-way replication rule helps ensure that data is fully replicated from a source bucket in one AWS Region to a destination bucket in another Region. When one-way replication is set up, a replication rule from the source bucket (*amzn-s3-demo-bucket*) to the destination bucket (*amzn-s3-demo-bucket*) is created. Like all replication rules, you can apply the one-way replication rule to the entire Amazon S3 bucket or to a subset of objects that are filtered by a prefix or object tags.

> **Important**
>
> We recommend using one-way replication if your users will only be consuming the objects in your destination buckets. If your users will be uploading or modifying the objects in your destination buckets, use two-way replication to keep all of your buckets in sync. We also recommend two-way replication if you plan to use your Multi-Region Access Point for failover. To set up two-way replication, see the section called "Create two-way replication rules for your Multi-Region Access Point".

To create a one-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**. Make sure that you have sufficient permissions to create the replication rule, or versioning will be disabled.

> **Note**
>
> You can create replication rules only for buckets in your own account. To create replication rules for external buckets, the bucket owners must create the replication rules for those buckets.

6. On the **Create replication rules** page, choose the **Replicate objects from one or more source buckets to one or more destination buckets** template.

> **Important**
>
> When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.
> To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, SDKs, or REST API. For more information, see Replication configuration file elements.

7. In the **Source and destination** section, under **Source buckets**, select one or more buckets that you want to replicate objects from. All buckets (source and destination) that are chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see Using versioning in Amazon S3 buckets.

   Under **Destination buckets**, select one or more buckets that you want to replicate objects to.

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

> **Note**
>
> You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

   - To replicate the whole bucket, choose **Apply to all objects in the bucket**.

- To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

  You can filter your objects by using a prefix, object tags, or a combination of both.

  - To limit replication to all objects that have names that begin with the same string (for example `pictures`), enter a prefix in the **Prefix** box.

    If you enter a prefix that is the name of a folder, you must use a delimiter such as a `/` (forward slash) to indicate its level of hierarchy (for example, `pictures/`). For more information about prefixes, see Organizing objects using prefixes.

  - To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see Tagging your objects.

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

> **Note**
>
> We recommend that you apply the following options:
>
> - **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called “Using S3 Replication Time Control”.
> - **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.
> - **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see Replicating delete markers between buckets.
>
> There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see Amazon S3 Pricing and Amazon CloudWatch pricing.

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new one-way replication rule.

Create two-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A two-way replication rule (also known as a bidirectional replication rule) ensures that data is fully synchronized between two or more buckets in different AWS Regions. When two-way replication is set up, a replication rule from the source bucket (DOC-EXAMPLE-BUCKET-1) to the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) is created. Then, a second replication rule from the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) to the source bucket (DOC-EXAMPLE-BUCKET-1) is created.

Like all replication rules, you can apply the two-way replication rule to the entire Amazon S3 bucket or to a subset of objects filtered by a prefix or object tags. You can also keep metadata changes to your objects in sync by enabling replica modification sync for each replication rule. You can enable replica modification sync through the Amazon S3 console, the AWS CLI, the AWS SDKs, the Amazon S3 REST API, or AWS CloudFormation.

To monitor the replication progress of objects and object metadata in Amazon CloudWatch, enable S3 Replication metrics and notifications. For more information, see Monitoring progress with replication metrics and Amazon S3 event notifications.

To create a two-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to update.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**.
6. On the **Create replication rules** page, choose the **Replicate objects among all specified buckets** template. The **Replicate objects among all specified buckets** template sets up two-way replication (with failover capabilities) for your buckets.

> **Important**
>
> When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.
> To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see Replication configuration file elements.

7. In the **Buckets** section, select at least two buckets that you want to replicate objects from. All buckets chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see Using versioning in Amazon S3 buckets.

   > **Note**
   >
   > Make sure that you have the required read and replicate permissions to establish replication, or you will encounter errors. For more information, see Creating an IAM role.

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

   > **Note**
   >
   > You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

   - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
   - To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

     You can filter your objects by using a prefix, object tags, or a combination of both.

- To limit replication to all objects that have names that begin with the same string (for example `pictures`), enter a prefix in the **Prefix** box.

  If you enter a prefix that is the name of a folder, you must use a `/` (forward slash) as the last character (for example, `pictures/`).

- To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see Tagging your objects.

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

> **Note**
>
> We recommend that you apply the following options, especially if you intend to configure your Multi-Region Access Point to support failover:
>
> - **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see the section called "Using S3 Replication Time Control".
> - **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.
> - **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see Replicating delete markers between buckets.
> - **Replica modification sync** – Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see Enabling replica modification sync.
>
> There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see Amazon S3 Pricing and Amazon CloudWatch pricing.

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.

12. Choose **Create replication rules** to create and save your new two-way replication rules.

View the replication rules for your Multi-Region Access Point

With Multi-Region Access Points, you can either set up one-way replication rules or two-way (bidirectional) replication rules. For information about how to manage your replication rules, see Managing replication rules by using the Amazon S3 console.

To view the replication rules for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section. This section lists all of the replication rules that have been created for your Multi-Region Access Point.

> **Note**
>
> If you've added a bucket from another account to this Multi-Region Access Point, you must have the `s3:GetBucketReplication` permission from the bucket owner to view the replication rules for that bucket.

Using Multi-Region Access Points with supported API operations

Amazon S3 provides a set of operations to manage Multi-Region Access Points. Amazon S3 processes some of these operations synchronously and some asynchronously. When you invoke an asynchronous operation, Amazon S3 first synchronously authorizes the requested operation. If authorization is successful, Amazon S3 returns a token that you can use to track the progress and results of the requested operation.

> **Note**
>
> Requests that are made through the Amazon S3 console are always synchronous. The console waits until the request is completed before allowing you to submit another request.

You can view the current status and results of asynchronous operations by using the console, or you can use `DescribeMultiRegionAccessPointOperation` in the AWS CLI, AWS SDKs, or REST API. Amazon S3 provides a tracking token in the response to an asynchronous operation. You include that tracking token as an argument to `DescribeMultiRegionAccessPointOperation`. When you include the tracking token, Amazon S3 then returns the current status and results of the specified operation, including any errors or relevant resource information. Amazon S3 performs `DescribeMultiRegionAccessPointOperation` operations synchronously.

All control plane requests to create or maintain Multi-Region Access Points must be routed to the `US West (Oregon)` Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified. For the Multi-Region Access Point failover control plane, the request must be routed to one of the five supported Regions. For more information about Multi-Region Access Point supported Regions, see Multi-Region Access Point restrictions and limitations.

In addition, you must grant the `s3:ListAllMyBuckets` permission to the user, role, or other AWS Identity and Access Management (IAM) entity that makes a request to manage a Multi-Region Access Point.

The following examples demonstrate how to use Multi-Region Access Points with compatible operations in Amazon S3.

Topics

- Multi-Region Access Point compatibility with AWS services and AWS SDKs
- Multi-Region Access Point compatibility with S3 operations
- View your Multi-Region Access Point routing configuration
- Update your underlying Amazon S3 bucket policy
- Update a Multi-Region Access Point route configuration
- Add an object to a bucket in your Multi-Region Access Point
- Retrieve objects from your Multi-Region Access Point

- List objects that are stored in a bucket underlying your Multi-Region Access Point
- Use a presigned URL with Multi-Region Access Points
- Use a bucket that's configured with Requester Pays with Multi-Region Access Points

Multi-Region Access Point compatibility with AWS services and AWS SDKs

To use a Multi-Region Access Point with applications that require an Amazon S3 bucket name, use the Amazon Resource Name (ARN) of the Multi-Region Access Point when making requests by using an AWS SDK. To check which AWS SDKs are compatible with Multi-Region Access Points, see Compatibility with AWS SDKs.

Multi-Region Access Point compatibility with S3 operations

You can use use the following Amazon S3 data plane API operations to perform actions on objects in buckets that are associated with your Multi-Region Access Point. The following S3 operations can accept Multi-Region Access Point ARNs:

- AbortMultipartUpload
- CompleteMultipartUpload
- CreateMultipartUpload
- DeleteObject
- DeleteObjectTagging
- GetObject
- GetObjectAcl
- GetObjectLegalHold
- GetObjectRetention
- GetObjectTagging
- HeadObject
- ListMultipartUploads
- ListObjectsV2
- ListParts
- PutObject
- PutObjectAcl
- PutObjectLegalHold

- PutObjectRetention
- PutObjectTagging
- RestoreObject
- UploadPart

> **Note**
>
> Multi-Region Access Points supports copy operations using Multi-Region Access Points only as a destination when using the Multi-Region Access Point ARN.

You can use the following Amazon S3 control plane operations to create and manage your Multi-Region Access Points:

- CreateMultiRegionAccessPoint
- DescribeMultiRegionAccessPointOperation
- GetMultiRegionAccessPoint
- GetMultiRegionAccessPointPolicy
- GetMultiRegionAccessPointPolicyStatus
- GetMultiRegionAccessPointRoutes
- ListMultiRegionAccessPoints
- PutMultiRegionAccessPointPolicy
- SubmitMultiRegionAccessPointRoutes

View your Multi-Region Access Point routing configuration

AWS CLI

The following example command retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 111122223333
```

```
--mrap arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap
```

SDK for Java

The following SDK for Java code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_EAST_1)
    .credentialsProvider(credentialsProvider)
    .build();

GetMultiRegionAccessPointRoutesRequest request =
 GetMultiRegionAccessPointRoutesRequest.builder()
    .accountId("111122223333")
    .mrap("arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap")
    .build();

GetMultiRegionAccessPointRoutesResponse response =
 s3ControlClient.getMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'us-east-1'

const s3ControlClient = new S3ControlClient({
  region: REGION
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new GetMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap',
      })
    )
    console.log('Success', data)
```

```
    return data
  } catch (err) {
    console.log('Error', err)
  }
}

run()
```

SDK for Python (Boto3)

The following AWS SDK for Python (Boto3) code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.get_multi_region_access_point_routes(
        AccountId=111122223333,
        Mrap=arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap)['Routes']
```

Update your underlying Amazon S3 bucket policy

To grant proper access, you must also update the underlying Amazon S3 bucket policy. The following examples delegate access control to the Multi-Region Access Point policy. After you delegate access control to the Multi-Region Access Point policy, the bucket policy is no longer used for access control when requests are made through the Multi-Region Access Point.

Here's an example bucket policy that delegates access control to the Multi-Region Access Point policy. To use this example bucket policy, replace the *user input placeholders* with your own information. To apply this policy through the AWS CLI `put-bucket-policy` command, as shown in the next example, save the policy in a file, for example, `policy.json`.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::444455556666:root"
      },
```

```
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ],
      "Condition": {
        "StringEquals": {
          "s3:DataAccessPointAccount": "444455556666"
        }
      }
    }
  ]
}
```

The following `put-bucket-policy` example command associates the updated S3 bucket policy with your S3 bucket:

```
aws s3api put-bucket-policy
  --bucket amzn-s3-demo-bucket
  --policy file:///tmp/policy.json
```

Update a Multi-Region Access Point route configuration

The following example command updates the Multi-Region Access Point route configuration. Multi-Region Access Point route commands can be run against the following five Regions:

- `ap-southeast-2`
- `ap-northeast-1`
- `us-east-1`
- `us-west-2`
- `eu-west-1`

In a Multi-Region Access Point routing configuration, you can set buckets to an active or passive routing status. Active buckets receive traffic, whereas passive buckets do not. You can set a bucket's

routing status by setting the `TrafficDialPercentage` value for the bucket to `100` for active or `0` for passive.

AWS CLI

The following example command updates your Multi-Region Access Point routing configuration. In this example, *amzn-s3-demo-bucket1* is set to active status and *amzn-s3-demo-bucket2* is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 111122223333
--mrap arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
                Bucket=amzn-s3-demo-bucket2,TrafficDialPercentage=0
```

SDK for Java

The following SDK for Java code updates your Multi-Region Access Point routing configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.ap-southeast-2)
    .credentialsProvider(credentialsProvider)
    .build();

SubmitMultiRegionAccessPointRoutesRequest request =
 SubmitMultiRegionAccessPointRoutesRequest.builder()
    .accountId("111122223333")
    .mrap("arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap")
    .routeUpdates(
        MultiRegionAccessPointRoute.builder()
            .region("eu-west-1")
            .trafficDialPercentage(100)
            .build(),
        MultiRegionAccessPointRoute.builder()
            .region("ca-central-1")
            .bucket("111122223333")
            .trafficDialPercentage(0)
            .build()
```

```
    )
    .build();

SubmitMultiRegionAccessPointRoutesResponse response =
 s3ControlClient.submitMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'ap-southeast-2'

const s3ControlClient = new S3ControlClient({
  region: REGION
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new SubmitMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap',
        RouteUpdates: [
          {
            Region: 'eu-west-1',
            TrafficDialPercentage: 100,
          },
          {
            Region: 'ca-central-1',
            Bucket: 'amzn-s3-demo-bucket1',
            TrafficDialPercentage: 0,
          },
        ],
      })
    )
    console.log('Success', data)
    return data
  } catch (err) {
    console.log('Error', err)
  }
}
```

```
run()
```

SDK for Python (Boto3)

The following SDK for Python (Boto3) code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.submit_multi_region_access_point_routes(
        AccountId=111122223333,
        Mrap=arn:aws:s3::111122223333:accesspoint/abcdef0123456.mrap,
        RouteUpdates= [{
            'Bucket': amzn-s3-demo-bucket,
            'Region': ap-southeast-2,
            'TrafficDialPercentage': 10
        }])
```

Add an object to a bucket in your Multi-Region Access Point

To add an object to the bucket that's associated with the Multi-Region Access Point, you can use the PutObject operation. To keep all buckets in the Multi-Region Access Point in sync, enable Cross-Region Replication.

> **Note**
>
> To use this operation, you must have the `s3:PutObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permission requirements, see Permissions.

AWS CLI

The following example data plane request uploads *example.txt* to the specified Multi-Region Access Point. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api put-object --bucket
 arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap --key example.txt --
body example.txt
```

SDK for Java

```
S3Client s3Client = S3Client.builder()
        .build();

PutObjectRequest objectRequest = PutObjectRequest.builder()
        .bucket("arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap")
        .key("example.txt")
        .build();

s3Client.putObject(objectRequest, RequestBody.fromString("Hello S3!"));
```

SDK for JavaScript

```
const client = new S3Client({});

async function putObjectExample() {
    const command = new PutObjectCommand({
        Bucket: "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap",
        Key: "example.txt",
        Body: "Hello S3!",
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python (Boto3)

```
import boto3

client = boto3.client('s3')
client.put_object(
    Bucket='arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt',
    Body='Hello S3!'
)
```

Retrieve objects from your Multi-Region Access Point

To retrieve objects from the Multi-Region Access Point, you can use the GetObject operation.

> **Note**
>
> To use this API operation, you must have the `s3:GetObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permissions requirements, see Permissions.

AWS CLI

The following example data plane request retrieves *example.txt* from the specified Multi-Region Access Point and downloads it as *downloaded_example.txt*. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket
 arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap --
key example.txt downloaded_example.txt
```

SDK for Java

```
S3Client s3 = S3Client
   .builder()
   .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap")
    .key("example.txt")
    .build();

s3Client.getObject(getObjectRequest);
```

SDK for JavaScript

```
const client = new S3Client({})

async function getObjectExample() {
    const command = new GetObjectCommand({
```

```
        Bucket: "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap",
        Key: "example.txt"
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python (Boto3)

```
import boto3

client = boto3.client('s3')
client.get_object(
    Bucket='arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt'
)
```

List objects that are stored in a bucket underlying your Multi-Region Access Point

To return a list of objects that are stored in a bucket underlying your Multi-Region Access Point, use the ListObjectsV2 operation. In the following example command, all objects for the specified Multi-Region Access Point are listed by using the ARN for the Multi-Region Access Point. In this case, the Multi-Region Access Point ARN is:

`arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap`

> **Note**
>
> To use this API operation, you must have the `s3:ListBucket` permission for the Multi-Region Access Point and the underlying bucket. For more information about Multi-Region Access Point permissions requirements, see Permissions.

AWS CLI

The following example data plane request lists the objects in the bucket that underlies the Multi-Region Access Point that's specified by the ARN. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api list-objects-v2 --bucket
 arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap
```

SDK for Java

```
S3Client s3Client = S3Client.builder()
        .build();

String bucketName = "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap";

ListObjectsV2Request listObjectsRequest = ListObjectsV2Request
    .builder()
    .bucket(bucketName)
    .build();

 s3Client.listObjectsV2(listObjectsRequest);
```

SDK for JavaScript

```
const client = new S3Client({});

async function listObjectsExample() {
    const command = new ListObjectsV2Command({
        Bucket: "arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap",
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python (Boto3)

```
import boto3

client = boto3.client('s3')
client.list_objects_v2(
    Bucket='arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap'
)
```

Use a presigned URL with Multi-Region Access Points

You can use a presigned URL to generate a URL that allows others to access your Amazon S3 buckets through an Amazon S3 Multi-Region Access Point. When you create a presigned URL, you associate it with a specific object action, such as an S3 upload (`PutObject`) or an S3 download (`GetObject`). You can share the presigned URL, and anyone with access to it can perform the action embedded in the URL as if they were the original signing user.

Presigned URLs have an expiration date. When the expiration time is reached, the URL will no longer work.

Before you use S3 Multi-Region Access Points with presigned URLs, check the AWS SDK compatibility with the SigV4A algorithm. Verify that your SDK version supports SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about using presigned URLs with Amazon S3, see Sharing objects by using presigned URLs.

The following examples show how you can use Multi-Region Access Points with presigned URLs. To use these examples, replace the *`user input placeholders`* with your own information.

AWS CLI

```
aws s3 presign
 arn:aws:s3::123456789012:accesspoint/MultiRegionAccessPoint_alias/example-file.txt
```

SDK for Python (Boto3)

```
import logging
import boto3
from botocore.exceptions import ClientError
```

```
s3_client = boto3.client('s3',aws_access_key_id='xxx',aws_secret_access_key='xxx')
s3_client.generate_presigned_url(HttpMethod='PUT',ClientMethod="put_object",
 Params={'Bucket':'arn:aws:s3::123456789012:accesspoint/
abcdef0123456.mrap','Key':'example-file'})
```

SDK for Java

```
S3Presigner s3Presigner = S3Presigner.builder()
    .credentialsProvider(StsAssumeRoleCredentialsProvider.builder()
        .refreshRequest(assumeRole)
        .stsClient(stsClient)
        .build())
    .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3::123456789012:accesspoint/abcdef0123456.mrap")
    .key("example-file")
    .build();

GetObjectPresignRequest preSignedReq = GetObjectPresignRequest.builder()
    .getObjectRequest(getObjectRequest)
    .signatureDuration(Duration.ofMinutes(10))
    .build();

PresignedGetObjectRequest presignedGetObjectRequest =
 s3Presigner.presignGetObject(preSignedReq);
```

Note

To use SigV4A with temporary security credentials—for example, when using IAM roles—make sure that you request the temporary credentials from a Regional endpoint in AWS Security Token Service (AWS STS), instead of a global endpoint. If you use the global endpoint for AWS STS (`sts.amazonaws.com`), AWS STS will generate temporary credentials from a global endpoint, which isn't supported by Sig4A. As a result, you'll get an error. To resolve this issue, use any of the listed Regional endpoints for AWS STS.

Use a bucket that's configured with Requester Pays with Multi-Region Access Points

If an S3 bucket that is associated with your Multi-Region Access Points is configured to use Requester Pays, the requester will pay for the bucket request, the download, and any Multi-Region Access Points related costs. For more information, see Amazon S3 pricing.

Here's an example of a data plane request to a Multi-Region Access Point that is connected to a Requester Pays bucket.

AWS CLI

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify `--request-payer requester` as part of your get-object request. You must also specify the name of the file in the bucket and the location where the downloaded file should be stored.

```
aws s3api get-object --bucket MultiRegionAccessPoint_ARN --request-payer requester
 --key example-file-in-bucket.txt example-location-of-downloaded-file.txt
```

SDK for Java

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify the `RequestPayer.REQUESTER` as part of your `GetObject` request. You must also specify the name of the file in the bucket, as well as the location where it should be stored.

```
GetObjectResponse getObjectResponse = s3Client.getObject(GetObjectRequest.builder()
    .key("example-file.txt")
    .bucket("arn:aws:s3::
123456789012:accesspoint/abcdef0123456.mrap")
    .requestPayer(RequestPayer.REQUESTER)
    .build()
).response();
```

Monitoring and logging requests made through a Multi-Region Access Point to underlying resources

Amazon S3 logs requests made through Multi-Region Access Points and requests made to the API operations that manage them, such as `CreateMultiRegionAccessPoint` and

`GetMultiRegionAccessPointPolicy`. Requests made to Amazon S3 through a Multi-Region Access Point appear in your Amazon S3 server access logs and AWS CloudTrail logs with the Multi-Region Access Point hostname. An access point's hostname takes the form *`MRAP_alias`*`.accesspoint.s3-global.amazonaws.com`. For example, suppose that you have the following bucket and Multi-Region Access Point configuration:

- A bucket named `my-bucket-usw2` in the Region `us-west-2` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-aps1` in the Region `ap-south-1` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-euc1` in the Region `eu-central-1` that doesn't contain an object named `my-image.jpg`.
- A Multi-Region Access Point named `my-mrap` with the alias `mfzwi23gnjvgw.mrap` that is configured to fulfill requests from all three buckets.
- Your AWS account ID is `123456789012`.

A request made to retrieve `my-image.jpg` directly through any of the buckets appears in your logs with a hostname of *`bucket_name`*`.s3.`*`Region`*`.amazonaws.com`.

If you make the request through the Multi-Region Access Point instead, Amazon S3 first determines which of the buckets in the different Regions is closest. After Amazon S3 determines which bucket to use to fulfill the request, it sends the request to that bucket and logs the operation by using the Multi-Region Access Point hostname. In this example, if Amazon S3 relays the request to `my-bucket-aps1`, your logs will reflect a successful `GET` request for `my-image.jpg` from `my-bucket-aps1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Important

Multi-Region Access Points aren't aware of the data contents of the underlying buckets. Therefore, the bucket that gets the request might not contain the requested data. For example, if Amazon S3 determines that the `my-bucket-euc1` bucket is the closest, your logs will reflect a failed `GET` request for `my-image.jpg` from `my-bucket-euc1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. If the request was routed to `my-bucket-usw2` instead, your logs would indicate a successful `GET` request.

For more information about Amazon S3 server access logs, see Logging requests with server access logging. For more information about AWS CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

Monitoring and logging requests made to Multi-Region Access Point management API operations

Amazon S3 provides several API operations to manage Multi-Region Access Points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you make requests to these API operations by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, Amazon S3 processes these requests asynchronously. Provided that you have the appropriate permissions for the request, Amazon S3 returns a token for these requests. You can use this token with `DescribeAsyncOperation` to help you to view the status of ongoing asynchronous operations. Amazon S3 processes `DescribeAsyncOperation` requests synchronously. To view the status of asynchronous requests, you can use the Amazon S3 console, AWS CLI, SDKs, or REST API.

> **Note**
>
> The console displays only the status of asynchronous requests that were made within the previous 14 days. To view the status of older requests, use the AWS CLI, SDKs, or REST API.

Asynchronous management operations can be in one of several states:

NEW

Amazon S3 has received the request and is preparing to perform the operation.

IN_PROGRESS

Amazon S3 is currently performing the operation.

SUCCESS

The operation succeeded. The response includes relevant information, such as the Multi-Region Access Point alias for a `CreateMultiRegionAccessPoint` request.

FAILED

The operation failed. The response includes an error message that indicates the reason for the request failure.

Using AWS CloudTrail with Multi-Region Access Points

You can use AWS CloudTrail to view, search, download, archive, analyze, and respond to account activity across your AWS infrastructure. With Multi-Region Access Points and CloudTrail logging, you can identify the following:

- Who or what took which action
- Which resources were acted upon
- When the event occurred
- Other details regarding the event

You can use this logging information to help you analyze and respond to activity that occurred through your Multi-Region Access Points.

How to set up AWS CloudTrail for Multi-Region Access Points

To enable CloudTrail logging for any operations related to creating or maintaining Multi-Region Access Points, you must configure CloudTrail logging to record the events in the US West (Oregon) Region. You must set up your logging configuration this way regardless of which Region you are in when making the request, or which Regions the Multi-Region Access Point supports. All requests to create or maintain a Multi-Region Access Point are routed through the US West (Oregon) Region. We recommend that you either add this Region to an existing trail or create a new trail that contains this Region and all the Regions associated with the Multi-Region Access Point.

Amazon S3 logs all requests made through a Multi-Region Access Point and requests made to the API operations that manage access points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you log these requests through a Multi-Region Access Point, they appear in your AWS CloudTrail logs with the hostname of the Multi-Region Access Point. For example, if you make requests to a bucket through a Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, the entries in the CloudTrail log will have a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Multi-Region Access Points route requests to the closest bucketBecause of this behavior, when you are looking at the CloudTrail logs for a Multi-Region Access Point, you will see requests being made to the underlying buckets. Some of those requests might be direct requests to the bucket that are not routed through the Multi-Region Access Point. Keep this fact in mind when reviewing traffic. When a bucket is in a Multi-Region Access Point, requests can still be made to that bucket directly without going through the Multi-Region Access Point.

There are asynchronous events involved with creating and managing Multi-Region Access Points. Asynchronous requests don't have completion events in the CloudTrail log. For more information about asynchronous requests, see Monitoring and logging requests made to Multi-Region Access Point management API operations.

For more information about AWS CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

Retaining multiple versions of objects with S3 Versioning

Versioning in Amazon S3 is a means of keeping multiple variants of an object in the same bucket. You can use the S3 Versioning feature to preserve, retrieve, and restore every version of every object stored in your buckets. With versioning you can recover more easily from both unintended user actions and application failures. After versioning is enabled for a bucket, if Amazon S3 receives multiple write requests for the same object simultaneously, it stores all of those objects.

Versioning-enabled buckets can help you recover objects from accidental deletion or overwrite. For example, if you delete an object, Amazon S3 inserts a delete marker instead of removing the object permanently. The delete marker becomes the current object version. If you overwrite an object, it results in a new object version in the bucket. You can always restore the previous version. For more information, see Deleting object versions from a versioning-enabled bucket.

By default, S3 Versioning is disabled on buckets, and you must explicitly enable it. For more information, see Enabling versioning on buckets.

Note

- The SOAP API does not support S3 Versioning. SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features are not supported for SOAP.
- Normal Amazon S3 rates apply for every version of an object stored and transferred. Each version of an object is the entire object; it is not just a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Unversioned, versioning-enabled, and versioning-suspended buckets

Buckets can be in one of three states:

- Unversioned (the default)
- Versioning-enabled
- Versioning-suspended

You enable and suspend versioning at the bucket level. After you version-enable a bucket, it can never return to an unversioned state. But you can *suspend* versioning on that bucket.

The versioning state applies to all (never some) of the objects in that bucket. When you enable versioning in a bucket, all new objects are versioned and given a unique version ID. Objects that already existed in the bucket at the time versioning was enabled will thereafter *always* be versioned and given a unique version ID when they are modified by future requests. Note the following:

- Objects that are stored in your bucket before you set the versioning state have a version ID of `null`. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests. For more information, see Working with objects in a versioning-enabled bucket.
- The bucket owner (or any user with appropriate permissions) can suspend versioning to stop accruing object versions. When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. For more information, see Working with objects in a versioning-suspended bucket.

Using S3 Versioning with S3 Lifecycle

To customize your data retention approach and control storage costs, use object versioning with S3 Lifecycle. For more information, see Managing the lifecycle of objects. For information about creating S3 Lifecycle configurations using the AWS Management Console, AWS CLI, AWS SDKs, or the REST API, see Setting an S3 Lifecycle configuration on a bucket.

Important

If you have an object expiration lifecycle configuration in your unversioned bucket and you want to maintain the same permanent delete behavior when you enable versioning, you must add a noncurrent expiration configuration. The noncurrent expiration lifecycle configuration manages the deletes of the noncurrent object versions in the versioning-enabled bucket. (A versioning-enabled bucket maintains one current, and zero or

more noncurrent, object versions.) For more information, see Setting an S3 Lifecycle configuration on a bucket.

For information about working with S3 Versioning, see the following topics.

Topics

- How S3 Versioning works
- Enabling versioning on buckets
- Configuring MFA delete
- Working with objects in a versioning-enabled bucket
- Working with objects in a versioning-suspended bucket
- Troubleshooting versioning

How S3 Versioning works

You can use S3 Versioning to keep multiple versions of an object in one bucket so that you can restore objects that are accidentally deleted or overwritten. For example, if you apply S3 Versioning to a bucket, the following changes occur:

- If you delete an object, instead of removing the object permanently, Amazon S3 inserts a delete marker, which becomes the current object version. You can then restore the previous version. For more information, see Deleting object versions from a versioning-enabled bucket.
- If you overwrite an object, Amazon S3 adds a new object version in the bucket. The previous version remains in the bucket and becomes a noncurrent version. You can restore the previous version.

Note

Normal Amazon S3 rates apply for every version of an object that is stored and transferred. Each version of an object is the entire object; it is not a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see General purpose buckets configuration options.) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes an `Enabled` status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to `Suspended`.

> **Note**
>
> When you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. While this change is propagating, you may encounter intermittent `HTTP 404 NoSuchKey` errors for requests to objects created or updated after enabling versioning. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (`PUT` or `DELETE`) on objects in the bucket.

The bucket owner and all authorized AWS Identity and Access Management (IAM) users can enable versioning. The bucket owner is the AWS account that created the bucket. For more information about permissions, see Identity and Access Management for Amazon S3.

For more information about enabling and disabling S3 Versioning by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or REST API, see the section called "Enabling versioning on buckets".

Topics

- Version IDs
- Versioning workflows

Version IDs

If you enable versioning for a bucket, Amazon S3 automatically generates a unique version ID for the object that is being stored. For example, in one bucket you can have two objects with the same key (object name) but different version IDs, such as `photo.gif` (version 111111) and `photo.gif` (version 121212).
A versioning-enabled bucket that has two objects with the same key but different version IDs.

Each object has a version ID, whether or not S3 Versioning is enabled. If S3 Versioning is not enabled, Amazon S3 sets the value of the version ID to `null`. If you enable S3 Versioning, Amazon S3 assigns a version ID value for the object. This value distinguishes that object from other versions of the same key.

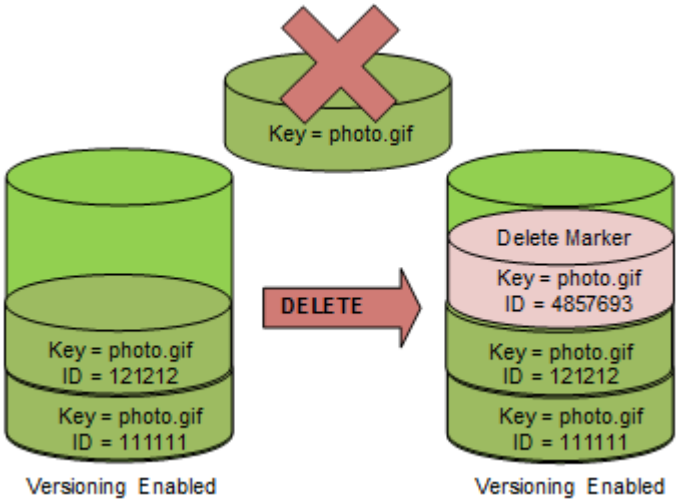
When you enable S3 Versioning on an existing bucket, objects that are already stored in the bucket are unchanged. Their version IDs (`null`), contents, and permissions remain the same. After you enable S3 Versioning, each object that is added to the bucket gets a version ID, which distinguishes it from other versions of the same key.

Only Amazon S3 generates version IDs, and they cannot be edited. Version IDs are Unicode, UTF-8 encoded, URL-ready, opaque strings that are no more than 1,024 bytes long. The following is an example:

```
3sL4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY+MTRCxf3vjVBH40Nr8X8gdRQBpUMLUo
```

> **Note**
>
> For simplicity, the other examples in this topic use much shorter IDs.

Versioning workflows



When you PUT an object in a versioning-enabled bucket, the noncurrent version is not overwritten. As shown in the following figure, when a new version of `photo.gif` is PUT into a bucket that already contains an object with the same name, the following behavior occurs:

- The original object (ID = 111111) remains in the bucket.
- Amazon S3 generates a new version ID (121212), and adds this newer version of the object to the bucket.

How S3 Versioning works when you PUT an object in a versioning-enabled bucket.

With this functionality, you can retrieve a previous version of an object if an object has been accidentally overwritten or deleted.

When you DELETE an object, all versions remain in the bucket, and Amazon S3 inserts a delete marker, as shown in the following figure.

The delete marker becomes the current version of the object. By default, GET requests retrieve the most recently stored version. Performing a `GET Object` request when the current version is a delete marker returns a `404 Not Found` error, as shown in the following figure.
A GetObject call for a delete marker returning a 404 (Not Found) error.

However, you can GET a noncurrent version of an object by specifying its version ID. In the following figure, you GET a specific object version, 111111. Amazon S3 returns that object version even though it's not the current version.

For more information, see Retrieving object versions from a versioning-enabled bucket.
How S3 Versioning works when you GET a noncurrent version in a versioning-enabled bucket.

You can permanently delete an object by specifying the version that you want to delete. Only the owner of an Amazon S3 bucket or an authorized IAM user can permanently delete a version. If your DELETE operation specifies the `versionId`, that object version is permanently deleted, and Amazon S3 doesn't insert a delete marker.
How `DELETE versionId` permanently deletes a specific object version.

You can add more security by configuring a bucket to enable multi-factor authentication (MFA) delete. When you enable MFA delete for a bucket, the bucket owner must include two forms of

authentication in any request to delete a version or change the versioning state of the bucket. For more information, see Configuring MFA delete.

When are new versions created for an object?

New versions of objects are created only when you PUT a new object. Be aware that certain actions, such as `CopyObject`, work by implementing a PUT operation.

Some actions that modify the current object don't create a new version because they don't PUT a new object. This includes actions such as changing the tags on an object.

> **Important**
>
> If you notice a significant increase in the number of HTTP 503 (Service Unavailable) responses received for Amazon S3 PUT or `DELETE` object requests to a bucket that has S3 Versioning enabled, you might have one or more objects in the bucket for which there are millions of versions. For more information, see the S3 Versioning section of Troubleshooting versioning.

Enabling versioning on buckets

You can use S3 Versioning to keep multiple versions of an object in one bucket. This section provides examples of how to enable versioning on a bucket using the console, REST API, AWS SDKs, and AWS Command Line Interface (AWS CLI).

> **Note**
>
> After enabling versioning on a bucket for the first time, it may take up to 15 minutes for the change to fully propagate across the S3 system. During this time, `GET` requests for objects created or updated after enabling versioning may result in `HTTP 404 NoSuchKey` errors. We recommend waiting 15 minutes after enabling versioning before performing any write operations (`PUT` or `DELETE`) on objects in the bucket. This waiting period helps avoid potential issues with object visibility and version tracking.

For more information about S3 Versioning, see Retaining multiple versions of objects with S3 Versioning. For information about working with objects that are in versioning-enabled buckets, see Working with objects in a versioning-enabled bucket.

To learn more about how to use S3 Versioning to protect data, see Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication.

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see General purpose buckets configuration options.) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes a status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

The bucket owner and all authorized users can enable versioning. The bucket owner is the AWS account that created the bucket (the root account). For more information about permissions, see Identity and Access Management for Amazon S3.

The following sections provide more detail about enabling S3 Versioning using the console, AWS CLI, and the AWS SDKs.

Using the S3 console

Follow these steps to use the AWS Management Console to enable versioning on an S3 bucket.

To enable or disable versioning on an S3 general purpose bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable versioning for.
4. Choose **Properties**.
5. Under **Bucket Versioning**, choose **Edit**.

6. Choose **Suspend** or **Enable**, and then choose **Save changes**.

> **Note**
>
> You can use AWS multi-factor authentication (MFA) with versioning. When you use MFA with versioning, you must provide your AWS account's access keys and a valid code from the account's MFA device to permanently delete an object version or suspend or reactivate versioning.
>
> To use MFA with versioning, you enable `MFA Delete`. However, you can't enable `MFA Delete` using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API. For more information, see Configuring MFA delete.

Using the AWS CLI

The following example enables versioning on an S3 general purpose bucket.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-
configuration Status=Enabled
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a physical MFA device. For physical MFA devices, in the `--mfa` parameter, pass a concatenation of the MFA device serial number, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-
configuration Status=Enabled,MFADelete=Enabled --mfa "SerialNumber 123456"
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a virtual MFA device. For virtual MFA devices, in the `--mfa` parameter, pass a concatenation of the MFA device ARN, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-
configuration Status=Enabled,MFADelete=Enabled --mfa "arn:aws:iam::account-id:mfa/root-
account-mfa-device 123789"
```

> **Note**
>
> Using MFA delete requires an approved physical or virtual authentication device. For more information about using MFA delete in Amazon S3, see Configuring MFA delete.

For more information about enabling versioning using the AWS CLI, see put-bucket-versioning in the *AWS CLI Command Reference*.

Using the AWS SDKs

The following examples enable versioning on a bucket and then retrieve versioning status using the AWS SDK for Java and the AWS SDK for .NET. For information about using other AWS SDKs, see the AWS Developer Center.

.NET

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using System;
using Amazon.S3;
using Amazon.S3.Model;

namespace s3.amazon.com.docsamples
{
    class BucketVersioningConfiguration
    {
        static string bucketName = "*** bucket name ***";

        public static void Main(string[] args)
        {
            using (var client = new AmazonS3Client(Amazon.RegionEndpoint.USEast1))
            {
                try
                {
                    EnableVersioningOnBucket(client);
                    string bucketVersioningStatus =
 RetrieveBucketVersioningConfiguration(client);
                }
                catch (AmazonS3Exception amazonS3Exception)
                {
```

```
                    if (amazonS3Exception.ErrorCode != null &&
                        (amazonS3Exception.ErrorCode.Equals("InvalidAccessKeyId")
                        ||
                        amazonS3Exception.ErrorCode.Equals("InvalidSecurity")))
                    {
                        Console.WriteLine("Check the provided AWS Credentials.");
                        Console.WriteLine(
                        "To sign up for service, go to http://aws.amazon.com/s3");
                    }
                    else
                    {
                        Console.WriteLine(
                         "Error occurred. Message:'{0}' when listing objects",
                         amazonS3Exception.Message);
                    }
                }
            }

            Console.WriteLine("Press any key to continue...");

}
```

Python

The following Python code example creates an Amazon S3 bucket, enables it for versioning, and configures a lifecycle that expires noncurrent object versions after 7 days.

```
def create_versioned_bucket(bucket_name, prefix):
    """
    Creates an Amazon S3 bucket, enables it for versioning, and configures a
 lifecycle
    that expires noncurrent object versions after 7 days.

    Adding a lifecycle configuration to a versioned bucket is a best practice.
    It helps prevent objects in the bucket from accumulating a large number of
    noncurrent versions, which can slow down request performance.

    Usage is shown in the usage_demo_single_object function at the end of this
 module.

    :param bucket_name: The name of the bucket to create.
    :param prefix: Identifies which objects are automatically expired under the
                   configured lifecycle rules.
    :return: The newly created bucket.
    """
    try:
        bucket = s3.create_bucket(
            Bucket=bucket_name,
            CreateBucketConfiguration={
```

```
                "LocationConstraint": s3.meta.client.meta.region_name
            },
        )
        logger.info("Created bucket %s.", bucket.name)
    except ClientError as error:
        if error.response["Error"]["Code"] == "BucketAlreadyOwnedByYou":
            logger.warning("Bucket %s already exists! Using it.", bucket_name)
            bucket = s3.Bucket(bucket_name)
        else:
            logger.exception("Couldn't create bucket %s.", bucket_name)
            raise

    try:
        bucket.Versioning().enable()
        logger.info("Enabled versioning on bucket %s.", bucket.name)
    except ClientError:
        logger.exception("Couldn't enable versioning on bucket %s.", bucket.name)
        raise

    try:
        expiration = 7
        bucket.LifecycleConfiguration().put(
            LifecycleConfiguration={
                "Rules": [
                    {

            "Couldn't configure lifecycle on bucket %s because %s. "
            "Continuing anyway.",
            bucket.name,
```

```
            error,
        )

    return bucket
```

Configuring MFA delete

When working with S3 Versioning in Amazon S3 buckets, you can optionally add another layer of security by configuring a bucket to enable *MFA (multi-factor authentication) delete*. When you do this, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket.

MFA delete requires additional authentication for either of the following operations:

- Changing the versioning state of your bucket
- Permanently deleting an object version

MFA delete requires two forms of authentication together:

- Your security credentials
- The concatenation of a valid serial number, a space, and the six-digit code displayed on an approved authentication device

MFA delete thus provides added security if, for example, your security credentials are compromised. MFA delete can help prevent accidental bucket deletions by requiring the user who initiates the delete action to prove physical possession of an MFA device with an MFA code and adding an extra layer of friction and security to the delete action.

To identify buckets that have MFA delete enabled, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Assessing your storage activity and usage with S3 Storage Lens. For a complete list of metrics, see S3 Storage Lens metrics glossary.

The bucket owner, the AWS account that created the bucket (root account), and all authorized users can enable versioning. However, only the bucket owner (root account) can enable MFA delete. For more information, see Securing Access to AWS Using MFA on the AWS Security Blog.

> **Note**
>
> To use MFA delete with versioning, you enable `MFA Delete`. However, you cannot enable `MFA Delete` using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API.
>
> For examples of using MFA delete with versioning, see the examples section in the topic Enabling versioning on buckets.
>
> You cannot use MFA delete with lifecycle configurations. For more information about lifecycle configurations and how they interact with other configurations, see How S3 Lifecycle interacts with other bucket configurations.

To enable or disable MFA delete, you use the same API that you use to configure versioning on a bucket. Amazon S3 stores the MFA delete configuration in the same *versioning* subresource that stores the bucket's versioning status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>VersioningState</Status>
  <MfaDelete>MfaDeleteState</MfaDelete>
</VersioningConfiguration>
```

To use MFA delete, you can use either a hardware or virtual MFA device to generate an authentication code. The following example shows a generated authentication code displayed on a hardware device.

MFA delete and MFA-protected API access are features intended to provide protection for different scenarios. You configure MFA delete on a bucket to help ensure that the data in your bucket cannot be accidentally deleted. MFA-protected API access is used to enforce another authentication factor (MFA code) when accessing sensitive Amazon S3 resources. You can require any operations against these Amazon S3 resources to be done with temporary credentials created using MFA. For an example, see Requiring MFA.

For more information about how to purchase and activate an authentication device, see Multi-factor authentication.

To enable S3 Versioning and configure MFA delete

Using the AWS CLI

The serial number is the number that uniquely identifies the MFA device. For physical MFA devices, this is the unique serial number that's provided with the device. For virtual MFA devices, the serial number is the device ARN. To use the following commands, replace the *`user input placeholders`* with your own information.

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a physical MFA device. For physical MFA devices, in the `--mfa` parameter, pass a concatenation of the MFA device serial number, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-
configuration Status=Enabled,MFADelete=Enabled --mfa "SerialNumber 123456"
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket for a virtual MFA device. For virtual MFA devices, in the `--mfa` parameter, pass a concatenation of the MFA device ARN, a space character, and the value that is displayed on your authentication device.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-
configuration Status=Enabled,MFADelete=Enabled --mfa "arn:aws:iam::account-id:mfa/root-
account-mfa-device 123789"
```

For more information, see the AWS rePost article How do I turn on MFA delete for my Amazon S3 bucket?.

Using the REST API

For more information about specifying MFA delete using the Amazon S3 REST API, see PutBucketVersioning *Amazon Simple Storage Service API Reference*.

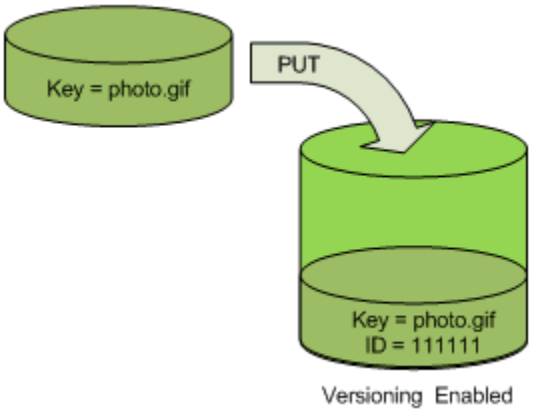
Working with objects in a versioning-enabled bucket

Objects that are stored in an Amazon S3 bucket before you set the versioning state have a version ID of `null`. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests.

Transitioning object versions

You can define lifecycle configuration rules for objects that have a well-defined lifecycle to transition object versions to the S3 Glacier Flexible Retrieval storage class at a specific time in the object's lifetime. For more information, see Managing the lifecycle of objects.

The topics in this section explain various object operations in a versioning-enabled bucket. For more information about versioning, see Retaining multiple versions of objects with S3 Versioning.



Topics

- Adding objects to versioning-enabled buckets
- Listing objects in a versioning-enabled bucket
- Retrieving object versions from a versioning-enabled bucket
- Deleting object versions from a versioning-enabled bucket
- Configuring versioned object permissions

Adding objects to versioning-enabled buckets

After you enable versioning on a bucket, Amazon S3 automatically adds a unique version ID to every object stored (using PUT, POST, or `CopyObject`) in the bucket.

The following figure shows that Amazon S3 adds a unique version ID to an object when it is added to a versioning-enabled bucket.

> **Note**
>
> The version ID values that Amazon S3 assigns are URL safe (can be included as part of a URI).

For more information about versioning, see Retaining multiple versions of objects with S3 Versioning. You can add object versions to a versioning-enabled bucket using the console, AWS SDKs, and REST API.

Using the console

For instructions, see Uploading objects.

Using the AWS SDKs

For examples of uploading objects using the AWS SDKs for Java, .NET, and PHP, see Uploading objects. The examples for uploading objects in nonversioned and versioning-enabled buckets are the same, although in the case of versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the AWS Developer Center.

Using the REST API

To add objects to versioning-enabled buckets

1. Enable versioning on a bucket using a `PutBucketVersioning` request.

For more information, see PutBucketVersioning in the *Amazon Simple Storage Service API Reference*.

2. Send a PUT, POST, or `CopyObject` request to store an object in the bucket.

When you add an object to a versioning-enabled bucket, Amazon S3 returns the version ID of the object in the `x-amz-version-id` response header, as shown in the following example.

```
x-amz-version-id: 3/L4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY
```

Listing objects in a versioning-enabled bucket

This section provides examples of listing object versions from a versioning-enabled bucket. Amazon S3 stores object version information in the *versions* subresource that is associated with the bucket. For more information, see General purpose buckets configuration options. In order to list the objects in a versioning-enabled bucket, you need the `ListBucketVersions` permission.

Using the S3 console

Follow these steps to use the Amazon S3 console to see the different versions of an object.

To see multiple versions of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. To see a list of the versions of the objects in the bucket, choose the **Show versions** switch.

   For each object version, the console shows a unique version ID, the date and time the object version was created, and other properties. (Objects stored in your bucket before you set the versioning state have a version ID of **null**.)

   To list the objects without the versions, choose the **List versions** switch.

You also can view, download, and delete object versions in the object overview pane on the console. For more information, see Viewing object properties in the Amazon S3 console.

Note

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see Retaining multiple versions of objects with S3 Versioning.

Using the AWS SDKs

The examples in this section show how to retrieve an object listing from a versioning-enabled bucket. Each request returns up to 1,000 versions, unless you specify a lower number. If the bucket contains more versions than this limit, you send a series of requests to retrieve the list of all versions. This process of returning results in "pages" is called *pagination*.

To show how pagination works, the examples limit each response to two object versions. After retrieving the first page of results, each example checks to determine whether the version list was truncated. If it was, the example continues retrieving pages until all versions have been retrieved.

Note

The following examples also work with a bucket that isn't versioning-enabled, or for objects that don't have individual versions. In those cases, Amazon S3 returns the object listing with a version ID of `null`.

For information about using other AWS SDKs, see the AWS Developer Center.

Java

For instructions on creating and testing a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```

            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

Using the REST API

Example— Listing all object versions in a bucket

To list all the versions of all the objects in a bucket, you use the `versions` subresource in a `GET Bucket` request. Amazon S3 can retrieve a maximum of 1,000 objects, and each object version counts fully as an object. Therefore, if a bucket contains two keys (for example, `photo.gif` and `picture.jpg`), and the first key has 990 versions and the second key has 400 versions, a single request would retrieve all 990 versions of `photo.gif` and only the most recent 10 versions of `picture.jpg`.

Amazon S3 returns object versions in the order in which they were stored, with the most recently stored returned first.

In a `GET Bucket` request, include the `versions` subresource.

```
GET /?versions HTTP/1.1
Host: bucketName.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 +0000
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Example— Retrieving all versions of a key

To retrieve a subset of object versions, you use the request parameters for `GET Bucket`. For more information, see GET Bucket.

1. Set the `prefix` parameter to the key of the object that you want to retrieve.
2. Send a `GET Bucket` request using the `versions` subresource and `prefix`.

```
GET /?versions&prefix=objectName HTTP/1.1
```

Example— Retrieving objects using a prefix

The following example retrieves objects whose key is or begins with `myObject`.

```
GET /?versions&prefix=myObject HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can use the other request parameters to retrieve a subset of all versions of the object. For more information, see GET Bucket in the *Amazon Simple Storage Service API Reference*.

Example— Retrieving a listing of additional objects if the response is truncated

If the number of objects that could be returned in a `GET` request exceeds the value of `max-keys`, the response contains `<isTruncated>true</isTruncated>`, and includes the first key (in `NextKeyMarker`) and the first version ID (in `NextVersionIdMarker`) that satisfy the request, but were not returned. You use those returned values as the starting position in a subsequent request to retrieve the additional objects that satisfy the `GET` request.

Use the following process to retrieve additional objects that satisfy the original `GET Bucket versions` request from a bucket. For more information about `key-marker`, `version-id-marker`, `NextKeyMarker`, and `NextVersionIdMarker`, see GET Bucket in the *Amazon Simple Storage Service API Reference*.

The following are additional responses that satisfy the original `GET` request:

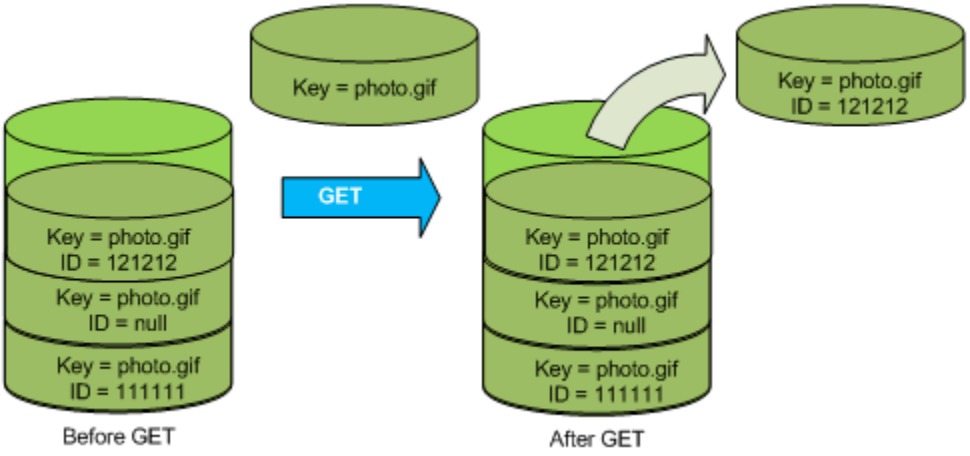
- Set the value of `key-marker` to the key returned in `NextKeyMarker` in the previous response.
- Set the value of `version-id-marker` to the version ID returned in `NextVersionIdMarker` in the previous response.
- Send a `GET Bucket versions` request using `key-marker` and `version-id-marker`.

Example— Retrieving objects starting with a specified key and version ID

```
GET /?versions&key-marker=myObject&version-id-marker=298459348571 HTTP/1.1
```

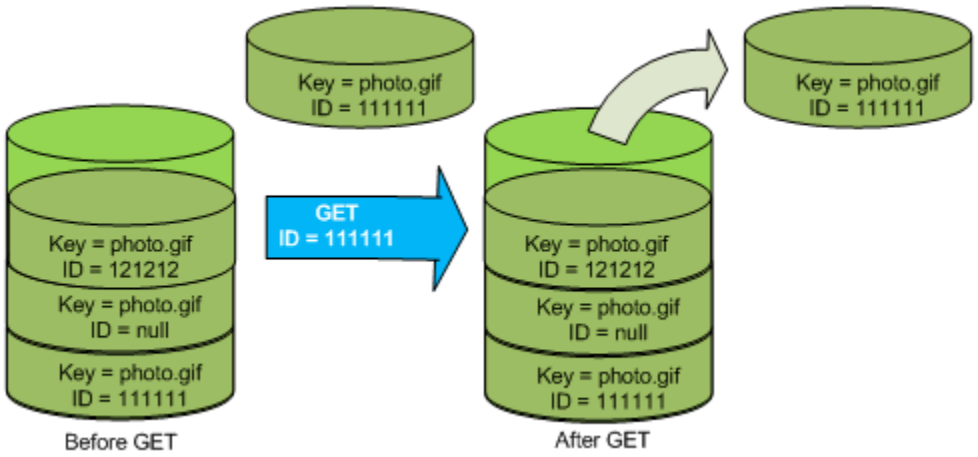
```
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Using the AWS CLI



The following command returns metadata about all versions of the objects in a bucket.

```
aws s3api list-object-versions --bucket amzn-s3-demo-bucket1
```



For more information about `list-object-versions` see list-object-versions in the *AWS CLI Command Reference*.

Retrieving object versions from a versioning-enabled bucket

Versioning in Amazon S3 is a way of keeping multiple variants of an object in the same bucket. A simple `GET` request retrieves the current version of an object. The following figure shows how `GET` returns the current version of the object, `photo.gif`.

To retrieve a specific version, you have to specify its version ID. The following figure shows that a `GET versionId` request retrieves the specified version of the object (not necessarily the current one).

You can retrieve object versions in Amazon S3 using the console, AWS SDKs, or REST API.

> **Note**
>
> To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Using the S3 console

You can restore a previous version of an object using the Amazon S3 console by deleting the current version. Deleting the current version makes the previous version the new current version.

To restore a previous version by deleting the current version

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

   Amazon S3 shows all the versions for the object.
5. Select the check box next to the **Version ID** of the current (latest) version that you want to delete.
6. Choose **Delete**.

7. In the **Delete objects** dialog box, enter **`permanently delete`**, and then choose **Delete objects**.

   After you delete the current version, the previous version becomes the current version.

To download a previous version

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

   Amazon S3 shows all the versions for the object.
5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see Viewing object properties in the Amazon S3 console.

Note

To copy a previous version in place (making it the new current version), use the AWS CLI or AWS SDKs — this approach isn't available in the Amazon S3 console. For an example, see the AWS CLI tab.

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see Retaining multiple versions of objects with S3 Versioning.

Using the AWS SDKs

The examples for uploading objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For examples of downloading objects using AWS SDKs for Java, .NET, and PHP, see Downloading objects.

For examples of listing the version of objects using AWS SDKs for .NET and Rust, see List the version of objects in an Amazon S3 bucket.

Using the REST API

To retrieve a specific object version

1. Set `versionId` to the ID of the version of the object that you want to retrieve.
2. Send a `GET Object versionId` request.

Example— Retrieving a versioned object

The following request retrieves version `L4kqtJlcpXroDTDmpUMLUo` of `my-image.jpg`.

```
GET /my-image.jpg?versionId=L4kqtJlcpXroDTDmpUMLUo HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can retrieve just the metadata of an object (not the content). For information, see the section called “Retrieving version metadata”.

For information about restoring a previous object version, see the section called “Restoring previous versions”.

Retrieving the metadata of an object version

If you only want to retrieve the metadata of an object (and not its content), you use the HEAD operation. By default, you get the metadata of the most recent version. To retrieve the metadata of a specific object version, you specify its version ID.

To retrieve the metadata of an object version

1. Set `versionId` to the ID of the version of the object whose metadata you want to retrieve.
2. Send a `HEAD Object versionId` request.

Example— Retrieving the metadata of a versioned object

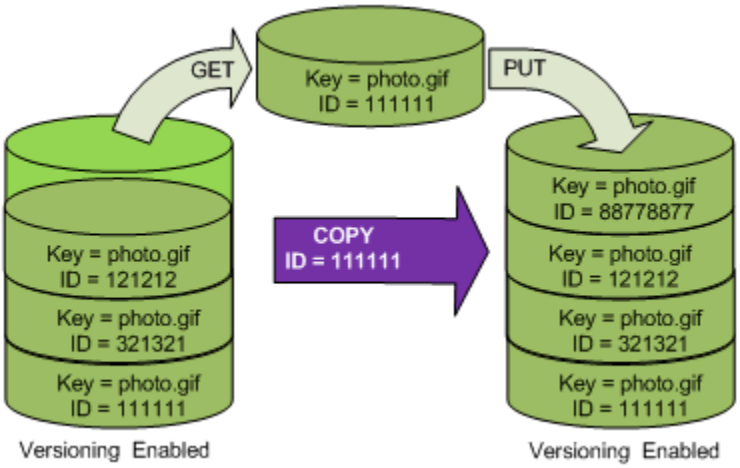
The following request retrieves the metadata of version `3HL4kqCxf3vjVBH40Nrjfkd` of `my-image.jpg`.

```
HEAD /my-image.jpg?versionId=3HL4kqCxf3vjVBH40Nrjfkd HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

The following shows a sample response.

```
HTTP/1.1 200 OK
x-amz-id-2: ef8yU9AS1ed4OpIszj7UDNEHGran
x-amz-request-id: 318BC8BC143432E5
x-amz-version-id: 3HL4kqtJlcpXroDTDmjVBH40Nrjfkd
Date: Wed, 28 Oct 2009 22:32:00 GMT
Last-Modified: Sun, 1 Jan 2006 12:00:00 GMT
ETag: "fba9dede5f27731c9771645a39863328"
Content-Length: 434234
Content-Type: text/plain
Connection: close
Server: AmazonS3
```

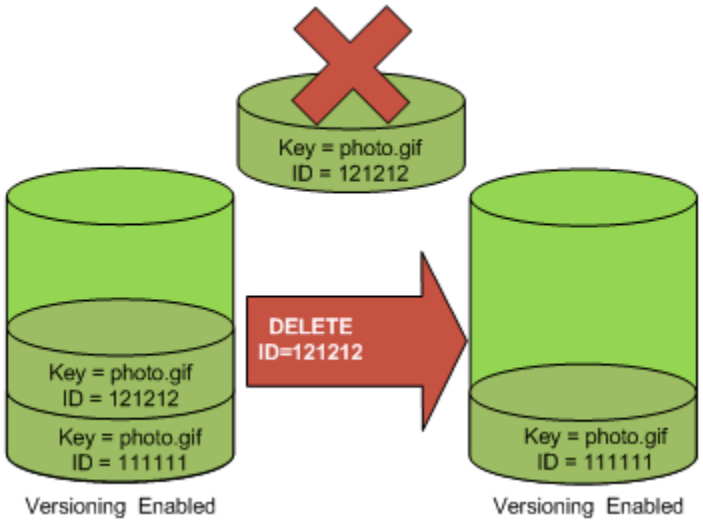
Restoring previous versions



You can use versioning to retrieve previous versions of an object. There are two approaches to doing so:

- Copy a previous version of the object into the same bucket.

  The copied object becomes the current version of that object and all object versions are preserved.
- Permanently delete the current version of the object.



When you delete the current object version, you, in effect, turn the previous version into the current version of that object.

Because all object versions are preserved, you can make any earlier version the current version by copying a specific version of the object into the same bucket. In the following figure, the source object (ID = 111111) is copied into the same bucket. Amazon S3 supplies a new ID (88778877) and it becomes the current version of the object. So, the bucket has both the original object version (111111) and its copy (88778877). For more information about getting a previous version and then uploading it to make it the current version, see Retrieving object versions from a versioning-enabled bucket and Uploading objects.

A subsequent GET retrieves version 88778877.

The following figure shows how deleting the current version (121212) of an object leaves the previous version (111111) as the current object. For more information about deleting an object, see Deleting a single object.

A subsequent GET retrieves version 111111.

> **Note**
>
> To restore object versions in batches, you can use the `CopyObject` operation. The `CopyObject` operation copies each object that is specified in the manifest. However, be aware that objects aren't necessarily copied in the same order as they appear in the manifest. For versioned buckets, if preserving current/non-current version order is important, you should copy all non-current versions first. Then, after the first job is complete, copy the current versions in a subsequent job.

To restore previous object versions

For more guidance on restoring deleted objects, see How can I retrieve an Amazon S3 object that was deleted in a versioning-enabled bucket? in the AWS re:Post Knowledge Center.

Using the S3 console

You can restore a previous version of an object using the Amazon S3 console by deleting the current version. Deleting the current version makes the previous version the new current version.

To restore a previous version by deleting the current version

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

   Amazon S3 shows all the versions for the object.
5. Select the check box next to the **Version ID** of the current (latest) version that you want to delete.
6. Choose **Delete**.
7. In the **Delete objects** dialog box, enter **`permanently delete`**, and then choose **Delete objects**.

   After you delete the current version, the previous version becomes the current version.

To download a previous version

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

   Amazon S3 shows all the versions for the object.
5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see Viewing object properties in the Amazon S3 console.

> **Note**
>
> To copy a previous version in place (making it the new current version), use the AWS CLI or AWS SDKs — this approach isn't available in the Amazon S3 console. For an example, see the AWS CLI tab.

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see Retaining multiple versions of objects with S3 Versioning.

Using the AWS CLI

To restore a previous version by copying it in place, use the `copy-object` command. For the `--copy-source` parameter, specify the version ID of the previous version that you want to restore:

```
aws s3api copy-object \
    --bucket amzn-s3-demo-bucket \
    --key my-object.jpg \
    --copy-source amzn-s3-demo-bucket/my-object.jpg?versionId=previous-version-id
```

This creates a new current version of the object with the content from the specified previous version. Amazon S3 preserves all existing versions.

Using the AWS SDKs

For information about using other AWS SDKs, see the AWS Developer Center.

Python

The following Python code example restores a versioned object's previous version by deleting all versions that occurred after the specified rollback version.

```
def rollback_object(bucket, object_key, version_id):
    """
    Rolls back an object to an earlier version by deleting all versions that
    occurred after the specified rollback version.

    Usage is shown in the usage_demo_single_object function at the end of this
 module.

    :param bucket: The bucket that holds the object to roll back.
    :param object_key: The object to roll back.
    :param version_id: The version ID to roll back to.
    """
    # Versions must be sorted by last_modified date because delete markers are
```

```
    # at the end of the list even when they are interspersed in time.
    versions = sorted(
        bucket.object_versions.filter(Prefix=object_key),
        key=attrgetter("last_modified"),
        reverse=True,
    )

    logger.debug(
        "Got versions:\n%s",
        "\n".join(
            [
                f"\t{version.version_id}, last modified {version.last_modified}"
                for version in versions
            ]
        ),
    )

    if version_id in [ver.version_id for ver in versions]:
        print(f"Rolling back to version {version_id}")
        for version in versions:
            if version.version_id != version_id:
                version.delete()
                print(f"Deleted version {version.version_id}")
            else:
                break

        print(f"Active version is now {bucket.Object(object_key).version_id}")
    else:
        raise KeyError(
            f"{version_id} was not found in the list of versions for "
f"{object_key}."
        )
```

Deleting object versions from a versioning-enabled bucket

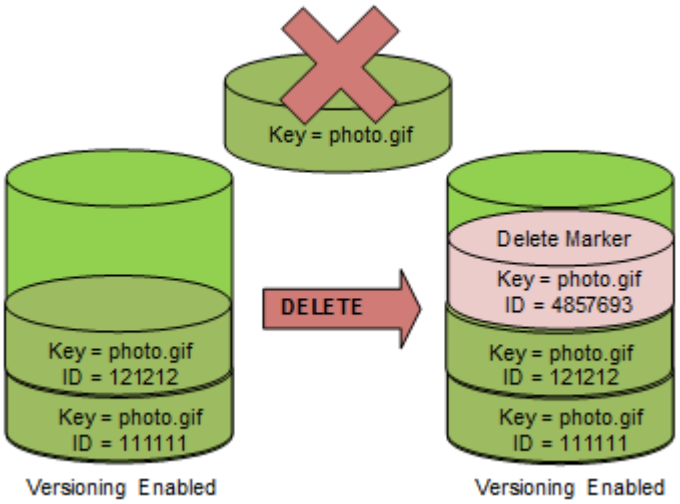
You can delete object versions from Amazon S3 buckets whenever you want. You can also define lifecycle configuration rules for objects that have a well-defined lifecycle to request Amazon S3 to expire current object versions or permanently remove noncurrent object versions. When your bucket has versioning enabled or the versioning is suspended, the lifecycle configuration actions work as follows:

- The `Expiration` action applies to the current object version. Instead of deleting the current object version, Amazon S3 retains the current version as a noncurrent version by adding a *delete marker*, which then becomes the current version.
- The `NoncurrentVersionExpiration` action applies to noncurrent object versions, and Amazon S3 permanently removes these object versions. You cannot recover permanently removed objects.

For more information about S3 Lifecycle, see Managing the lifecycle of objects and Examples of S3 Lifecycle configurations.

To see how many current and noncurrent object versions that your buckets have, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see Using S3 Storage Lens to optimize your storage costs. For a complete list of metrics, see S3 Storage Lens metrics glossary.

> **Note**
>
> Normal Amazon S3 rates apply for every version of an object that is stored and transferred, including noncurrent object versions. For more information, see Amazon S3 pricing.



Delete request use cases

A `DELETE` request has the following use cases:

- When versioning is enabled, a simple `DELETE` cannot permanently delete an object. (A simple `DELETE` request is a request that doesn't specify a version ID.) Instead, Amazon S3 inserts a delete marker in the bucket, and that marker becomes the current version of the object with a new ID.

  When you try to `GET` an object whose current version is a delete marker, Amazon S3 behaves as though the object has been deleted (even though it has not been erased) and returns a 404 error. For more information, see Working with delete markers.

  The following figure shows that a simple `DELETE` does not actually remove the specified object. Instead, Amazon S3 inserts a delete marker.

- To delete versioned objects permanently, you must use `DELETE Object versionId`.

  The following figure shows that deleting a specified object version permanently removes that object.

To delete object versions

You can delete object versions in Amazon S3 using the console, AWS SDKs, the REST API, or the AWS Command Line Interface.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that contains the object.

3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

   Amazon S3 shows all the versions for the object.
5. Select the check box next to the **Version ID** for the versions that you want to permanently delete.
6. Choose **Delete**.
7. In **Permanently delete objects?**, enter **`permanently delete`**.

   > **Warning**
   >
   > When you permanently delete an object version, the action cannot be undone.

8. Choose **Delete objects**.

   Amazon S3 deletes the object version.

Using the AWS SDKs

For examples of deleting objects using the AWS SDKs for Java, .NET, and PHP, see Deleting Amazon S3 objects. The examples for deleting objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the AWS Developer Center.

Python

The following Python code example permanently deletes a versioned object by deleting all of its versions.

```
def permanently_delete_object(bucket, object_key):
    """
    Permanently deletes a versioned object by deleting all of its versions.

    Usage is shown in the usage_demo_single_object function at the end of this
 module.

    :param bucket: The bucket that contains the object.
    :param object_key: The object to delete.
```

```
    """
    try:
        bucket.object_versions.filter(Prefix=object_key).delete()
        logger.info("Permanently deleted all versions of object %s.", object_key)
    except ClientError:
        logger.exception("Couldn't delete all versions of %s.", object_key)
        raise
```

Using the REST API

To delete a specific version of an object

- In a DELETE, specify a version ID.

Example— Deleting a specific version

The following example deletes version UIORUnfnd89493jJFJ of photo.gif.

```
DELETE /photo.gif?versionId=UIORUnfnd89493jJFJ HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
Content-Type: text/plain
Content-Length: 0
```

Using the AWS CLI

The following command deletes an object named test.txt from a bucket named *amzn-s3-demo-bucket1*. To remove a specific version of an object, you must be the bucket owner and you must use the version Id subresource.

```
aws s3api delete-object --bucket amzn-s3-demo-bucket1 --key test.txt --version-
id versionID
```

For more information about delete-object see delete-object in the *AWS CLI Command Reference*.

For more information about deleting object versions, see the following topics:

- Working with delete markers
- Removing delete markers to make an older version current
- Deleting an object from an MFA delete-enabled bucket

Working with delete markers

A *delete marker* in Amazon S3 is a placeholder (or marker) for a versioned object that was specified in a simple DELETE request. A simple DELETE request is a request that doesn't specify a version ID. Because the object is in a versioning-enabled bucket, the object is not deleted. But the delete marker makes Amazon S3 behave as if the object is deleted. You can use an Amazon S3 API DELETE call on a delete marker. To do this, you must make the DELETE request by using an AWS Identity and Access Management (IAM) user or role with the appropriate permissions.

A delete marker has a *key name* (or *key*) and version ID like any other object. However, a delete marker differs from other objects in the following ways:

- A delete marker doesn't have data associated with it.
- A delete marker isn't associated with an access control list (ACL) value.
- If you issue a GET request for a delete marker, the GET request doesn't retrieve anything because a delete marker has no data. Specifically, when your GET request doesn't specify a `versionId`, you get a 404 (Not Found) error.

Delete markers accrue a minimal charge for storage in Amazon S3. The storage size of a delete marker is equal to the size of the key name of the delete marker. A key name is a sequence of Unicode characters. The UTF-8 encoding for the key name adds 1-4 bytes of storage to your bucket for each character in the name. Delete markers are stored in the S3 Standard storage class.

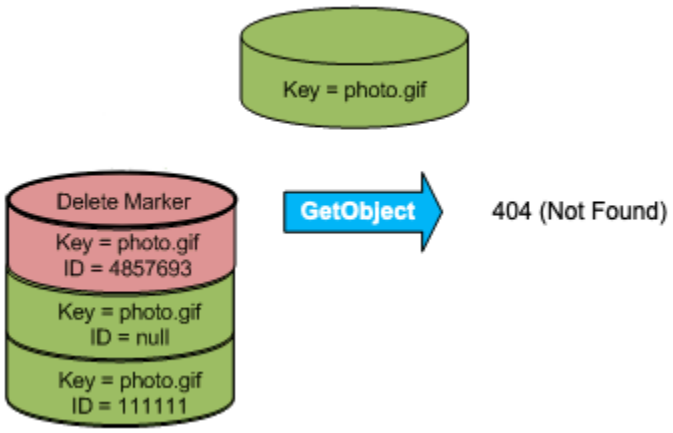
If you want to find out how many delete markers you have and what storage class they're stored in, you can use Amazon S3 Storage Lens. For more information, see Monitoring your storage activity and usage with Amazon S3 Storage Lens and Amazon S3 Storage Lens metrics glossary.

For more information about key names, see Naming Amazon S3 objects. For information about deleting a delete marker, see Managing delete markers.

Only Amazon S3 can create a delete marker, and it does so whenever you send a `DeleteObject` request on an object in a versioning-enabled or suspended bucket. The object specified in the DELETE request is not actually deleted. Instead, the delete marker becomes the current version of the object. The object's key name (or key) becomes the key of the delete marker.

When you get an object without specifying a `versionId` in your request, if its current version is a delete marker, Amazon S3 responds with the following:

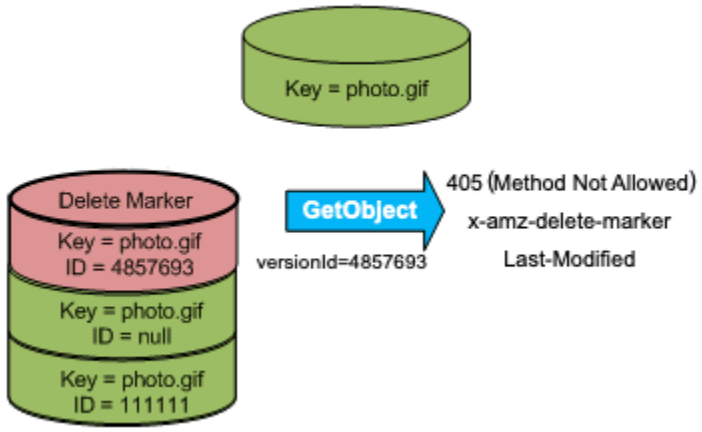
- A 404 (Not Found) error
- A response header, `x-amz-delete-marker: true`



When you get an object by specifying a `versionId` in your request, if the specified version is a delete marker, Amazon S3 responds with the following:

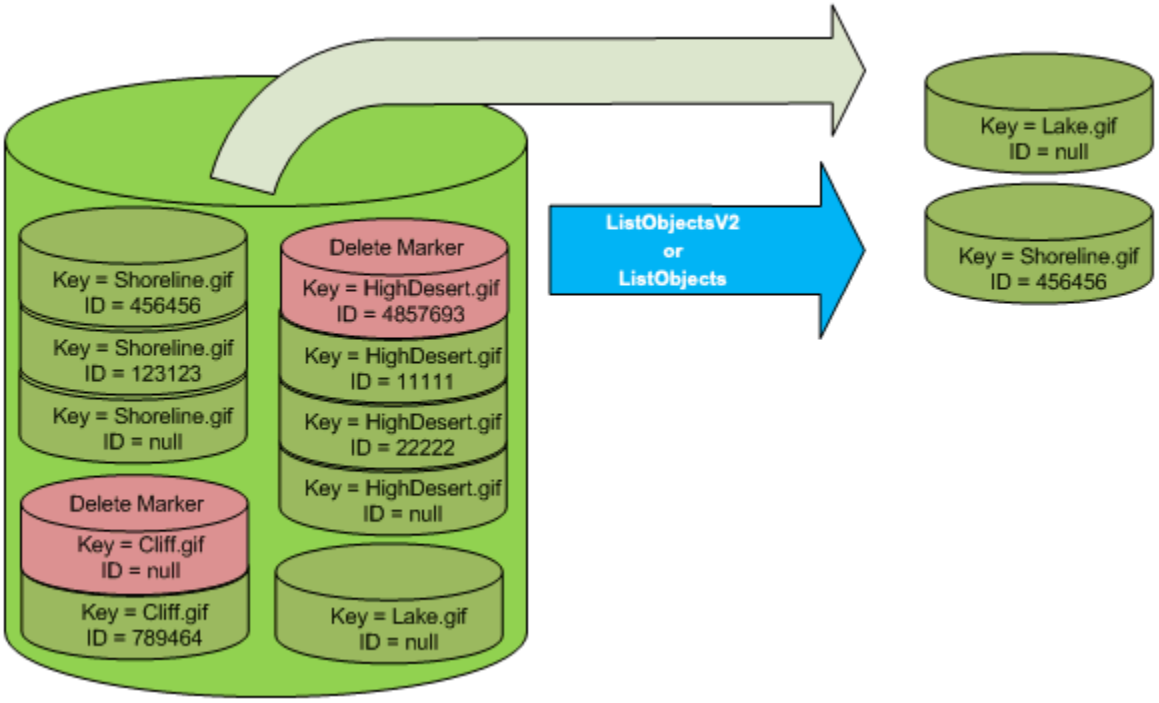
- A 405 (Method Not Allowed) error
- A response header, `x-amz-delete-marker: true`
- A response header, `Last-Modified: timestamp` (only when using the HeadObject or GetObject API operations)

The `x-amz-delete-marker: true` response header tells you that the object accessed was a delete marker. This response header never returns `false`, because when the value is `false`, the current or specified version of the object is not a delete marker.



The `Last-Modified` response header provides the creation time of the delete markers.

The following figure shows how a `GetObject` API call on an object whose current version is a delete marker responds with a 404 (Not Found) error and the response header includes `x-amz-delete-marker: true`.



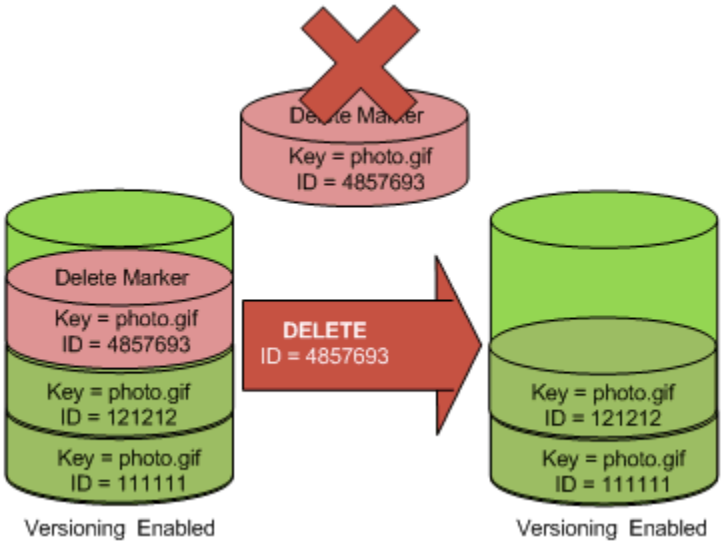
If you make a `GetObject` call on an object by specifying a `versionId` in your request, and if the specified version is a delete marker, Amazon S3 responds with a 405 (Method Not Allowed)

error and the response headers include `x-amz-delete-marker: true` and `Last-Modified: timestamp`.

Even if overwritten, delete markers remain in your object versions. The only way to list delete markers (and other versions of an object) is by using a ListObjectVersions request. You can make this request in the AWS Management Console by listing your objects in an general purpose bucket and selecting **Show versions**. For more information, see Listing objects in a versioning-enabled bucket.

The following figure shows that a ListObjectsV2 or ListObjects request doesn't return objects whose current version is a delete marker.

Managing delete markers

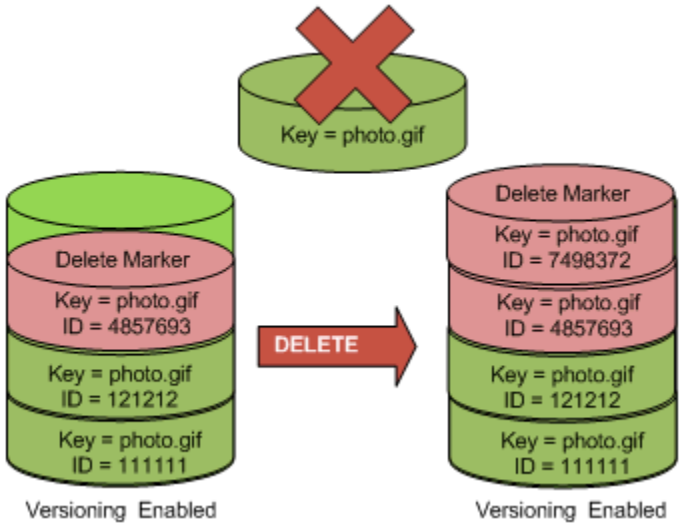


Configuring lifecycle to clean up expired delete markers automatically

An expired object delete marker is one where all object versions are deleted and only a single delete marker remains. If the lifecycle configuration is set to delete current versions, or the `ExpiredObjectDeleteMarker` action is explicitly set, Amazon S3 removes the expired object's delete marker. For an example, see Removing expired object delete markers in a versioning-enabled bucket.

Removing delete markers to make an older version current

When you delete an object in a versioning-enabled bucket, all versions remain in the bucket, and Amazon S3 creates a delete marker for the object. To undelete the object, you must delete this delete marker. For more information about versioning and delete markers, see Retaining multiple versions of objects with S3 Versioning.



To delete a delete marker permanently, you must include its version ID in a `DeleteObject versionId` request. The following figure shows how a `DeleteObject versionId` request permanently removes a delete marker.

The effect of removing the delete marker is that a simple `GET` request will now retrieve the current version ID (121212) of the object.

> **Note**
>
> If you use a `DeleteObject` request where the current version is a delete marker (without specifying the version ID of the delete marker), Amazon S3 does not delete the delete marker, but instead PUTs another delete marker.

To delete a delete marker with a `NULL` version ID, you must pass the `NULL` as the version ID in the `DeleteObject` request. The following figure shows how a simple `DeleteObject` request made without a version ID where the current version is a delete marker, removes nothing, but instead adds an additional delete marker with a unique version ID (7498372).

Using the S3 console

Use the following steps to recover deleted objects that are not folders from your S3 bucket, including objects that are within those folders.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. To see a list of the **versions** of the objects in the bucket, choose the **List versions** switch. You'll be able to see the delete markers for deleted objects.
4. To undelete an object, you must delete the delete marker. Select the check box next to the **delete marker** of the object to recover, and then choose **Delete**.
5. Confirm the deletion on the **Delete objects** page.

a. For **Permanently delete objects?** enter **`permanently delete`**.

b. Choose **Delete objects**.

> **Note**
>
> You can't use the Amazon S3 console to undelete folders. You must use the AWS CLI or SDK. For examples, see How can I retrieve an Amazon S3 object that was deleted in a versioning-enabled bucket? in the AWS Knowledge Center.

Using the REST API

To permanently remove a delete marker

1. Set `versionId` to the ID of the version to the delete marker you want to remove.
2. Send a `DELETE Object versionId` request.

Example— Removing a delete marker

The following example removes the delete marker for `photo.gif` version 4857693.

```
DELETE /photo.gif?versionId=4857693 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

When you delete a delete marker, Amazon S3 includes the following in the response.

```
204 NoContent
x-amz-version-id: versionID
x-amz-delete-marker: true
```

Using the AWS SDKs

For information about using other AWS SDKs, see the AWSDeveloper Center.

Python

The following Python code example demonstrates how to remove a delete marker from an object and thus makes the most recent non-current version, the current version of the object.

```
def revive_object(bucket, object_key):
    """
    Revives a versioned object that was deleted by removing the object's active
    delete marker.
    A versioned object presents as deleted when its latest version is a delete
 marker.
    By removing the delete marker, we make the previous version the latest version
    and the object then presents as *not* deleted.

    Usage is shown in the usage_demo_single_object function at the end of this
 module.

    :param bucket: The bucket that contains the object.
    :param object_key: The object to revive.
    """
    # Get the latest version for the object.
    response = s3.meta.client.list_object_versions(
        Bucket=bucket.name, Prefix=object_key, MaxKeys=1
    )

    if "DeleteMarkers" in response:
        latest_version = response["DeleteMarkers"][0]
        if latest_version["IsLatest"]:
            logger.info(
                "Object %s was indeed deleted on %s. Let's revive it.",
                object_key,
                latest_version["LastModified"],
            )
            obj = bucket.Object(object_key)
            obj.Version(latest_version["VersionId"]).delete()
            logger.info(
                "Revived %s, active version is now %s  with body '%s'",
                object_key,
                obj.version_id,
                obj.get()["Body"].read(),
            )
        else:
            logger.warning(
                "Delete marker is not the latest version for %s!", object_key
```

```
            )
    elif "Versions" in response:
        logger.warning("Got an active version for %s, nothing to do.", object_key)
    else:
        logger.error("Couldn't get any version info for %s.", object_key)
```

Deleting an object from an MFA delete-enabled bucket

When you configure MFA delete, only the root user can permanently delete object versions or change the versioning configuration on your S3 bucket. You must use an MFA device to authenticate the root user to perform the delete action.

If a bucket's versioning configuration is MFA delete enabled, the bucket owner must include the `x-amz-mfa` request header in requests to permanently delete an object version or change the versioning state of the bucket. Requests that include `x-amz-mfa` must use HTTPS.

The header's value is the concatenation of your authentication device's serial number, a space, and the authentication code displayed on it. If you don't include this request header, the request fails.

When using the AWS CLI include the same information as the value of the `mfa` parameter.

For more information about authentication devices, see Multi-factor Authentication.

For more information about enabling MFA delete, see Configuring MFA delete.

> **Note**
>
> Deleting an object in a versioning-enabled bucket that is MFA delete enabled is not available through the AWS Management Console.

Using the AWS CLI

To delete an object in a versioning-enabled bucket that is MFA delete enabled, use the following command. When you use the following example command, replace the *`user input placeholders`* with your own information.

```
 aws s3api delete-object --bucket amzn-s3-demo-bucket --key OBJECT-KEY --version-
id "VERSION ID" --mfa "MFA_DEVICE_SERIAL_NUMBER MFA_DEVICE_CODE"
```

Using the REST API

The following example deletes `my-image.jpg` (with the specified version), which is in a bucket configured with MFA delete enabled.

For more information, see DeleteObject in the Amazon Simple Storage Service API Reference

```
DELETE /my-image.jpg?versionId=3HL4kqCxf3vjVBH40Nrjfkd HTTPS/1.1
Host: bucketName.s3.amazonaws.com
x-amz-mfa: 20899872 301749
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Configuring versioned object permissions

Permissions for objects in Amazon S3 are set at the version level. Each version has its own object owner. The AWS account that creates the object version is the owner. So, you can set different permissions for different versions of the same object. To do so, you must specify the version ID of the object whose permissions you want to set in a PUT `Object versionId acl` request. For a detailed description and instructions on using ACLs, see Identity and Access Management for Amazon S3.

Example— Setting permissions for an object version

The following request sets the permission of the grantee with canonical user ID *b4bf1b36f9716f094c3079dcf5ac9982d4f2847de46204d47448bc557fb5ac2a*, to `FULL_CONTROL` on the key, `my-image.jpg`, version ID, `3HL4kqtJvjVBH40Nrjfkd`.

```
PUT /my-image.jpg?acl&versionId=3HL4kqtJvjVBH40Nrjfkd HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
Content-Length: 124

<AccessControlPolicy>
  <Owner>
    <ID>75cc57f09aa0c8caeab4f8c24e99d10f8e7faeebf76c078efc7c6caea54ba06a</ID>
```

```
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
        <ID>a9a7b886d6fd24a52fe8ca5bef65f89a64e0193f23000e241bf9b1c61be666e9</ID>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
  </AccessControlPolicy>
```

Likewise, to get the permissions of a specific object version, you must specify its version ID in a `GET Object versionId acl` request. You need to include the version ID because, by default, `GET Object acl` returns the permissions of the current version of the object.

Example— Retrieving the permissions for a specified object version

In the following example, Amazon S3 returns the permissions for the key, `my-image.jpg`, version ID, `DVBH40Nr8X8gUMLUo`.

```
GET /my-image.jpg?versionId=DVBH40Nr8X8gUMLUo&acl HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU
```

For more information, see GetObjectAcl in the *Amazon Simple Storage Service API Reference*.

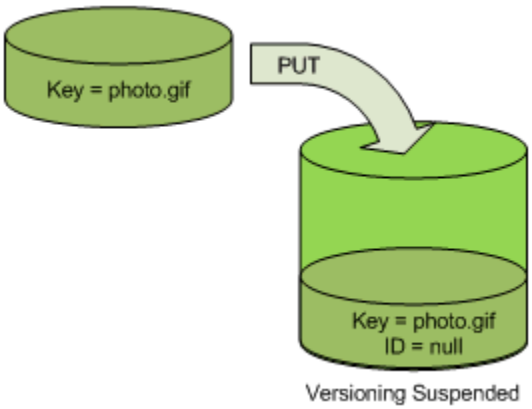
Working with objects in a versioning-suspended bucket

In Amazon S3, you can suspend versioning to stop accruing new versions of the same object in a bucket. You might do this because you only want a single version of an object in a bucket. Or, you might not want to accrue charges for multiple versions.

When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. The topics in this section explain various object operations in a versioning-suspended bucket, including adding, retrieving, and deleting objects.

For more information about S3 Versioning, see Retaining multiple versions of objects with S3 Versioning. For more information about retrieving object versions, see Retrieving object versions from a versioning-enabled bucket.

Topics

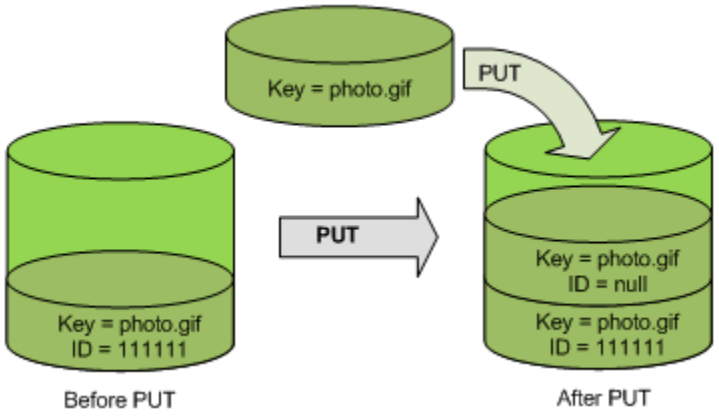


- Adding objects to versioning-suspended buckets
- Retrieving objects from versioning-suspended buckets
- Deleting objects from versioning-suspended buckets

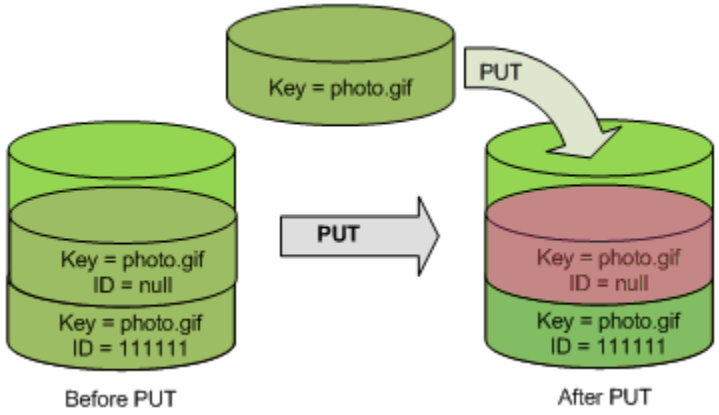
Adding objects to versioning-suspended buckets

You can add objects to versioning-suspended buckets in Amazon S3 to create the object with a null version ID or overwrite any object version with a matching version ID.

After you suspend versioning on a bucket, Amazon S3 automatically adds a `null` version ID to every subsequent object stored thereafter (using `PUT`, `POST`, or `CopyObject`) in that bucket.



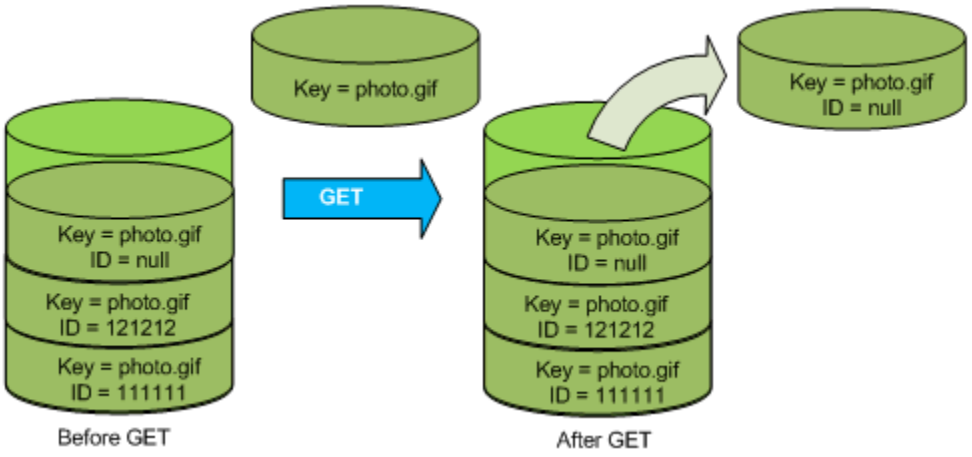
The following figure shows how Amazon S3 adds the version ID of `null` to an object when it is added to a version-suspended bucket.



If a null version is already in the bucket and you add another object with the same key, the added object overwrites the original null version.

If there are versioned objects in the bucket, the version you PUT becomes the current version of the object. The following figure shows how adding an object to a bucket that contains versioned objects does not overwrite the object already in the bucket.

In this case, version 111111 was already in the bucket. Amazon S3 attaches a version ID of null to the object being added and stores it in the bucket. Version 111111 is not overwritten.

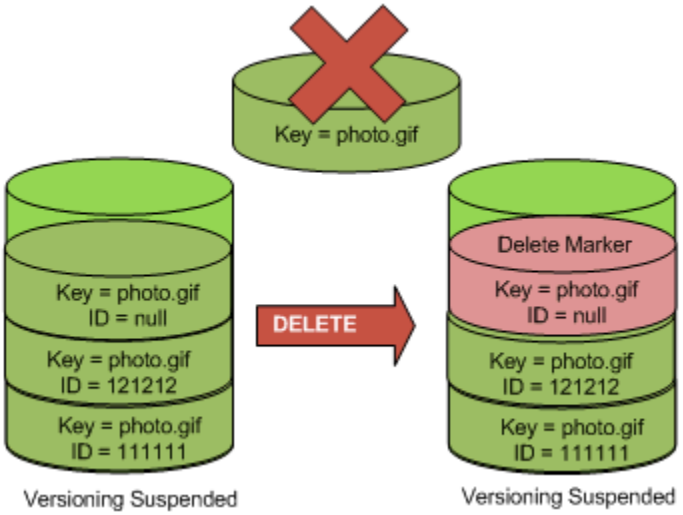


If a null version already exists in a bucket, the null version is overwritten, as shown in the following figure.

Although the key and version ID (`null`) of the null version are the same before and after the PUT, the contents of the null version originally stored in the bucket are replaced by the contents of the object PUT into the bucket.

Retrieving objects from versioning-suspended buckets

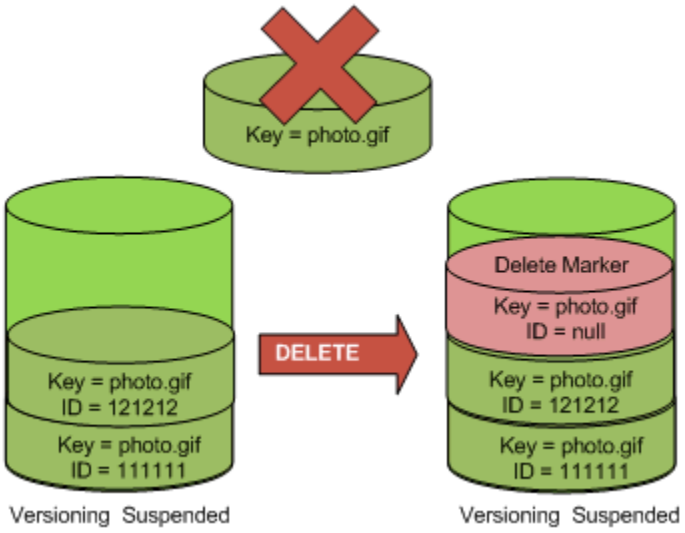
A `GET Object` request returns the current version of an object whether you've enabled versioning on a bucket or not. The following figure shows how a simple `GET` returns the current version of an object.



Deleting objects from versioning-suspended buckets

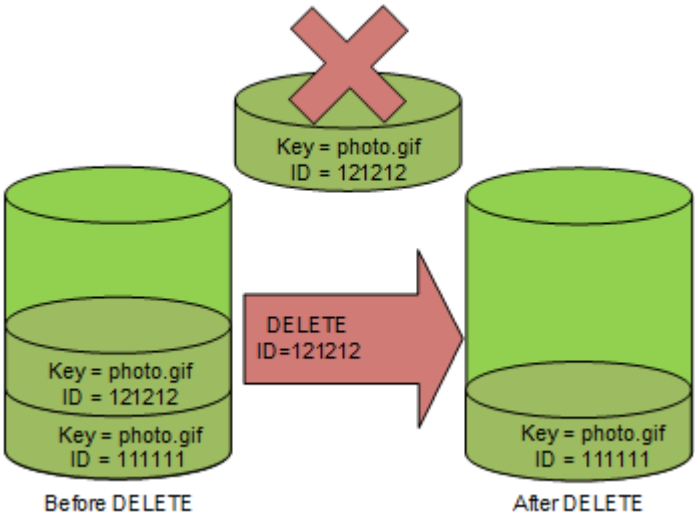
You can delete objects from versioning-suspended buckets to remove an object with a null version ID.

If versioning is suspended for a bucket, a `DELETE` request:



- Can only remove an object whose version ID is `null`.
- Doesn't remove anything if there isn't a null version of the object in the bucket.
- Inserts a delete marker into the bucket.

If bucket versioning is suspended, the operation removes the object that has a null `versionId`. If a version ID exists, Amazon S3 inserts a delete marker that becomes the current version of the object. The following figure shows how a simple `DELETE` removes a null version and Amazon S3 inserts a delete marker in its place instead with a `null` version ID.



To permanently delete an object that has a `versionId`, you must include the object's `versionId` in the request. Since a delete marker doesn't contain any content, you'll lose the content for the `null` version when a delete marker replaces it.

The following figure shows a bucket that doesn't have a null version. In this case, the `DELETE` removes nothing. Instead, Amazon S3 just inserts a delete marker.

Even in a versioning-suspended bucket, the bucket owner can permanently delete a specified version by including the version ID in the `DELETE` request, unless permissions for the `DELETE` request have been explicitly denied. For example, to deny deletion of any objects that have a `null` version ID, you must explicitly deny the `s3:DeleteObject` and `s3:DeleteObjectVersions` permissions.

The following figure shows that deleting a specified object version permanently removes that version of the object. Only the bucket owner can delete a specified object version.

Troubleshooting versioning

The following topics can help you troubleshoot some common Amazon S3 versioning issues.

Topics

- I want to recover objects that were accidentally deleted in a versioning-enabled bucket
- I want to permanently delete versioned objects
- I'm experiencing performance degradation after enabling bucket versioning

I want to recover objects that were accidentally deleted in a versioning-enabled bucket

In general, when object versions are deleted from S3 buckets, there is no way for Amazon S3 to recover them. However, if you have enabled S3 Versioning on your S3 bucket, a DELETE request that doesn't specify a version ID cannot permanently delete an object. Instead, a delete marker is added as a placeholder. This delete marker becomes the current version of the object.

To verify whether your deleted objects are permanently deleted or temporarily deleted (with a delete marker in their place), do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object.

4. In the **Objects** list, Turn on the **Show versions** toggle to the right of the search bar, and then search for the deleted object in the search bar. This toggle is available only if versioning was previously enabled on the bucket.

   You can also use S3 Inventory to search for deleted objects.
5. If you can't find the object after toggling **Show versions** or creating an inventory report, and you also cannot find a delete marker of the object, the deletion is permanent and the object cannot be recovered.

You can also verify a deleted object's status by using the `HeadObject` API operation from the AWS Command Line Interface (AWS CLI). To do so, use the following `head-object` command and replace the *`user input placeholders`* with your own information:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html
```

If you run the `head-object` command on a versioned object whose current version is a delete marker, you will receive a 404 Not Found error. For example:

An error occurred (404) when calling the HeadObject operation: Not Found

If you run the `head-object` command on a versioned object and provide the object's version ID, Amazon S3 retrieves the object's metadata, confirming that the object still exists and is not permanently deleted.

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html --
version-id versionID
```

```
{
"AcceptRanges": "bytes",
"ContentType": "text/html",
"LastModified": "Thu, 16 Apr 2015 18:19:14 GMT",
"ContentLength": 77,
"VersionId": "Zg5HyL7m.eZU9iM7AVlJkrqAiE.0UG4q",
"ETag": "\"30a6ec7e1a9ad79c203d05a589c8b400\"",
"Metadata": {}
}
```

If the object is found and the newest version is a delete marker, the previous version of the object still exists. Because the delete marker is the current version of the object, you can recover the object by deleting the delete marker.

After you permanently remove the delete marker, the second newest version of the object becomes the current version of the object, making your object available once again. For a visual depiction of how objects are recovered, see Removing delete markers.

To remove a specific version of an object, you must be the bucket owner. To delete a delete marker permanently, you must include its version ID in a `DeleteObject` request. To delete the delete marker, use the following command, and replace the *`user input placeholders`* with your own information:

```
aws s3api delete-object --bucket amzn-s3-demo-bucket --key index.html --
version-id versionID
```

For more information about the `delete-object` command, see delete-object in the *AWS CLI Command Reference*. For more information about permanently deleting delete markers, see Managing delete markers.

I want to permanently delete versioned objects

In a versioning-enabled bucket, a `DELETE` request without a version ID cannot permanently delete an object. Instead, such a request inserts a delete marker.

To permanently delete versioned objects, you can choose from the following methods:

- Create an S3 Lifecycle rule to permanently delete noncurrent versions. To permanently delete noncurrent versions, select **Permanently delete noncurrent versions of objects**, and then enter a number under **Days after objects become noncurrent**. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**. For more information about creating this rule, see Setting an S3 Lifecycle configuration.
- Delete a specified version by including the version ID in the `DELETE` request. For more information, see How to delete versioned objects permanently.
- Create a lifecycle rule to expire current versions. To expire current versions of objects, select **Expire current versions of objects**, and then add a number under **Days after object creation**. For more information about creating this lifecycle rule, see Setting an S3 Lifecycle configuration.
- To permanently delete all versioned objects and delete markers, create two lifecycle rules: one to expire current versions and permanently delete noncurrent versions of objects, and the other to delete expired object delete markers.

In a versioning-enabled bucket, a DELETE request that doesn't specify a version ID can remove only objects with a NULL version ID. If the object was uploaded when versioning was enabled, a DELETE request that doesn't specify a version ID creates a delete marker of that object.

> **Note**
>
> For S3 Object Lock-enabled buckets, a DELETE object request with a protected object version ID causes a 403 Access Denied error. A DELETE object request without a version ID adds a delete marker as the newest version of the object with a 200 OK response. Objects protected by Object Lock cannot be permanently deleted until their retention periods and legal holds are removed. For more information, see the section called “How S3 Object Lock works”.

I'm experiencing performance degradation after enabling bucket versioning

Performance degradation can occur on versioning-enabled buckets if there are too many delete markers or versioned objects, and if best practices aren't followed.

Too many delete markers

After you enable versioning on a bucket, a DELETE request without a version ID made to an object creates a delete marker with a unique version ID. Lifecycle configurations with an **Expire current versions of objects** rule add a delete marker with a unique version ID to every object. Excessive delete markers can reduce performance in the bucket.

When versioning is suspended on a bucket, Amazon S3 marks the version ID as NULL on newly created objects. An expiration action in a versioning-suspended bucket causes Amazon S3 to create a delete marker with NULL as the version ID. In a versioning-suspended bucket, a NULL delete marker is created for any delete request. These NULL delete markers are also called expired object delete markers when all object versions are deleted and only a single delete marker remains. If too many NULL delete markers accumulate, performance degradation in the bucket occurs.

Too many versioned objects

If a versioning-enabled bucket contains objects with millions of versions, an increase in 503 Service Unavailable errors can occur. If you notice a significant increase in the number of HTTP 503 Service Unavailable responses received for PUT or DELETE object requests to a versioning-enabled bucket, you might have one or more objects in the bucket with millions of versions. When you have objects with millions of versions, Amazon S3 automatically throttles requests to the bucket. Throttling

requests protects your bucket from an excessive amount of request traffic, which could potentially impede other requests made to the same bucket.

To determine which objects have millions of versions, use S3 Inventory. S3 Inventory generates a report that provides a flat file list of the objects in a bucket. For more information, see Cataloging and analyzing your data with S3 Inventory.

To verify if there are high number of versioned objects in the bucket, use S3 Storage Lens metrics to view the **Current version object count**, **Noncurrent version object count**, and **Delete marker object count**. For more information about Storage Lens metrics, see Amazon S3 Storage Lens metrics glossary.

The Amazon S3 team encourages customers to investigate applications that repeatedly overwrite the same object, potentially creating millions of versions for that object, to determine whether the application is working as intended. For instance, an application overwriting the same object every minute for a week can create over ten thousand versions. We recommend storing less than one hundred thousand versions for each object. If you have a use case that requires millions of versions for one or more objects, contact the AWS Support team for assistance with determining a better solution.

Best practices

To prevent versioning-related performance degradation issues, we recommend that you employ the following best practices:

- Enable a lifecycle rule to expire the previous versions of objects. For example, you can create a lifecycle rule to expire noncurrent versions after 30 days of the object being noncurrent. You can also retain multiple noncurrent versions if you don't want to delete all of them. For more information, see Setting an S3 Lifecycle configuration.
- Enable a lifecycle rule to delete expired object delete markers that don't have associated data objects in the bucket. For more information, see Removing expired object delete markers.

For additional Amazon S3 performance-optimization best practices, see Best practices design patterns.

Locking objects with Object Lock

S3 Object Lock can help prevent Amazon S3 objects from being deleted or overwritten for a fixed or variable amount of time, or indefinitely. Object Lock uses a *write-once-read-many* (WORM)

model to store objects. You can use Object Lock to help meet regulatory requirements that require WORM storage, or to add another layer of protection against object changes or deletion.

> **Note**
>
> S3 Object Lock has been assessed by Cohasset Associates for use in environments that are subject to SEC 17a-4, CFTC, and FINRA regulations. For more information about how Object Lock relates to these regulations, see the Cohasset Associates Compliance Assessment.

Object Lock provides two ways to manage object retention: *retention periods* and *legal holds*. An object version can have a retention period, a legal hold, or both.

- **Retention period** – A retention period specifies a fixed period of time during which an object version remains locked. S3 Object Lock provides two retention types: fixed and variable. With fixed retention, you specify the retain-until-date. With variable retention, you specify an event hold and an event hold duration, and Amazon S3 sets the retain-until-date when you release the hold. You can set a unique retention period for individual objects. Additionally, you can set a default retention period on an S3 bucket. You may also restrict the minimum and maximum allowable retention periods with the `s3:object-lock-remaining-retention-days` condition key in the bucket policy. This condition key helps you establish the allowable retention period. For more information, see Setting limits on retention periods with a bucket policy.
- **Legal hold** – A legal hold provides the same protection as a retention period, but it has no expiration date. Instead, a legal hold remains in place until you explicitly remove it. Legal holds are independent from retention periods and are placed on individual object versions.

Object Lock works only in buckets that have S3 Versioning enabled. When you lock an object version, Amazon S3 stores the lock information in the metadata for that object version. Placing a retention period or a legal hold on an object protects only the version that's specified in the request. Retention periods and legal holds don't prevent new versions of the object from being created, or delete markers to be added on top of the object. For information about S3 Versioning, see Retaining multiple versions of objects with S3 Versioning.

If you put an object into a bucket that already contains an existing protected object with the same object key name, Amazon S3 creates a new version of that object. The existing protected version of the object remains locked according to its retention configuration.

Note

Objects protected by Object Lock (both GOVERNANCE and COMPLIANCE modes) do not allow annotation modifications (create, update, or delete). The `BypassGovernanceRetention` permission does not apply to annotation operations. To add annotations to a locked object, create a new object version. The new version is not subject to the previous version's retention settings unless you explicitly apply retention to it.

How S3 Object Lock works

Topics

- Retention periods
- Retention modes
- Retain-until-date behavior with variable retention
- Legal holds
- How deletes work with S3 Object Lock
- Best practices for using S3 Object Lock
- Required permissions

Retention periods

A *retention period* protects an object version for a fixed or variable amount of time. Each retention period has a retain-until-date that indicates when the protection expires. After the retention period expires, the object version can be overwritten or deleted.

You can place a retention period explicitly on an individual object version or on a bucket's properties so that it applies to all objects in the bucket automatically. When you apply a fixed retention period to an object version explicitly, you specify a *Retain Until Date* for the object version, and Amazon S3 stores that date in the object version's metadata.

Object Lock provides two types of retention periods: *fixed* and *variable*. With fixed retention, you specify the retain-until-date when you apply the retention period. With *variable retention*, you defer the retain-until-date. You turn on an *event hold* and specify an *event hold duration*, and the

object stays protected while the event hold is on. When you release the hold, Amazon S3 sets the retain-until-date to the release time plus the duration.

You can also specify a retain-until-date with variable retention. Amazon S3 treats that date as a minimum, so the object stays protected until at least that date, even if you release the event hold earlier.

You can also set a retention period in a bucket's properties. When you set a retention period on a bucket, you specify a duration, in either days or years, for how long to protect every object version placed in the bucket. When you place an object in the bucket, Amazon S3 calculates a *Retain Until Date* for the object version by adding the specified duration to the object version's creation timestamp. The object version is then protected exactly as though you explicitly placed an individual lock with that retention period on the object version. A bucket's default retention can also turn on an event hold, so that every object version placed in the bucket starts with variable retention instead of a fixed retain-until-date.

> **Note**
>
> When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

Like all other Object Lock settings, retention periods apply to individual object versions. Different versions of a single object can have different retention modes and periods.

For example, suppose that you have an object that is 15 days into a 30-day retention period, and you PUT an object into Amazon S3 with the same name and a 60-day retention period. In this case, your PUT request succeeds, and Amazon S3 creates a new version of the object with a 60-day retention period. The older version maintains its original retention period and becomes deletable in 15 days.

After you've applied a retention setting to an object version, you can extend the retention period. To do this, submit a new Object Lock request for the object version with a *Retain Until Date* that is later than the one currently configured for the object version. Amazon S3 replaces the existing retention period with the new, longer period. Any user with permissions to place an object retention period can extend a retention period for an object version. To set a retention period, you must have the `s3:PutObjectRetention` permission.

While an event hold is on, you can also change the event hold duration. Amazon S3 does not set the retain-until-date to an earlier date than its current value.

When you set a retention period on an object or S3 bucket, you must select one of two retention modes: *compliance* or *governance*.

Retention modes

S3 Object Lock provides two retention modes that apply different levels of protection to your objects:

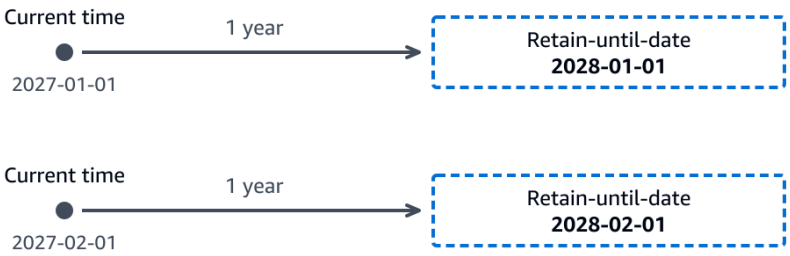
- Compliance mode
- Governance mode

In *compliance* mode, a protected object version can't be overwritten or deleted by any user, including the root user in your AWS account. When an object is locked in compliance mode, its retention mode can't be changed, and its retention period can't be shortened. Compliance mode helps ensure that an object version can't be overwritten or deleted for the duration of the retention period.

> **Note**
>
> The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

In *governance* mode, users can't overwrite or delete an object version or alter its lock settings unless they have special permissions. With governance mode, you protect objects against being deleted by most users, but you can still grant some users permission to alter the retention settings or delete the objects if necessary. You can also use governance mode to test retention-period settings before creating a compliance-mode retention period.

To override or remove governance-mode retention settings, you must have the `s3:BypassGovernanceRetention` permission and must explicitly include `x-amz-bypass-governance-retention:true` as a request header with any request that requires overriding governance mode.

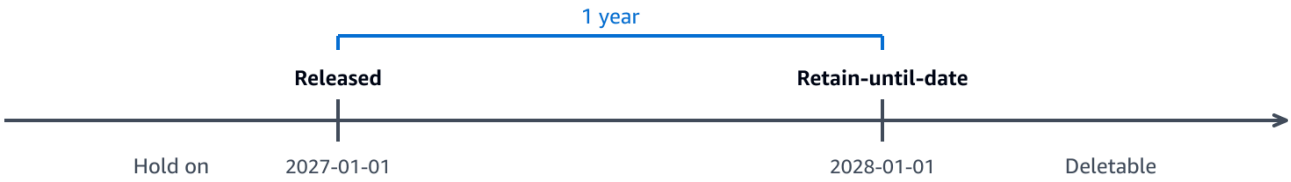


Note

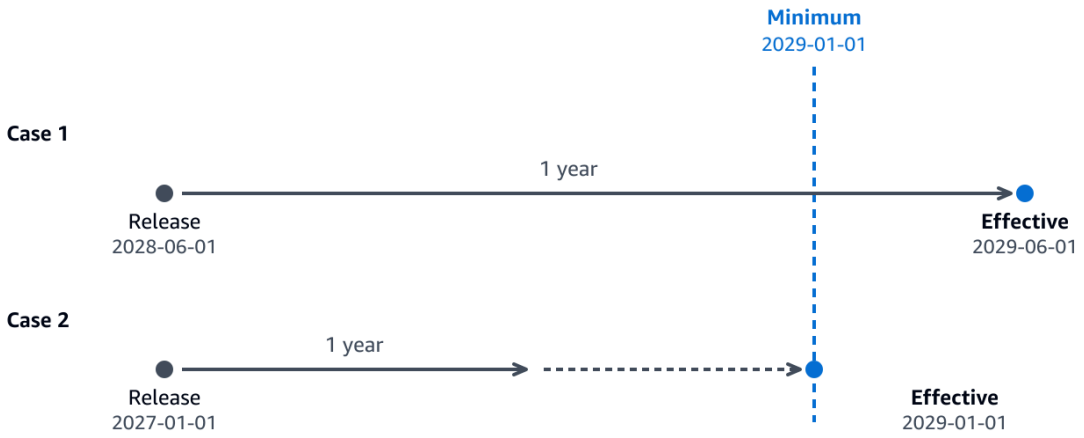
By default, the Amazon S3 console includes the `x-amz-bypass-governance-retention:true` header. If you try to delete objects protected by *governance* mode and have the `s3:BypassGovernanceRetention` permission, the operation will succeed.

Retain-until-date behavior with variable retention

The retain-until-date tells you when an object can become deletable. With fixed retention, this date doesn't change. With variable retention, Amazon S3 computes the date while the event hold is on, and fixes it when you release the hold. The following examples describe this behavior in each case.



While the event hold is on, Amazon S3 computes the retain-until-date as the current time plus the duration. The date moves forward as time passes. For example, suppose that the event hold duration is 1 year. If you retrieve the retain-until-date when the current time is `2027-01-01`, the date is `2028-01-01`. If you retrieve it again when the current time is `2027-02-01`, the date is `2028-02-01`.



You can change the event hold duration. If you decrease it, Amazon S3 does not set the retain-until-date to an earlier date than its current value. For example, suppose that a 2-year duration set the retain-until-date to `2029-01-01`. If you decrease the duration to 1 year, the computed date is `2028-01-01`, but Amazon S3 doesn't apply it. The retain-until-date remains `2029-01-01`.

When you release the event hold, Amazon S3 fixes the retain-until-date at the release time plus the duration, and the date stops changing. For example, with a 1-year duration, releasing the event hold on `2027-01-01` fixes the retain-until-date at `2028-01-01`. Until that date, the object version remains protected. After that date, you can delete it.

If you specified a retain-until-date, the effective date is the later of that minimum date and the release time plus the duration. For example, suppose that the minimum retain-until-date is `2029-01-01` and the event hold duration is 1 year. If you release the event hold on `2028-06-01`, the computed date of `2029-06-01` is later than the minimum, so Amazon S3 applies it. If you release the event hold on `2027-01-01`, the computed date of `2028-01-01` is earlier than the minimum, so Amazon S3 applies the minimum date of `2029-01-01`.

Legal holds

With Object Lock, you can also place a *legal hold* on an object version. Like a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold doesn't have an associated fixed amount of time and remains in effect until removed. Legal holds can be freely placed and removed by any user who has the `s3:PutObjectLegalHold` permission.

Legal holds are independent from retention periods. Placing a legal hold on an object version doesn't affect the retention mode or retention period for that object version.

For example, suppose that you place a legal hold on an object version and that object version is also protected by a retention period. If the retention period expires, the object doesn't lose its WORM protection. Rather, the legal hold continues to protect the object until an authorized user explicitly removes the legal hold. Similarly, if you remove a legal hold while an object version has a retention period in effect, the object version remains protected until the retention period expires.

How deletes work with S3 Object Lock

If your bucket has S3 Object Lock enabled and the object is protected by a retention period or legal hold and you try to delete an object, Amazon S3 returns one of the following responses, depending on how you tried to delete the object:

- **Permanent `DELETE` request** – If you issued a permanent `DELETE` request (a request that specifies a version ID), Amazon S3 returns an Access Denied (`403 Forbidden`) error when you try to delete the object. For more information about troubleshooting Access Denied errors with Object Lock, see the section called “S3 Object Lock settings”.

- **Simple DELETE request** – If you issued a simple DELETE request (a request that doesn't specify a version ID), Amazon S3 returns a 200 OK response and inserts a delete marker in the bucket, and that marker becomes the current version of the object with a new ID. For more information about managing delete markers with Object Lock, see the section called "Managing delete markers with Object Lock".

Best practices for using S3 Object Lock

Consider using *Governance mode* if you want to protect objects from being deleted by most users during a pre-defined retention period, but at the same time want some users with special permissions to have the flexibility to alter the retention settings or delete the objects.

Consider using *Compliance mode* if you never want any user, including the root user in your AWS account, to be able to delete the objects during a pre-defined retention period. You can use this mode in case you have a requirement to store compliant data.

You can use *Legal Hold* when you are not sure for how long you want your objects to stay immutable. This could be because you have an upcoming external audit of your data and want to keep objects immutable till the audit is complete. Alternately, you may have an ongoing project utilizing a dataset that you want to keep immutable until the project is complete.

Consider using *variable retention* when you need to protect objects but don't know the retain-until-date at write time. For example, use it when you want a configurable recovery window against ransomware or accidental deletion. You can also use it when your retention period must begin on a future business event, such as contract completion, account closure, or claim resolution.

Required permissions

Object Lock operations require specific permissions. Depending on the exact operation that you're attempting, you might need any of the following permissions:

- `s3:BypassGovernanceRetention`
- `s3:GetBucketObjectLockConfiguration`
- `s3:GetObjectLegalHold`
- `s3:GetObjectRetention`
- `s3:PutBucketObjectLockConfiguration`
- `s3:PutObjectLegalHold`
- `s3:PutObjectRetention`

For a complete list of Amazon S3 permissions with descriptions, see Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.

For information about using conditions with permissions, see Bucket policy examples using condition keys.

Object Lock considerations

Amazon S3 Object Lock can help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely.

You can use the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API to view or set Object Lock information. For general information about S3 Object Lock capabilities, see Locking objects with Object Lock.

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs. For more information, see the section called “Logging server access”.

Topics

- Permissions for viewing lock information
- Bypassing governance mode
- Using Object Lock with S3 Replication
- Using Object Lock with encryption
- Using Object Lock with Amazon S3 Inventory
- Managing S3 Lifecycle policies with Object Lock
- Managing delete markers with Object Lock
- Using S3 Storage Lens with Object Lock
- Uploading objects to an Object Lock enabled bucket

- Configuring events and notifications
- Setting limits on retention periods with a bucket policy
- Troubleshooting variable retention

Permissions for viewing lock information

You can programmatically view the Object Lock status of an Amazon S3 object version by using the HeadObject or GetObject operations. Both operations return the retention mode, retain until date, and legal hold status for the specified object version. Additionally, you can view the Object Lock status for multiple objects in your S3 bucket using S3 Inventory.

To view an object version's retention mode and retention period, you must have the `s3:GetObjectRetention` permission. To view an object version's legal hold status, you must have the `s3:GetObjectLegalHold` permission. To view a bucket's default retention configuration, you must have the `s3:GetBucketObjectLockConfiguration` permission. If you make a request for an Object Lock configuration on a bucket that doesn't have S3 Object Lock enabled, Amazon S3 returns an error. For information about setting a bucket default, see Configuring S3 Object Lock.

Bypassing governance mode

If you have the `s3:BypassGovernanceRetention` permission, you can perform operations on object versions that are locked in governance mode as if they were unprotected. These operations include deleting an object version, shortening the retention period, or removing the Object Lock retention period by placing a new `PutObjectRetention` request with empty parameters.

To bypass governance mode, you must explicitly indicate in your request that you want to bypass this mode. To do this, include the `x-amz-bypass-governance-retention:true` header with your `PutObjectRetention` API operation request, or use the equivalent parameter with requests made through the AWS CLI or AWS SDKs. The S3 console automatically applies this header for requests made through the S3 console if you have the `s3:BypassGovernanceRetention` permission.

> **Note**
>
> Bypassing governance mode doesn't affect an object version's legal hold status. If an object version has a legal hold enabled, the legal hold remains and prevents requests to overwrite or delete the object version.

Using Object Lock with S3 Replication

You can use Object Lock with S3 Replication to enable automatic, asynchronous copying of locked objects and their retention metadata, across S3 buckets. This means that for replicated objects, Amazon S3 takes the object lock configuration of the source bucket. In other words, if the source bucket has Object Lock enabled, the destination buckets must also have Object Lock enabled. If an object is directly uploaded to the destination bucket (outside of S3 Replication), it takes the Object Lock set on the destination bucket. When you use replication, objects in a *source bucket* are replicated to one or more *destination buckets*.

To set up replication on a bucket with Object Lock enabled, you can use the S3 console, AWS CLI, Amazon S3 REST API, or AWS SDKs.

> **Note**
>
> To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see Setting up permissions for live replication.
>
> For general information about S3 Replication, see Replicating objects within and across Regions.
>
> For examples of setting up S3 Replication, see Examples for configuring live replication.

Amazon S3 replicates variable retention settings—event hold and event hold duration—along with other Object Lock metadata. Both source and destination buckets must have Object Lock enabled. When an event hold is released on the source, Amazon S3 replicates the release to the destination, and the destination sets its own final retain-until-date based on the configured duration and the time of replication.

Using Object Lock with encryption

Amazon S3 encrypts all new objects by default. You can use Object Lock with your encrypted objects. For more information, see Protecting data with encryption.

While Object Lock can help prevent Amazon S3 objects from being deleted or overwritten, it does not protect against losing access to the encryption keys or encryption keys being deleted. For example, if you encrypt your objects with AWS KMS server-side encryption and your AWS KMS key is deleted your objects may become unreadable.

Using Object Lock with Amazon S3 Inventory

You can configure Amazon S3 Inventory to create lists of the objects in an S3 bucket on a defined schedule. You can configure Amazon S3 Inventory to include the following Object Lock metadata for your objects:

- The retain until date
- The retention mode
- The legal hold status
- The event hold status
- The event hold duration

While an event hold is on, the `GetObjectRetention`, `HeadObject`, and `GetObject` operations return the computed retain-until-date. If you specified a retain-until-date, the returned value is not earlier than that date.

For objects with an active event hold, Amazon S3 Inventory reports a dynamic retain-until-date based on when Amazon S3 generates the report. For objects with a released event hold or fixed retention, the retain-until-date is fixed. Inventory reports can take up to 48 hours to generate. Therefore, the retain-until-date reflects the report generation time, not the current time. For the most current value, query the object's retention metadata directly by using `GetObjectRetention`.

For more information, see Cataloging and analyzing your data with S3 Inventory.

Managing S3 Lifecycle policies with Object Lock

Object lifecycle management configurations continue to function normally on protected objects, including placing delete markers. However, a locked version of an object cannot be deleted by a S3

Lifecycle expiration policy. Object Lock is maintained regardless of which storage class the object resides in and throughout S3 Lifecycle transitions between storage classes.

For more information about managing object lifecycles, see Managing the lifecycle of objects.

Managing delete markers with Object Lock

Although you can't delete a protected object version, you can still create a delete marker for that object. Placing a delete marker on an object doesn't delete the object or its object versions. However, it makes Amazon S3 behave in most ways as though the object has been deleted. For more information, see Working with delete markers.

> **Note**
>
> Delete markers are not WORM-protected, regardless of any retention period or legal hold in place on the underlying object.

Using S3 Storage Lens with Object Lock

To see metrics for Object Lock-enabled storage bytes and object count, you can use Amazon S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity.

For more information, see Using S3 Storage Lens to protect your data.

For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

Uploading objects to an Object Lock enabled bucket

The `Content-MD5` or `x-amz-sdk-checksum-algorithm` header is required for any request to upload an object with a retention period configured using Object Lock. Theses headers are a way to verify the integrity of your object during upload.

When uploading an object with the Amazon S3 console, S3 automatically adds the `Content-MD5` header. You can optionally specify an additional checksum function and checksum value through the console as the `x-amz-sdk-checksum-algorithm` header. If you use the PutObject API you must specify the `Content-MD5` header, the `x-amz-sdk-checksum-algorithm` header, or both to configure the Object Lock retention period.

For more information, see Checking object integrity in Amazon S3.

Configuring events and notifications

You can use Amazon S3 Event Notifications to track access and changes to your Object Lock configurations and data by using AWS CloudTrail. For information about CloudTrail, see What is AWS CloudTrail? in the *AWS CloudTrail User Guide*.

You can also use Amazon CloudWatch to generate alerts based on this data. For information about CloudWatch, see the What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*.

Amazon S3 publishes an `s3:ObjectRetention:Put` event notification for explicit `PutObjectRetention` calls. This includes setting fixed or variable retention, releasing an event hold, modifying the duration, and extending a retain-until-date.

Setting limits on retention periods with a bucket policy

You can set minimum and maximum allowable retention periods for a bucket by using a bucket policy. The maximum retention period is 100 years.

The following example shows a bucket policy that uses the `s3:object-lock-remaining-retention-days` condition key to set a maximum retention period of 10 days.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "SetRetentionLimits",
    "Statement": [
        {
            "Sid": "SetRetentionPeriod",
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:PutObjectRetention"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
            "Condition": {
                "NumericGreaterThan": {
                    "s3:object-lock-remaining-retention-days": "10"
                }
```

```
            }
        }
    ]
}
```

> **Note**
>
> If your bucket is the destination bucket for a replication configuration, you can set up minimum and maximum allowable retention periods for object replicas that are created by using replication. To do so, you must allow the `s3:ReplicateObject` action in your bucket policy. For more information about replication permissions, see the section called "Setting up permissions".

For variable retention, you can control event holds and durations with the following condition keys. Amazon S3 evaluates these keys against the values in a request. They don't apply to an event hold or duration that Amazon S3 applies from a bucket's default retention configuration. For more information, see Set or modify a default variable retention period on an S3 bucket. To restrict bucket defaults, deny the `s3:PutBucketObjectLockConfiguration` action.

- `s3:object-lock-event-hold` – Restricts who can set or release event holds. Values: `ON`, `OFF`.
- `s3:object-lock-event-hold-duration-days` – Lets you enforce a minimum or maximum event hold duration, in days.

The following example denies any `PutObjectRetention` request that sets an event hold duration of less than 90 days:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RequireMinimumEventHoldDuration",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObjectRetention",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
            "Condition": {
                "NumericLessThan": {
```

```
                    "s3:object-lock-event-hold-duration-days": "90"
                }
            }
        }
    ]
}
```

The following example denies any request that sets an event hold on this bucket:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyEventHolds",
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:PutObject",
                "s3:PutObjectRetention"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
            "Condition": {
                "StringEquals": {
                    "s3:object-lock-event-hold": "ON"
                }
            }
        }
    ]
}
```

Note

A bucket policy that uses the `s3:object-lock-remaining-retention-days` condition key denies a `PutObjectRetention` request when the retention period that you specify exceeds your limit. While an event hold is active, Amazon S3 recalculates the retain-until-date on the service side. The date can move past a limit that the policy enforces at request time. If you don't want this behavior, also restrict the `s3:object-lock-event-hold` condition key to control who can enable event holds.

For more information about bucket policies, see the following topics:

- Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*

  For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.
- Object operations
- Bucket policy examples using condition keys

Troubleshooting variable retention

Use the following information to diagnose and resolve common issues with variable retention and event holds.

Request that sets an event hold is rejected

A request that sets or modifies an event hold fails with a `400 Bad Request` response.

Common causes and actions:

- **No retention mode** – An event hold requires a retention mode. Specify either `GOVERNANCE` or `COMPLIANCE`.
- **Missing or duplicate duration** – An event hold that is set to `ON` requires exactly one event hold duration. Specify the duration in either days or years, but not both.
- **Duration specified with an event hold that is set to OFF** – Don't specify an event hold duration when you release an event hold. Amazon S3 computes the final retain-until-date from the duration that is already configured on the object version.
- **No retain-until-date with an event hold that is set to OFF** – When the event hold is off, the object version must have a retain-until-date. Amazon S3 sets this date in one of two ways. It computes the date when you release an active event hold (a transition from `ON` to `OFF`). Or, you provide an explicit retain-until-date, which is fixed retention. To protect an object with variable retention, create it with the event hold set to `ON` and a duration.
- **Duration outside the allowed range** – An event hold duration must be a positive integer, up to a maximum of 36,500 days or 100 years.

Bucket policy doesn't match a duration that is set in years

There is no years-based condition key. When you set a duration in years, Amazon S3 converts it to days for evaluation against the `s3:object-lock-event-hold-duration-days` condition

key. Amazon S3 counts 1 year as 365 days and doesn't count leap years. Express the limits in your bucket policy in days, and account for this conversion. For example, Amazon S3 evaluates a duration of 1 year as 365 days.

Amazon S3 Inventory report shows an outdated retain-until-date

While an event hold is active, Amazon S3 dynamically computes the retain-until-date. Amazon S3 Inventory reports are generated periodically and can be up to 48 hours old. As a result, a report might not show the current computed retain-until-date. For the current value, use `GetObjectRetention` or `HeadObject`.

Configuring S3 Object Lock

With Amazon S3 Object Lock, you can store objects in Amazon S3 general purpose buckets by using a *write-once-read-many* (WORM) model. You can use S3 Object Lock to prevent an object from being deleted or overwritten for a fixed or variable amount of time, or indefinitely. For general information about Object Lock capabilities, see Locking objects with Object Lock.

Before you lock any objects, you must enable S3 Versioning and Object Lock on a general purpose bucket. Afterward, you can set a fixed or variable retention period, a legal hold, or both.

To work with Object Lock, you must have certain permissions. For a list of the permissions related to various Object Lock operations, see the section called “Required permissions”.

> **Important**
>
> - After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
> - S3 buckets with Object Lock can't be used as destination buckets for server access logs. For more information, see the section called “Logging server access”.

Topics

- Enable Object Lock when creating a new S3 general purpose bucket
- Enable Object Lock on an existing S3 bucket
- Set or modify a legal hold on an S3 object
- Set or modify a fixed retention period on an S3 object

- Set or modify a default fixed retention period on an S3 bucket
- Set or modify a variable retention period on an S3 object
- Release an event hold on an S3 object
- Set or modify a default variable retention period on an S3 bucket

Enable Object Lock when creating a new S3 general purpose bucket

You can enable Object Lock when creating a new S3 general purpose bucket by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. Choose **Create bucket**.

   The **Create bucket** page opens.
4. For **Bucket name**, enter a name for your bucket.

   > **Note**
   >
   > After you create a bucket, you can't change its name. For more information about naming buckets, see General purpose bucket naming rules.
5. For **Region**, choose the AWS Region where you want the bucket to reside.
6. Under **Object Ownership**, choose to disable or enable access control lists (ACLs) and control ownership of objects uploaded in your bucket.
7. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.
8. Under **Bucket Versioning**, choose **Enabled**.

   Object Lock works only with versioned buckets.
9. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs that are used to categorize storage and allocate costs.
10. Under **Advanced settings**, find **Object Lock** and choose **Enable**.

You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.

11. Choose **Create bucket**.

Using the AWS CLI

The following `create-bucket` example creates a new S3 bucket named *amzn-s3-demo-bucket1* with Object Lock enabled:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket1 --object-lock-enabled-for-bucket
```

For more information and examples, see create-bucket in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to create a new S3 bucket with Object Lock enabled. For more information, see CreateBucket in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to enable Object Lock when creating a new S3 bucket with the AWS SDKs, see CreateBucket code examples in the *Amazon S3 API Reference*.

For examples of how to get the current Object Lock configuration with the AWS SDKs, see GetObjectLockConfiguration code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Enable Object Lock on an existing S3 bucket

You can enable Object Lock for an existing S3 bucket by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.

Using the S3 console

> **Note**
>
> Object Lock works only with versioned buckets.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to enable Object Lock on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Object Lock**, choose **Enable**.

   You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.
7. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on a bucket named *`amzn-s3-demo-bucket1`*:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-
lock-configuration='{ "ObjectLockEnabled": "Enabled", "Rule": { "DefaultRetention":
 { "Mode": "COMPLIANCE", "Days": 50 }}}'
```

For more information and examples, see put-object-lock-configuration in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the Amazon S3 REST API to enable Object Lock on an existing S3 bucket. For more information, see PutObjectLockConfiguration in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to enable Object Lock for an existing S3 bucket with the AWS SDKs, see PutObjectLockConfiguration code examples in the *Amazon S3 API Reference*.

For examples of how to get the current Object Lock configuration with the AWS SDKs, see GetObjectLockConfiguration code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Set or modify a legal hold on an S3 object

You can set or remove a legal hold on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

> **Important**
>
> - If you want to set a legal hold on an object, the object's bucket must already have Object Lock enabled.
> - When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

For more information, see the section called "Legal holds".

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a legal hold on.
4. In the **Objects** list, select the object that you want to set or modify a legal hold on.
5. On the **Object properties** page, find the **Object Lock legal hold** section, and choose **Edit**.
6. Choose **Enable** to set a legal hold or **Disable** to remove a legal hold.
7. Choose **Save changes**.

Using the AWS CLI

The following `put-object-legal-hold` example sets a legal hold on the object *`my-image.fs`* in the bucket named *`amzn-s3-demo-bucket1`*:

```
aws s3api put-object-legal-hold --bucket amzn-s3-demo-bucket1 --key my-image.fs --
legal-hold="Status=ON"
```

The following `put-object-legal-hold` example removes a legal hold on the object *`my-image.fs`* in the bucket named *`amzn-s3-demo-bucket1`*:

```
aws s3api put-object-legal-hold --bucket amzn-s3-demo-bucket1 --key my-image.fs --
legal-hold="Status=OFF"
```

For more information and examples, see put-object-legal-hold in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set or modify a legal hold on an object. For more information, see PutObjectLegalHold in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a legal hold on an object with the AWS SDKs, see PutObjectLegalHold code examples in the *Amazon S3 API Reference*.

For examples of how to get the current legal hold status with the AWS SDKs, see GetObjectLegalHoldConfiguration code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Set or modify a fixed retention period on an S3 object

You can set or modify a retention period on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a retention period on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see Retention periods.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a retention period on.
4. In the **Objects** list, select the object that you want to set or modify a retention period on.
5. On the **Object properties** page, find the **Object Lock retention** section, and choose **Edit**.
6. Under **Retention**, choose **Enable** to set a retention period or **Disable** to remove a retention period.
7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see Retention modes.
8. Under **Retain until date**, choose the date that you want to have the retention period end on. During this period, your object is WORM-protected and can't be overwritten or deleted. For more information, see Retention periods.
9. Choose **Save changes**.

Using the AWS CLI

The following `put-object-retention` example sets a retention period on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1* until January 1, 2025:

```
aws s3api put-object-retention --bucket amzn-s3-demo-bucket1 --key my-image.fs --
retention='{ "Mode": "GOVERNANCE", "RetainUntilDate": "2025-01-01T00:00:00" }'
```

For more information and examples, see put-object-retention in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a retention period on an object. For more information, see PutObjectRetention in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a retention period on an object with the AWS SDKs, see PutObjectRetention code examples in the *Amazon S3 API Reference*.

For examples of how to get the retention period on an object with the AWS SDKs, see GetObjectLockConfiguration code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Set or modify a default fixed retention period on an S3 bucket

You can set or modify a default retention period on an S3 bucket by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. You specify a duration, in either days or years, for how long to protect every object version placed in the bucket.

Important

- If you want to set a default retention period on a bucket, the bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see Retention periods.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.

3. In the **Buckets** list, choose the name of the bucket that you want to set or modify a default retention period on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Default retention**, choose **Enable** to set a default retention or **Disable** to remove a default retention.
7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see Retention modes.
8. Under **Default retention period**, choose the number of days or years that you want the retention period to last for. Objects placed in this bucket will be locked for this number of days or years. For more information, see Retention periods.
9. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on the bucket named *amzn-s3-demo-bucket1* by using compliance mode:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-
lock-configuration='{ "ObjectLockEnabled": "Enabled", "Rule": { "DefaultRetention":
 { "Mode": "COMPLIANCE", "Days": 50 }}}'
```

The following `put-object-lock-configuration` example removes the default retention configuration on a bucket:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-
configuration='{ "ObjectLockEnabled": "Enabled"}'
```

For more information and examples, see put-object-lock-configuration in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from

the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a default retention period on an existing S3 bucket. For more information, see PutObjectLockConfiguration in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a default retention period on an existing S3 bucket with the AWS SDKs, see PutObjectLockConfiguration code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Set or modify a variable retention period on an S3 object

You can set variable retention on an S3 object version by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. The object's bucket must already have Object Lock enabled.

You specify the event hold duration in either days or years, but not both. You can specify 1 to 36,500 days, or 1 to 100 years.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**, and choose the bucket that contains the object.
3. In the **Objects** list, choose the object.
4. On the **Object properties** page, under **S3 Object Lock retention**, choose **Edit**.
5. Choose a **Retention mode** (Compliance or Governance).
6. Under **Retention type**, choose **Variable retention with event hold**.

7. For **Event hold duration**, enter the number of days or years.
8. (Optional) To set a minimum retain-until-date, select **Set an explicit Retain until date in addition to the event hold**, and choose a **Retain until date**. The object stays protected until at least this date even if the event hold is released earlier.
9. Choose **Save changes**.

Using the AWS CLI

The following `put-object-retention` example sets variable retention with Compliance mode and a 30-day duration on the object `my-document.pdf` in the bucket named *amzn-s3-demo-bucket1*:

```
aws s3api put-object-retention \
  --bucket amzn-s3-demo-bucket1 \
  --key my-document.pdf \
  --retention '{"Mode":"COMPLIANCE","EventHold":"ON","EventHoldDuration":{"Days":30}}'
```

The following `put-object-retention` example sets variable retention with a minimum retain-until-date:

```
aws s3api put-object-retention \
  --bucket amzn-s3-demo-bucket1 \
  --key my-document.pdf \
  --retention '{"Mode":"COMPLIANCE","EventHold":"ON","EventHoldDuration":
{"Days":30},"RetainUntilDate":"2027-01-01T00:00:00Z"}'
```

The following `put-object` example sets variable retention at upload time:

```
aws s3api put-object \
  --bucket amzn-s3-demo-bucket1 \
  --key my-document.pdf \
  --body my-document.pdf \
  --object-lock-mode COMPLIANCE \
  --object-lock-event-hold ON \
  --object-lock-event-hold-duration-days 30
```

For more information and examples, see put-object-retention in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set variable retention on an object. For more information, see PutObjectRetention in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set variable retention on an object with the AWS SDKs, see PutObjectRetention code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

Release an event hold on an S3 object

You can release an event hold on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. The object's bucket must already have Object Lock enabled.

When you release an event hold, Amazon S3 sets the final retain-until-date to the release time plus the configured duration. The object remains WORM-protected for the full duration after release.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**, and choose the bucket that contains the object.
3. In the **Objects** list, choose the object.
4. On the **Object properties** page, under **S3 Object Lock retention**, choose **Edit**.
5. Under **Event hold**, choose **Turn off event hold** and confirm.

Alternatively, if you want to release the event hold and set a later retain-until-date, under **Retention type** choose **Fixed retention**, specify a retain-until-date, and choose **Save changes**.

Using the AWS CLI

The following `put-object-retention` example releases the event hold on the object `my-document.pdf`:

```
aws s3api put-object-retention \
  --bucket amzn-s3-demo-bucket1 \
  --key my-document.pdf \
  --retention '{"Mode":"COMPLIANCE","EventHold":"OFF"}'
```

For more information and examples, see put-object-retention in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to release an event hold on an object. For more information, see PutObjectRetention in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to release an event hold on an object with the AWS SDKs, see PutObjectRetention code examples in the *Amazon S3 API Reference*.

Set or modify a default variable retention period on an S3 bucket

You can set or modify a default variable retention period on an S3 bucket by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. You specify a duration, in either days or years, for how long to protect every object version placed in the bucket after the event hold is released.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set or modify a default retention period on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Default retention**, choose **Enable**.
7. Under **Retention mode**, choose either **Governance mode** or **Compliance mode**.
8. Under **Retention type**, choose **Variable retention with event hold**.
9. Under **Event hold duration**, enter the number of days or years. New objects uploaded without explicit retention settings receive this default mode, event hold, and duration.
10. (Optional) To set a minimum retention period for new objects, select **Add extra retention protection**, and enter a **Default retention period**. Each new object stays protected for at least this period, even if its event hold is released earlier.
11. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example configures a bucket default with Compliance mode, a default event hold duration of 90 days, and a default retention period of 365 days:

```
aws s3api put-object-lock-configuration \
  --bucket amzn-s3-demo-bucket1 \
  --object-lock-configuration '{
    "ObjectLockEnabled": "Enabled",
    "Rule": {
      "DefaultRetention": {
        "Mode": "COMPLIANCE",
        "Days": 365,
        "DefaultEventHold": {"Days": 90}
      }
    }
```

```
}'
```

For more information and examples, see put-object-lock-configuration in the *AWS CLI Command Reference*.

> **Note**
>
> You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see What is CloudShell? in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a default variable retention period on an existing S3 bucket. For more information, see PutObjectLockConfiguration in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a default retention period on an existing S3 bucket with the AWS SDKs, see PutObjectLockConfiguration code examples in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see Object Lock scenario code examples in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.

Backing up your Amazon S3 data

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan.

When using AWS Backup for Amazon S3, you can perform the following actions:

- Create continuous backups and periodic backups. Continuous backups are useful for point-in-time restore, and periodic backups are useful to meet your long-term data-retention needs.
- Automate backup scheduling and retention by centrally configuring backup policies.
- Restore backups of Amazon S3 data to a point in time that you specify.
- Access backup data directly through S3 access points without initiating a restore, enabling targeted file recovery, data validation, and compliance auditing.

Along with AWS Backup, you can use S3 Versioning and S3 Replication to help recover from accidental deletions and perform your own self-recovery operations.

Accessing backup data

AWS Backup lets you read Amazon S3 backup data directly through S3 access points without initiating a full restore. You create a backup access point for a specific S3 recovery point, and AWS Backup provisions an S3 access point that you can use with standard S3 read operations such as `GetObject`, `HeadObject`, and `ListObjectsV2`.

For more information, see Backup access points in the *AWS Backup Developer Guide*.

Prerequisites

You must activate S3 Versioning on your bucket before AWS Backup can back it up.

> **Note**
>
> We recommend that you set a lifecycle expiration rule for versioning-enabled buckets that are being backed up. If you do not set a lifecycle expiration period, your Amazon S3 storage costs might increase because AWS Backup retains all versions of your Amazon S3 data.

Getting started

To get started with AWS Backup for Amazon S3, see Creating Amazon S3 backups in the *AWS Backup Developer Guide*.

Restrictions and limitations

To learn about the limitations, see Creating Amazon S3 backups in the *AWS Backup Developer Guide*.

Cost optimization

Amazon S3 offers a range of features and storage classes to help you optimize costs throughout your data lifecycle. Storage classes offer the flexibility to manage your costs, by providing different data-access levels at corresponding costs, with no upfront fees or commitment to how much content you store. Like other AWS services, you pay as you go and pay only for what you use.

Amazon S3 storage classes are purpose-built to provide the lowest cost storage for different access patterns. These include:

- S3 Standard for general-purpose storage of frequently accessed data.
- Amazon S3 Express One Zone for high-performance frequently accessed data in a single-Availability Zone.
- S3 Intelligent-Tiering to automatically optimize costs for data with unknown or changing access patterns.
- S3 Standard-IA (S3 Standard-IA) and S3 One Zone-IA (S3 One Zone-IA) for long-lived, but less frequently accessed data.
- S3 Glacier Instant Retrieval for archive data that needs immediate access.
- S3 Glacier Flexible Retrieval for archive data that doesn't require immediate access but needs the flexibility to retrieve large sets of data at no cost.
- S3 Glacier Deep Archive for long-term archive and digital preservation at the lowest storage costs in the cloud.

You can move objects to the most cost-effective storage class at any time. Additionally, Amazon S3 provides features to manage your data lifecycle. For example, you can use S3 Lifecycle configuration to automate transitioning objects to more cost-effective storage classes, or to automatically delete expired objects based on the rules that you define.

Features such as S3 Storage Class Analysis, cost allocation tagging, and billing and usage reports help you analyze your cost and usage patterns.

Topics

- Understanding and managing Amazon S3 storage classes
- Managing the lifecycle of objects

Billing and usage reporting for Amazon S3

When using Amazon S3, you don't have to pay any upfront fees or commit to how much content you'll store. Like other AWS services, you pay as you go and pay only for what you use.

AWS provides the following reports for Amazon S3:

- **Billing reports** – Multiple reports that provide high-level views of all of the activity for the AWS services that you're using, including Amazon S3. AWS always bills the owner of the S3 bucket for Amazon S3 fees, unless the bucket was created as a Requester Pays bucket. For more information about Requester Pays, see Using Requester Pays general purpose buckets for storage transfers and usage. For more information about billing reports, see AWS Billing reports for Amazon S3.
- **Usage report** – A summary of activity for a specific service, aggregated by hour, day, or month. You can choose which usage type and operation to include. You can also choose how the data is aggregated. For more information, see AWS usage reports for Amazon S3.

The following topics provide information about billing and usage reporting for Amazon S3.

Topics

- Using cost allocation S3 bucket tags
- AWS Billing reports for Amazon S3
- AWS usage reports for Amazon S3
- Understanding your AWS billing and usage reports for Amazon S3
- Billing for Amazon S3 error responses

Using cost allocation S3 bucket tags

To track the storage cost or other criteria for individual projects or groups of projects, label your Amazon S3 buckets using cost allocation tags. A *cost allocation tag* is a key-value pair that you associate with an S3 bucket. After you activate cost allocation tags, AWS uses the tags to organize your resource costs on your cost allocation report. Cost allocation tags can only be used to label buckets. For information about tags used for labeling objects, see Tagging your objects.

The *cost allocation report* lists the AWS usage for your account by product category and linked account user. The report contains the same line items as the detailed billing report (see

Understanding your AWS billing and usage reports for Amazon S3) and additional columns for your tag keys.

AWS provides two types of cost allocation tags, an AWS-generated tag and user-defined tags. AWS defines, creates, and applies the AWS-generated `createdBy` tag for you after an Amazon S3 CreateBucket event. You define, create, and apply *user-defined* tags to your S3 bucket.

You must activate both types of tags separately in the Billing and Cost Management console before they can appear in your billing reports. For more information about AWS-generated tags, see AWS-Generated Cost Allocation Tags.

For more information about activating tags, see Using cost allocation tags in the *AWS Billing User Guide*.

User-defined cost allocation tags

A user-defined cost allocation tag has the following components:

- The tag key. The tag key is the name of the tag. For example, in the tag project/Trinity, project is the key. The tag key is a case-sensitive string that can contain 1 to 128 Unicode characters.

- The tag value. The tag value is a required string. For example, in the tag project/Trinity, Trinity is the value. The tag value is a case-sensitive string that can contain from 0 to 256 Unicode characters.

For details on the allowed characters for user-defined tags and other restrictions, see User-Defined Tag Restrictions in the *AWS Billing User Guide*. For more information about user-defined tags, see User-Defined Cost Allocation Tags in the *AWS Billing User Guide*.

S3 bucket tags

Each S3 bucket has a tag set. A *tag set* contains all of the tags that are assigned to that bucket. A tag set can contain as many as 50 tags, or it can be empty. Keys must be unique within a tag set, but values in a tag set don't have to be unique. For example, you can have the same value in tag sets named project/Trinity and cost-center/Trinity.

Within a bucket, if you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS doesn't apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, edit, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

Managing tags for general purpose buckets

You can add or manage tags for general purpose buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs. For more information, see the following.

Using the Amazon S3 Console

To create tags in the console, see:

- Viewing the properties for an S3 general purpose bucket.

Using the API

To manage tags using the Amazon S3 API, see the following API pages in the *Amazon Simple Storage Service API Reference*.

- PutBucketTagging
- GetBucketTagging
- DeleteBucketTagging

> **Note**
>
> After you enable ABAC, the `PutBucketTagging` or `DeleteBucketTagging` operations will no longer work. Instead, use the `TagResource` and `UntagResource` APIs to add or delete tags on your buckets. We recommend you use the `TagResource` and `UntagResource` APIs to manage tagging before enabling ABAC on your buckets. To learn more about ABAC, seeEnabling ABAC in general purpose buckets.

Using the CLI

To manage tags using the AWS CLI, see the following pages in the AWS CLI Command Reference.

- put-bucket-tagging
- get-bucket-tagging
- delete-bucket-tagging

- AWS Billing reports for Amazon S3

AWS Billing reports for Amazon S3

Your monthly bill from AWS separates your usage information and cost by AWS service and function. There are several AWS Billing reports available: the monthly report, the cost allocation report, and detailed billing reports. For information about how to see your billing reports, see Viewing Your Bill in the *AWS Billing User Guide*.

To track your AWS usage and provide estimated charges associated with your account, you can set up AWS Cost and Usage Reports. For more information, see What are AWSCost and Usage Reports? in the *AWS Data Exports Guide*.

You can also download a usage report that gives more detail about your Amazon S3 storage usage than the billing reports. For more information, see AWS usage reports for Amazon S3.

The following table lists the charges associated with Amazon S3 usage.

Charge	Comments
Storage	You pay for storing objects in your S3 buckets. The rate you're charged depends on your objects' size, how long you stored the objects during the month, and the storage class. Amazon S3 offers the following storage classes: S3 Standard, S3 Express One Zone, S3 Intelligent-Tiering, S3 Standard-IA (IA for infrequent access), S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible

Charge	Comments
	Retrieval, S3 Glacier Deep Archive, or Reduced Redundancy Storage (RRS). For more information about storage classes, see Understanding and managing Amazon S3 storage classes. Be aware that if you have S3 Versioning enabled, you're charged for each version of an object that is retained. For more information about versioning, see How S3 Versioning works.
General purpose buckets	You're not billed for the first 2000 general purpose buckets that you create in your account. However, there is a per-bucket rate for each bucket that you create beyond the first 2000. This rate is billed per bucket/month. For information about general purpose bucket pricing, see Amazon S3 Pricing.
Monitoring and automation	You pay a monthly monitoring and automation fee per object stored in the S3 Intelligent-Tiering storage class to monitor access patterns and move objects between access tiers in S3 Intelligent-Tiering.
Requests	You pay for requests, for example, GET requests, made against your S3 buckets and objects. This includes lifecycle requests. The rates for requests depend on what kind of request you're making. For information about request pricing, see Amazon S3 Pricing.
Retrievals	You pay for retrieving objects that are stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive storage.

Charge	Comments
Early deletes	If you delete an object stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage before the minimum storage commitment has passed, you pay an early deletion fee for that object.
Storage management	You pay for the storage management features (Amazon S3 Inventory, analytics, and object tagging) that are enabled on your account's buckets.
Bandwidth	You pay for all bandwidth into and out of Amazon S3, except for the following: • Data transferred in from the internet • Data transferred out to an Amazon Elastic Compute Cloud (Amazon EC2) instance, when the instance is in the same AWS Region as the S3 bucket • Data transferred out to Amazon CloudFront (CloudFront) You also pay a fee for any data transferred by using Amazon S3 Transfer Acceleration.

For detailed information about Amazon S3 usage charges for storage, data transfer, and services, see Amazon S3 Pricing and the Amazon S3 FAQs.

For information about understanding the codes and abbreviations used in the billing and usage reports for Amazon S3, see Understanding your AWS billing and usage reports for Amazon S3.

- Amazon S3 Pricing

AWS usage reports for Amazon S3

When you download a usage report, you can choose to aggregate usage data by hour, day, or month. The Amazon S3 usage report lists operations by usage type and AWS Region. For more detailed reports about your Amazon S3 storage usage, download dynamically generated AWS usage reports. You can choose which usage type, operation, and time period to include. You can also choose how the data is aggregated. For more information about usage reports, see AWS Usage Reportin the *AWS Data Exports User Guide*.

The Amazon S3 usage report includes the following information:

- **Service** – Amazon S3
- **Operation** – The operation performed on your bucket or object. For a detailed explanation of Amazon S3 operations, see Tracking Operations in Your Usage Reports.
- **UsageType** – One of the following values:
  - A code that identifies the type of storage
  - A code that identifies the type of request
  - A code that identifies the type of retrieval
  - A code that identifies the type of data transfer
  - A code that identifies early deletions from S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-Infrequent Access (S3 One Zone-IA), S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage
  - `StorageObjectCount` – The count of objects stored within a given bucket

  For a detailed explanation of Amazon S3 usage types, see Understanding your AWS billing and usage reports for Amazon S3.
- **Resource** – The name of the bucket or table associated with the listed usage.
- **StartTime** – Start time of the day that the usage applies to, in Coordinated Universal Time (UTC).

- **EndTime** – End time of the day that the usage applies to, in Coordinated Universal Time (UTC).
- **UsageValue** – One of the following volume values. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.
  - The number of requests during the specified time period
  - The amount of data transferred
  - The amount of data stored in a given hour
  - The amount of data associated with restorations from S3 Standard-IA, S3 One Zone-IA, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage

> **Tip**
>
> For detailed information about every request that Amazon S3 receives for your objects, turn on server access logging for your buckets. For more information, see Logging requests with server access logging.

You can download a usage report as an XML or a comma-separated values (CSV) file. The following is an example CSV usage report opened in a spreadsheet application.

Service	Operation	UsageType	Resource	StartTime	EndTime	UsageValue
AmazonS3	HeadBucket	USW2-C3DataTransfer-Out-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	15309
AmazonS3	PutObject	USW2-C3DataTransfer-In-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	19062
AmazonS3	HeadBucket	USW2-Requests-Tier2	admin-created3	6/1/2017 0:00	7/1/2017 0:00	68
AmazonS3	PutObjectForRepl	USW1-Requests-SIA-Tier1	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	178294
AmazonS3	PutObjectForRepl	USW1-USW2-AWS-In-Bytes	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	387929083
AmazonS3	GetObjectForRepl	USW2-Requests-NoCharge	admin-created3	6/1/2017 0:00	7/1/2017 0:00	108
AmazonS3	GetObjectForRepl	USW2-USW1-AWS-Out-Bytes	my-test-bucket-bash	6/1/2017 0:00	7/1/2017 0:00	387910021

For more information, see Understanding your AWS billing and usage reports for Amazon S3.

Downloading the AWS Usage Report

You can download a usage report as an XML or a CSV file.

To download the usage report

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the title bar, choose your username or account ID, and then choose **Billing and Cost Management**.
3. In the navigation pane, choose **Legacy Pages** and choose **Cost and usage reports**.
4. Under AWS Usage Report, choose **Create a Usage Report**.
5. On the **Download usage report** page, choose the following settings:
   - **Services** – Choose **Amazon Simple Storage Service**.
   - **Usage Types** – For a detailed explanation of Amazon S3 usage types, see Understanding your AWS billing and usage reports for Amazon S3.
   - **Operation** – For a detailed explanation of Amazon S3 operations, see Tracking Operations in Your Usage Reports.
   - **Time Period** – The time period that you want the report to cover.
   - **Report Granularity** – Whether you want the report to include subtotals by the hour, by the day, or by the month.
6. Choose **Download**, choose the download format (**XML Report** or **CSV Report**), and then follow the prompts to open or save the report.

Understanding your AWS billing and usage reports for Amazon S3

When you use Amazon S3, we include related codes in your AWS billing and usage reports. Reviewing these codes helps you understand your Amazon S3 costs and usage patterns. Tracking and managing your expenses is essential for optimizing your costs. For more information, see Amazon S3 pricing.

Amazon S3 billing and usage reports use codes and abbreviations. For usage types in the table that follows, replace *`region`*, *`region1`*, and *`region2`* with abbreviations from AWS Region billing codes in the *AWS Regions and Availability Zones User Guide*.

> **Note**
>
> For the US East (N. Virginia) Region, the region prefix is omitted from usage type codes. For example, it will show `TimedStorage-ByteHrs` instead of `USE1-TimedStorage-ByteHrs`.

For S3 Multi-Region Access Points usage types in the table that follows, replace *regiongroup1* and *regiongroup2* with abbreviations from this list:

- **AP:** Asia Pacific
- **AU:** Australia
- **EU:** Europe
- **IN:** India
- **NA:** North America
- **SA:** South America

Region groups are geographical groupings of several AWS Regions. For more information, see Regions and Availability Zones. For information about pricing by AWS Region, see Amazon S3 Pricing.

The first column in the following table lists usage types that appear in your billing and usage reports. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.

Usage Type	Units	Granularity	Description
region1-*region2*-AWS-In-Bytes	GB	Hourly	The amount of accelerated data transferred to *region1* from *region2*
region1-*region2*-AWS-In-Bytes-T1	GB	Hourly	The amount of T1 accelerated data transferred to *region1* from *region2*, where

Usage Type	Units	Granularity	Description
			T1 refers to CloudFront requests to points of presence (POPs) in the United States, Europe, and Japan
region1-*region2*-AWS-In-ABytes-T2	GB	Hourly	The amount of T2 accelerated data transferred to *region1* from *region2*, where T2 refers to CloudFront requests to POPs in all other AWS edge locations
region1-*region2*-AWS-In-Bytes	GB	Hourly	The amount of data transferred to *region1* from *region2*
region1-*region2*-AWS-Out-ABytes	GB	Hourly	The amount of accelerated data transferred from *region1* to *region2*
region1-*region2*-AWS-Out-ABytes-T1	GB	Hourly	The amount of T1 accelerated data transferred from *region1* to *region2*, where T1 refers to CloudFront requests to POPs in the United States, Europe, and Japan

Usage Type	Units	Granularity	Description
region1-*region2*-AWS-Out-ABytes-T2	GB	Hourly	The amount of T2 accelerated data transferred from *region1* to *region2*, where T2 refers to CloudFront requests to POPs in all other AWS edge locations
region1-*region2*-AWS-Out-Bytes	GB	Hourly	The amount of data transferred from *region1* to *region2*
region-BatchOperations-Jobs	Count	Hourly	The number of S3 Batch Operations jobs performed
region-BatchOperations-Objects	Count	Hourly	The number of object operations performed by S3 Batch Operations
region-Bulk-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Bulk S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
region-BytesDeleted-GDA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Deep Archive storage

Usage Type	Units	Granularity	Description
region-BytesDeleted-GIR	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Instant Retrieval storage.
region-BytesDeleted-GLACIER	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Flexible Retrieval storage
region-BytesDeleted-INT	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Intelligent-Tiering storage
region-BytesDeleted-RRS	GB	Monthly	The amount of data deleted by a DeleteObject operation from Reduced Redundancy Storage (RRS) storage
region-BytesDeleted-SIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard-IA storage
region-BytesDeleted-STANDARD	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard storage

Usage Type	Units	Granularity	Description
region-BytesDeleted-ZIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 One Zone-IA storage
region-C3DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from Amazon EC2 within the same AWS Region
region-C3DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to Amazon EC2 within the same AWS Region
region-CloudFront-In-Bytes	GB	Hourly	The amount of data transferred into an AWS Region from a CloudFront distribution
region-CloudFront-Out-Bytes	GB	Hourly	The amount of data transferred from an AWS Region to a CloudFront distribution
region-DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from the internet
region-DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to the internet[1]

Usage Type	Units	Granularity	Description
region-DataTransfer-Regional-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to AWS resources within the same AWS Region
region-EarlyDelete-ByteHrs	GB-Hours	Hourly	Prorated storage usage for objects deleted from, S3 Glacier Flexible Retrieval storage before the 90-day minimum commitment ended[2]
region-EarlyDelete-GDA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Glacier Deep Archive storage before the 180-day minimum commitment ended [2]
region-EarlyDelete-GIR	GB-Hours	Hourly	Prorated storage usage for objects deleted or transitioned from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.

Usage Type	Units	Granularity	Description
region-EarlyDelete-GIR-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
region-EarlyDelete-SIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Standard-IA before the 30-day minimum commitment ended[3]
region-EarlyDelete-SIA-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Standard-IA before the 30-day minimum commitment ended[3]
region-EarlyDelete-ZIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 One Zone-IA before the 30-day minimum commitment ended[3]

Usage Type	Units	Granularity	Description
region-EarlyDelete-ZIA-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 One Zone-IA before the 30-day minimum commitment ended[3]
region-Expedited-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Expedited S3 Glacier Flexible Retrieval requests
Global-Bucket-Hrs-FreeTier	Bucket	Monthly	The number of general purpose buckets in your account within the 2000 bucket account-level free tier
Global-Bucket-Hrs	Bucket	Monthly	The number of general purpose buckets in your account beyond the 2000 bucket account-level free tier
region-Inventory-Objects Listed	Objects	Hourly	The number of objects listed for an object group (objects are grouped by bucket or prefix) with an inventory list
region-Metadata-Updates	Updates	Hourly	Per update fee for updates processed by S3 Metadata

Usage Type	Units	Granularity	Description
region-Metadata-Annotation-Processed-Bytes	GB	Hourly	Data processed by the S3 Metadata annotation table
region-Monitoring-Automation-INT	Objects	Hourly	The number of unique objects monitored and auto-tiered in the S3 Intelligent-Tiering storage class
region-MRAP-Out-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).
region-MRAP-In-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).

Usage Type	Units	Granularity	Description
regiongroup1-regiongroup2- -MRAP-Out-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint from a bucket in *regiongroup1* to a client in *regiongroup2* located outside of the AWS network.
regiongroup1-regiongroup2- -MRAP-In-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint to a bucket in *regiongroup1* from a client in *regiongroup2* located outside of the AWS network.
region-OverwriteBytes-Copy-GDA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Deep Archive storage
region-OverwriteBytes-Copy-GIR	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Instant Retrieval storage.

Usage Type	Units	Granularity	Description
region-OverwriteBytes-Copy-GLACIER	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Flexible Retrieval storage
region-OverwriteBytes-Copy-INT	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Intelligent-Tiering storage
region-OverwriteBytes-Copy-RRS	GB	Monthly	The amount of data overwritten by a CopyObject operation from Reduced Redundancy Storage (RRS) storage
region-OverwriteBytes-Copy-SIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard-IA storage
region-OverwriteBytes-Copy-STANDARD	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard storage

Usage Type	Units	Granularity	Description
region-OverwriteBytes-Copy-ZIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 One Zone-IA storage
region-OverwriteBytes-Put-GDA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Deep Archive storage
region-OverwriteBytes-Put-GIR	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Instant Retrieval storage.
region-OverwriteBytes-Put-GLACIER	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Flexible Retrieval storage
region-OverwriteBytes-Put-INT	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
region-OverwriteBytes-Put-RRS	GB	Monthly	The amount of data overwritten by a PutObject operation from Reduced Redundancy Storage (RRS) storage
region-OverwriteBytes-Put-SIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard-IA storage
region-OverwriteBytes-Put-STANDARD	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard storage
region-OverwriteBytes-Put-ZIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 One Zone-IA storage

Usage Type	Units	Granularity	Description
region1-*region2*-S3RTC-In-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from *region2* to *region1* by the PutObjectReplTime , GetObjectReplTime , InitiateMultipartUploadReplTime , UploadPartReplTime , CompleteMultipartUploadReplTime , and WriteACLReplTime operations
region1-*region2*-S3RTC-Out-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from *region1* to *region2* by the PutObjectReplTime , GetObjectReplTime , InitiateMultipartUploadReplTime , UploadPartReplTime , CompleteMultipartUploadReplTime , and WriteACLReplTime operations

Usage Type	Units	Granularity	Description
region-Annotation-TimedStorage-ByteHrs	GB-Month	Daily	Storage for annotations, billed at the Amazon S3 Standard rate
region-Requests-Annotation-Tier1	Count	Hourly	The number of PUT, COPY, POST, and LIST requests for annotations (PutObjectAnnotation , ListObjectAnnotations). Billed per 1,000 requests.
region-Requests-Annotation-Tier2	Count	Hourly	The number of GET requests for annotations (GetObjectAnnotation). Billed per 1,000 requests.
region-Requests-GDA-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Deep Archive objects [6]
region-Requests-GDA-Tier2	Count	Hourly	The number of GET and HEAD requests on S3 Glacier Deep Archive objects

Usage Type	Units	Granularity	Description
region-Requests-GDA-Tier3	Count	Hourly	The number of S3 Glacier Deep Archive standard restore requests
region-Requests-GDA-Tier5	Count	Hourly	The number of Bulk S3 Glacier Deep Archive restore requests
region-Requests-GIR-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Glacier Instant Retrieval objects.
region-Requests-GIR-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval-Tier1 requests on S3 Glacier Instant Retrieval objects.
region-Requests-GLACIER-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Flexible Retrieval objects [6]
region-Requests-GLACIER-Tier2	Count	Hourly	The number of GET and all other requests not listed on S3 Glacier Flexible Retrieval objects

Usage Type	Units	Granularity	Description
region-Requests-INT-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Intelligent-Tiering objects
region-Requests-INT-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests for S3 Intelligent-Tiering objects
region-Requests-SIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Standard-IA objects
region-Requests-SIA-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval-Tier1 requests on S3 Standard-IA objects
region-Requests-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests for S3 Standard, RRS, and tags, plus LIST requests for all buckets and objects
region-Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests

Usage Type	Units	Granularity	Description
region-Requests-Tier3	Count	Hourly	The number of lifecycle requests to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive and standard S3 Glacier Flexible Retrieval restore requests
region-Requests-Tier4	Count	Hourly	The number of lifecycle transitions to S3 Glacier Instant Retrieval, S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage
region-Requests-Tier5	Count	Hourly	The number of Bulk S3 Glacier Flexible Retrieval restore requests
region-Requests-Tier6	Count	Hourly	The number of Expedited S3 Glacier Flexible Retrieval restore requests
region-Requests-Tier8	Count	Hourly	The number of S3 Access Grants requests
region-Requests-XZ-Tier1	Count	Hourly	The number of PUT or COPY requests on S3 Express One Zone objects

Usage Type	Units	Granularity	Description
region-Requests-XZ-Tier2	Count	Hourly	The number of GET and all other non-S3 Express One Zone-Tier1 requests on S3 Express One Zone objects
region-Requests-ZIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 One Zone-IA objects
region-Requests-ZIA-Tier2	Count	Hourly	The number of GET and all other non-S3 One Zone-IA-Tier1 requests on S3 One Zone-IA objects
region-Retrieval-GIR	GB	Hourly	The amount of data retrieved from S3 Glacier Instant Retrieval storage.
region-Retrieval-SIA	GB	Hourly	The amount of data retrieved from S3 Standard-IA storage
region-Retrieval-XZ	GB	Hourly	The portion of the data that exceeds 512 KB in a given retrieval request (PUT or COPY) with S3 Express One Zone storage
region-Retrieval-ZIA	GB	Hourly	The amount of data retrieved from S3 One Zone-IA storage

Usage Type	Units	Granularity	Description
region-S3DSSE-In-Bytes	GB	Monthly	The amount of data dual-encrypted by Amazon S3
region-S3DSSE-Out-Bytes	GB	Monthly	The amount of dual-encrypted data decrypted by Amazon S3
region-S3G-DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 to restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage
region-S3G-DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to transition objects to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage
region-Select-Returned-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard storage
region-Select-Returned-GIR-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Glacier Instant Retrieval storage.

Usage Type	Units	Granularity	Description
region-Select-Returned-INT-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Intelligent-Tiering storage
region-Select-Returned-SIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard-IA storage
region-Select-Returned-ZIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 One Zone-IA storage
region-Select-Scanned-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard storage
region-Select-Scanned-GIR-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Glacier Instant Retrieval storage.
region-Select-Scanned-INT-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
region-Select-Scanned-SIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard-IA storage
region-Select-Scanned-ZIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 One Zone-IA storage
region-Standard-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with standard S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
region-StorageAnalytics-ObjCount	Objects	Hourly	The number of unique objects monitored in each Storage Class Analysis configuration.
region-StorageLens-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens advanced metrics and recommendations.
region-StorageLensFreeTier-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens usage metrics.

Usage Type	Units	Granularity	Description
StorageObjectCount	Count	Daily	The number of objects stored within a given bucket
region-Tables-CompactedObjects	Objects	Hourly	The number of objects compacted in Amazon S3 table buckets using the binpack compaction strategy in an Amazon S3 Tables compaction job.
region-Tables-SortCompactedObjects-	Objects	Hourly	The number of objects compacted in Amazon S3 table buckets using sort or z-order compaction strategies in an Amazon S3 Tables compaction job.
region-Tables-MonitoredObjects	Objects	Hourly	The number of objects in Amazon S3 table buckets
region-Tables-ProcessedBytes	GB	Hourly	The amount of data processed for compaction in Amazon S3 table buckets
region-Tables-Requests-Tier1	Count	Hourly	The number of PUT requests on Amazon S3 table buckets

Usage Type	Units	Granularity	Description
region-Tables-Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests on Amazon S3 table buckets
region-Tables-TimedStorage-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in Amazon S3 table buckets
region-TagStorage-TagHrs	Tag-Hours	Daily	The total of tags on all objects in the bucket reported by hour
region-TimedStorage-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Standard storage
region-TimedStorage-GDA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Deep Archive storage
region-TimedStorage-GDA-Staging	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Deep Archive staging storage
region-TimedStorage-GIR-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Instant Retrieval storage.

Usage Type	Units	Granularity	Description
region-TimedStorage-GIR-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 Glacier Instant Retrieval storage.
region-TimedStorage-GlacierByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Flexible Retrieval storage
region-TimedStorage-GlacierStaging	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Flexible Retrieval staging storage
region-TimedStorage-INT-FA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Frequent Access tier of S3 Intelligent-Tiering storage[5]
region-TimedStorage-INT-IA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Infrequent Access tier of S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
region-TimedStorage-INT-AA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Archive Access tier of S3 Intelligent-Tiering storage
region-TimedStorage-INT-AIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Archive Instant Access tier of S3 Intelligent-Tiering storage
region-TimedStorage-INT-DAA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Deep Archive Access tier of S3 Intelligent-Tiering storage
region-TimedStorage-RRS-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in Reduced Redundancy Storage (RRS) storage
region-TimedStorage-SIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Standard-IA storage

Usage Type	Units	Granularity	Description
region-TimedStorage-SIA-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 Standard-IA storage[4]
region-TimedStorage-XZ-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Express One Zone storage
region-TimedStorage-ZIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 One Zone-IA storage
region-TimedStorage-ZIA-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 One Zone-IA storage
region-Upload-XZ	GB	Hourly	The amount of data that exceeds 512 KB in a given upload request (PUT or COPY) with S3 Express One Zone

Notes

1. The `Global-Bucket-Hrs` and `Global-Bucket-Hrs-FreeTier` usage types apply to general purpose buckets in commercial AWS Regions and AWS GovCloud (US).
2. If you terminate a transfer before completion, the amount of data that is transferred might exceed the amount of data that your application receives. This discrepancy can occur because

a transfer termination request cannot be executed instantaneously, and some amount of data might be in transit, pending execution of the termination request. This data in transit is billed as data transferred "out."

3. For objects archived to S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes that are deleted, overwritten, or transitioned before their minimum storage commitment period (90 days for S3 Glacier Instant Retrieval and S3 Glacier Flexible Retrieval, 180 days for S3 Glacier Deep Archive), a prorated charge per gigabyte applies for the remaining days. These charges are reflected as `EarlyDelete-GIR`, `EarlyDelete-ByteHrs`, and `EarlyDelete-GDA` usage types respectively on your bill.
4. For objects that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
5. For small objects (smaller than 128 KB) that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
6. There is no minimum billable object size for objects in the S3 Intelligent-Tiering storage class. Objects that are smaller than 128 KB are not monitored or eligible for auto-tiering. Smaller objects are always stored in the S3 Intelligent-Tiering Frequent Access tier.
7. When you initiate a `CreateMultipartUpload`, `UploadPart`, or `UploadPartCopy` request to either the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, requests are billed at S3 Standard request rates until you complete the multipart upload. After the upload is completed, the single `CompleteMultipartUpload` request is billed at the PUT rate for the destination S3 Glacier storage. In-progress multipart upload parts for a PUT to the S3 Glacier Flexible Retrieval storage class are billed as S3 Glacier Flexible Retrieval Staging Storage at S3 Standard storage rates until the upload is completed. Similarly, in-progress multipart upload parts for a PUT to the S3 Glacier Deep Archive storage class are billed as S3 Glacier Deep Archive Staging Storage at S3 Standard storage rates until the upload is completed.
8. S3 Express One Zone applies a flat per-request charge for request sizes up to 512 KB. An additional per GB charge is applied for PUT requests and GET requests for the portion of request greater than 512 KB.
9. For information about supported features for S3 Express One Zone storage class, see Amazon S3 features not supported by directory buckets.
10. Usage types with units that are billed in GB are calculated in bytes in the usage reports.

11A GB-Month is derived by taking the total number of GB-hours, aggregating these over the course of a month, and then dividing by the number of hours in that month. To learn more see, Frequently Asked Questions: How will I be charged and billed for my use of Amazon S3?

> **Note**
>
> In general, S3 bucket owners are billed for requests with HTTP `200 OK` successful responses and HTTP `4XX` client error responses. Bucket owners aren't billed for HTTP `5XX` server error responses, such as HTTP `503 Slow Down` errors. For more information on S3 error codes under HTTP `3XX` and `4XX` status codes that aren't billed, see Billing for Amazon S3 error responses. For more information about billing charges if your bucket is configured as a Requester Pays bucket, see How Requester Pays charges work.

Tracking Operations in Your Usage Reports

Operations describe the action taken on your AWS object or bucket by the specified usage type. Operations are indicated by self-explanatory codes, such as `PutObject` or `ListBucket`. To see which actions on your bucket generated a specific type of usage, use these codes. When you create a usage report, you can choose to include **All Operations**, or a specific operation, for example, `GetObject`, to report on.

Billing for Amazon S3 error responses

In general, S3 bucket owners are billed for requests with HTTP `200 OK` successful responses and HTTP `4XX` client error responses. Bucket owners aren't billed for HTTP `5XX` server error responses, such as HTTP `503 Slow Down` errors. For more information about billing charges if your bucket is configured as a Requester Pays bucket, see How Requester Pays charges work.

The following table lists specific error codes under HTTP 3XX and 4XX status codes that aren't billed. For buckets configured with website hosting, applicable request and other charges will still apply when S3 returns a custom error document or for custom redirects.

> **Note**
>
> For `AccessDenied` (HTTP `403 Forbidden`), S3 doesn't charge the bucket owner when the request is initiated outside of the bucket owner's individual AWS account or the bucket owner's AWS organization.

HTTP status code	Error code	Description of error code
301 Moved Permanently	PermanentRedirect	The bucket that you are attempting to access must be addressed using the specified endpoint. Send all future requests to this endpoint.
	PermanentRedirectControlError	The API operation you are attempting to access must be addressed using the specified endpoint. Send all future requests to this endpoint.
307 Temporary Redirect	TemporaryRedirect	You are being redirected to the bucket while the Domain Name System (DNS) server is being updated.

HTTP status code	Error code	Description of error code
400 Bad Request	AuthorizationHeaderMalformed	The authorization header that you provided is not valid.
	AuthorizationQueryParametersError	The authorization query parameters that you provided are not valid.
	ConnectionClosedByRequester	Returned to the original caller when an error is encountered while reading the WriteGetObjectResponse body.
	DeviceNotActiveError	The device is not currently active.
	EndpointNotFound	Direct requests to the correct endpoint.
	ExpiredToken	The provided token has expired.
	IllegalLocationConstraintException	You are trying to access a bucket from a different Region than where the bucket exists. To avoid this error, use the `--region` option. For example: `aws s3 cp awsexample.txt s3://amzn-s3-demo-bucket/ --region ap-east-1`.

HTTP status code	Error code	Description of error code	
	InvalidArgument	This error might occur for the following reasons: • The specified argument was not valid. • The request was missing a required header. • The specified argument was incomplete or in the wrong format. • The specified argument must have a length greater than or equal to 3.	
	InvalidBucketOwnerAWSAccountID	The value of the expected bucket owner parameter must be an AWS account ID.	
	InvalidDigest	The Content-MD5 or checksum value that you specified is not valid.	

HTTP status code	Error code	Description of error code	
	InvalidEncryptionAlgorithmError	The encryption request that you specified is not valid. The valid value is AES256.	
	InvalidHostHeader	The host headers provided in the request used the incorrect style addressing.	
	InvalidHttpMethod	The request is made using an unexpected HTTP method.	

HTTP status code	Error code	Description of error code	
	InvalidRequest	This error might occur for the following reasons: • The request is using the wrong signature version. Use `AWS4-HMAC-SHA256` (Signature Version 4). • An access point can be created only for an existing bucket. • The access point is not in a state where it can be deleted. • An access point can be listed only for an existing bucket. • The next token is not valid. • At least one action must be specified in a lifecycle rule. • At least one lifecycle rule must be specified. •	

HTTP status code	Error code	Description of error code	
		The number of lifecycle rules must not exceed the allowed limit of 1000 rules. • The range for the `MaxResults` parameter is not valid. • SOAP requests must be made over an HTTPS connection. • Amazon S3 Transfer Acceleration is not supported for buckets with non-DNS compliant names. • Amazon S3 Transfer Acceleration is not supported for buckets with periods (.) in their names. • The Amazon S3 Transfer Acceleration endpoint supports only virtual style requests. • Amazon S3 Transfer Acceleration is not	

HTTP status code	Error code	Description of error code	
		configured on this bucket. • Amazon S3 Transfer Acceleration is disabled on this bucket. • Amazon S3 Transfer Acceleration is not supported on this bucket. For assistance, contact Support. • Amazon S3 Transfer Acceleration cannot be enabled on this bucket. For assistance, contact Support. • Conflicting values provided in HTTP headers and query par ameters. • Conflicting values provided in HTTP headers and POST form fields. • CopyObject request made on objects larger than 5GB in size.	

HTTP status code	Error code	Description of error code	
	InvalidSessionException	Returned if the session doesn't exist anymore because it timed out or expired.	
	InvalidSignature	The request signature that the server calculated does not match the signature that you provided. Check your AWS secret access key and signing method. For more information, see Signing and authenticating REST requests.	
	InvalidSOAPRequest	The SOAP request body is not valid.	
	InvalidStorageClass	The storage class that you specified is not valid.	
	InvalidTag	Your request contains tag input that is not valid. For example, your request might contain duplicate keys, keys or values that are too long, or system tags.	
	InvalidToken	The provided token is malformed or otherwise not valid.	

HTTP status code	Error code	Description of error code	
	InvalidURI	The specified URI couldn't be parsed.	
	KeyTooLongError	Your key is too long.	
	KMS.DisabledException	The request was rejected because the specified KMS key is not enabled.	

HTTP status code	Error code	Description of error code	
	KMS.InvalidKeyUsageException	The request was rejected for one of the following reasons: • The KeyUsage value of the KMS key is incompatible with the API operation. • The encryption algorithm or signing algorithm specified for the operation is incompatible with the type of key material in the KMS key (KeySpec). For encrypting, decrypting, re-encrypting, and generating data keys, the KeyUsage must be ENCRYPT_DECRYPT. For signing and verifying messages, the KeyUsage must be SIGN_VERIFY. For generating and verifying message authentication codes (MACs), the KeyUsage must be GENERATE_VERIFY_MAC. For deriving key agreement secrets, the KeyUsage	

HTTP status code	Error code	Description of error code	
		must be KEY_AGREEMENT. To find the KeyUsage of a KMS key, use the DescribeKey operation. To find the encryption or signing algorithms supported for a particular KMS key, use the DescribeKey operation.	

HTTP status code	Error code	Description of error code	
	KMS.KMSInvalidStateException	The request was rejected because the state of the specified resource is not valid for this request. This exception means one of the following: • The key state of the KMS key is not compatible with the operation. To find the key state, use the DescribeKey operation. For more information about which key states are compatible with each KMS operation, see Key states of AWS KMS keys in the *AWS Key Management Service Developer Guide*. • For cryptographic operations on KMS keys in custom key stores, this exception represents a general failure with many possible causes. To identify the cause, see the error message	

HTTP status code	Error code	Description of error code	
		that accompanies the exception.	
	KMS.NotFoundException	The request was rejected because the specified entity or resource could not be found.	
	LambdaInvalidResponse	Returned to the original caller when WriteGetObjectResponse responds with ValidationError to AWS Lambda. See the ValidationError message for more details. Not all cases of ValidationError result in a LambdaInvalidResponse error.	

HTTP status code	Error code	Description of error code	
	LambdaInvocationFailed	Lambda function invocation failed. Caller s might receive the following error when S3 Object Lambda is unable to successfully invoke the configure d Lambda function. The error message might contain details about an eventual error returned by the AWS Lambda service when invoking the function (for example, status code, error code, error message and request ID).	
	MalformedACLError	The ACL that you provided was not well formed or did not validate against our published schema.	
	MalformedPOSTRequest	The body of your POST request is not well-form ed multipart/form-data.	
	MalformedXML	The XML that you provided was not well formed or did not validate against our published schema.	

HTTP status code	Error code	Description of error code	
	MaxPostPreDataLengthExceededError	Your POST request fields preceding the upload file were too large.	
	MetadataTooLarge	Your metadata headers exceed the maximum allowed metadata size.	
	MissingAttachment	A SOAP attachment was expected, but none was found.	
	MissingRequestBodyError	You sent an empty XML document as a request.	
	MissingSecurityHeader	Your request is missing a required header.	
	NoLoggingStatusForKey	There is no such thing as a logging status subresource for a key.	
	NotDeviceOwnerError	The device that generated the token is not owned by the authenticated user.	
	ResponseInterrupted	Returned to the original caller when an error is encountered while reading the WriteGetObjectResponse body.	

HTTP status code	Error code	Description of error code	
	RequestHeaderSectionTooLarge	The request header and query parameters used to make the request exceed the maximum allowed sizes	
	TokenCodeInvalidError	The serial number and/or token code you provided is not valid.	
	UnexpectedContent	This request contains unsupported content.	
	UnsupportedArgument	The request contained an unsupported argument.	
	UnsupportedSignature	The provided request is signed with an unsupported STS Token version or the signature version is not supported.	
	UserKeyMustBeSpecified	The bucket POST request must contain the specified field name. If it is specified, check the order of the fields.	
	IncorrectEndpoint	The specified bucket exists in another Region. Direct requests to the correct endpoint.	

HTTP status code	Error code	Description of error code
	ValidationError	Validation errors might be returned from the WriteGetObjectResponse API operation and can occur for numerous reasons. See the error message for more details.
403 Forbidden	RequestTimeTooSkewed	The difference between the request time and the server's time is too large.
	SignatureDoesNotMatch	The request signature that the server calculated does not match the signature that you provided. Check your AWS secret access key and signing method. For more information, see REST Authentication and SOAP Authentication.
	NotSignedUp	Your account is not signed up for the Amazon S3 service. You must sign up before you can use Amazon S3. You can sign up at the following URL: https://aws.amazon.com/s3

HTTP status code	Error code	Description of error code
	InvalidSecurity	The provided security credentials are not valid.
	InvalidPayer	All access to this object has been disabled. For further assistance, see Contact Us.
	InvalidAccessKeyId	The AWS access key ID that you provided does not exist in our records.
	AccountProblem	There is a problem with your AWS account that prevents the operation from completing s uccessfully. For further assistance, see Contact Us.
	UnauthorizedAccessError	Applicable in China Regions only. Returned when a request is made to a bucket that doesn't have an ICP license. For more information, see ICP Recordal.
	UnexpectedIPError	Applicable in China Regions only. This request was rejected because the IP was unexpected.

HTTP status code	Error code	Description of error code
	MissingAuthenticationToken	The request was not signed.
	LambdaPermissionError	The caller is not authorized to invoke the Lambda function. The caller must have permission to invoke the Lambda function. Check the policies attached to the caller and ensure that they've been allowed to use `lambda:Invoke` for the configured function. The error message might contain details about an eventual error returned by the Lambda service when invoking the function (for example, status code, error code, error message and request ID).

HTTP status code	Error code	Description of error code	
404 Not Found	LambdaNotFound	The AWS Lambda function was not found. The configured Lambda function, version, or alias was not found when attempting to invoke it. Ensure that the S3 Object Lambda Access Point configuration points to the correct Lambda function ARN. The error message might contain details about an eventual error returned by the AWS Lambda service when invoking the function (for example, status code, error code, error message and request ID).	
	NoSuchAsyncRequest	The specified request was not found.	
	NoSuchObjectLockConfiguration	The specified object does not have an ObjectLock configuration.	

HTTP status code	Error code	Description of error code
	NoSuchUpload	The specified multipart upload does not exist. The upload ID might not be valid, or the multipart upload might have been aborted or completed.
	NoSuchWebsiteConfiguration	The specified bucket does not have a website configuration.
	NoTransformationDefined	No transformation found for this Object Lambda Access Point.
	ObjectLockConfigurationNotFoundError	The Object Lock configuration does not exist for this bucket.
405 Method Not Allowed	MethodNotAllowed	The specified method is not allowed against this resource.
409 Conflict	BucketAlreadyExists	The requested bucket name is not available. The bucket namespace is shared by all users of the system. Specify a different name and try again.

HTTP status code	Error code	Description of error code
	InvalidBucketState	The request is not valid for the current state of the bucket.
	OperationAborted	A conflicting conditional operation is currently in progress against this resource. Try again.
411 Length Required	MissingContentLength	You must provide the Content-Length HTTP header.
412 Precondition Failed	RequestIsNotMultiPartContent	A bucket POST request must be of the enclosure-type multipart/form-data.
416 Requested Range Not Satisfiable	InvalidRange	The requested range is not valid for the request. Try another range.

Understanding and managing Amazon S3 storage classes

Each object in Amazon S3 has a storage class associated with it. By default, objects in S3 are stored in the S3 Standard storage class, however Amazon S3 offers a range of other storage classes for the objects that you store. You choose a class depending on your use case scenario and performance access requirements. Choosing a storage class designed for your use case lets you optimize storage costs, performance, and availability for your objects. All of these storage classes offer high durability.

The following sections provide details of the various storage classes and how to set the storage class for your objects.

Topics

- Storage classes for frequently accessed objects
- Storage class for automatically optimizing data with changing or unknown access patterns
- Storage classes for infrequently accessed objects
- Storage classes for rarely accessed objects
- Storage class for Amazon S3 on Outposts
- Comparing the Amazon S3 storage classes
- Setting the storage class of an object
- Amazon S3 analytics – Storage Class Analysis
- Managing storage costs with Amazon S3 Intelligent-Tiering
- Understanding S3 Glacier storage classes for long-term data storage
- Working with archived objects

Storage classes for frequently accessed objects

For performance-sensitive use cases (those that require millisecond access time) and frequently accessed data, Amazon S3 provides the following storage classes:

- **S3 Standard** (`STANDARD`) – The default storage class. If you don't specify the storage class when you upload an object, Amazon S3 assigns the S3 Standard storage class. To help you optimize costs between S3 Standard and S3 Standard-IA you can use Amazon S3 analytics – Storage Class Analysis.
- **S3 Express One Zone** (`EXPRESS_ONEZONE`) – Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud object storage class available today, with data access speed up to 10x faster and with request costs 50 percent lower than S3 Standard. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. For more information, see S3 Express One Zone.

- **Reduced Redundancy Storage** (REDUCED_REDUNDANCY) – The Reduced Redundancy Storage (RRS) class is designed for noncritical, reproducible data that can be stored with less redundancy than the S3 Standard storage class.

  > **Important**
  >
  > We recommend not using this storage class. The S3 Standard storage class is more cost-effective.

  For durability, RRS objects have an average annual expected loss of 0.01 percent of objects. If an RRS object is lost, when requests are made to that object, Amazon S3 returns a 405 error.

Storage class for automatically optimizing data with changing or unknown access patterns

S3 Intelligent-Tiering (INTELLIGENT_TIERING) is an Amazon S3 storage class that's designed to optimize storage costs by automatically moving data to the most cost-effective access tier, without performance impact or operational overhead. S3 Intelligent-Tiering is the only cloud storage class that delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. S3 Intelligent-Tiering is the ideal storage class when you want to optimize storage costs for data that has unknown or changing access patterns. There are no retrieval fees for S3 Intelligent-Tiering.

For a small monthly object monitoring and automation fee, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers. S3 Intelligent-Tiering delivers automatic storage cost savings in three low-latency and high-throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is designed for 99.9% availability and 99.999999999% durability.

S3 Intelligent-Tiering automatically stores objects in three access tiers:

- **Frequent Access** – Objects that are uploaded or transitioned to S3 Intelligent-Tiering are automatically stored in the Frequent Access tier.
- **Infrequent Access** – S3 Intelligent-Tiering moves objects that have not been accessed in 30 consecutive days to the Infrequent Access tier.

- **Archive Instant Access** – With S3 Intelligent-Tiering, any existing objects that have not been accessed for 90 consecutive days are automatically moved to the Archive Instant Access tier.

In addition to these three tiers, S3 Intelligent-Tiering offers two optional archive access tiers:

- **Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days.
- **Deep Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier automatically archives objects that have not been accessed for a minimum of 180 consecutive days.

Note

- Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower-cost storage with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.
- Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, first restore the object by using `RestoreObject`.

You can move newly created data to S3 Intelligent-Tiering, setting it as your default storage class. You can also choose to activate one or both of the archive access tiers by using the `PutBucketIntelligentTieringConfiguration` API operation, the AWS CLI, or the Amazon S3 console. For more information about using S3 Intelligent-Tiering and activating the archive access tiers, see Using S3 Intelligent-Tiering.

To access objects in the Archive Access or Deep Archive Access tiers, you first need to restore them. For more information, see Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers.

Note

If the size of an object is less than 128 KB, it is not monitored and not eligible for auto-tiering. Smaller objects are always stored in the Frequent Access tier. For more information about S3 Intelligent-Tiering, see S3 Intelligent-Tiering access tiers.

Storage classes for infrequently accessed objects

The **S3 Standard-IA** and **S3 One Zone-IA** storage classes are designed for long-lived and infrequently accessed data. (IA stands for *infrequent access*.) S3 Standard-IA and S3 One Zone-IA objects are available for millisecond access (similar to the S3 Standard storage class). Amazon S3 charges a retrieval fee for these objects, so they are most suitable for infrequently accessed data. For pricing information, see Amazon S3 pricing.

For example, you might choose the S3 Standard-IA and S3 One Zone-IA storage classes to do the following:

- For storing backups.
- For older data that is accessed infrequently, but that still requires millisecond access. For example, when you upload data, you might choose the S3 Standard storage class, and use lifecycle configuration to tell Amazon S3 to transition the objects to the S3 Standard-IA or S3 One Zone-IA class.

  For more information about lifecycle management, see Managing the lifecycle of objects.

Note

The S3 Standard-IA and S3 One Zone-IA storage classes are suitable for objects larger than 128 KB that you plan to store for at least 30 days. If an object is less than 128 KB, Amazon S3 charges you for 128 KB. If you delete an object before the end of the 30-day minimum storage duration period, you are charged for 30 days. Objects that are deleted, overwritten, or transitioned to a different storage class before 30 days will incur the normal storage usage charge plus a pro-rated charge for the remainder of the 30-day minimum. For pricing information, see Amazon S3 pricing.

These storage classes differ as follows:

- **S3 Standard-IA** (`STANDARD_IA`) – Amazon S3 stores the object data redundantly across multiple geographically separated Availability Zones (similar to the S3 Standard storage class). S3 Standard-IA objects are resilient to the loss of an Availability Zone. This storage class offers greater availability and resiliency than the S3 One Zone-IA class. To help you optimize costs between S3 Standard and S3 Standard-IA you can use Amazon S3 analytics – Storage Class Analysis
- **S3 One Zone-IA** (`ONEZONE_IA`) – Amazon S3 stores the object data in only one Availability Zone, which makes it less expensive than S3 Standard-IA. However, the data is not resilient to the physical loss of the Availability Zone resulting from disasters, such as earthquakes and floods. The S3 One Zone-IA storage class is as durable as S3 Standard-IA, but it is less available and less resilient. For a comparison of storage class durability and availability, see Comparing the Amazon S3 storage classes at the end of this section. For pricing information, see Amazon S3 pricing. For data residency and isolation use cases, you can create directory buckets in AWS Local Zones and use the S3 Express One Zone (`EXPRESS_ONEZONE`) and S3 One Zone-IA (`ONEZONE_IA`) storage classes. For more information about directory buckets in Local Zones, see Data residency workloads.

We recommend the following:

- **S3 Standard-IA** (`STANDARD_IA`) – Use for your primary or only copy of data that can't be re-created.
- **S3 One Zone-IA** (`ONEZONE_IA`) – Use if you can re-create the data if the Availability Zone fails, for object replicas when configuring S3 Cross-Region Replication (CRR). Also, for data residency and isolation, you can create directory buckets in AWS Local Zones and use the S3 One Zone-IA storage class.

Storage classes for rarely accessed objects

The **S3 Glacier Instant Retrieval** (`GLACIER_IR`), **S3 Glacier Flexible Retrieval** (`GLACIER`), and **S3 Glacier Deep Archive** (`DEEP_ARCHIVE`) storage classes are designed for low-cost, long-term data storage and data archiving. These storage classes require minimum storage durations and retrieval fees making them most effective for rarely accessed data. For more information about S3 Glacier storage classes, see Understanding S3 Glacier storage classes for long-term data storage.

Amazon S3 provides the following S3 Glacier storage classes:

- **S3 Glacier Instant Retrieval** (GLACIER_IR) – Use for long-term data that's rarely accessed and requires milliseconds retrieval. Data in this storage class is available for real-time access.
- **S3 Glacier Flexible Retrieval** (GLACIER) – Use for archives where portions of the data might need to be retrieved in minutes. Data in this storage class is archived, and not available for real-time access.
- **S3 Glacier Deep Archive** (DEEP_ARCHIVE) – Use for archiving data that rarely needs to be accessed. Data in this storage class is archived, and not available for real-time access.

Retrieving archived objects

You can set the storage class of an object to S3 Glacier Flexible Retrieval (GLACIER) or S3 Glacier Deep Archive (DEEP_ARCHIVE) in the same ways that you do for the other storage classes as described in the section Setting the storage class of an object. However, S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects are archived, and not available for real-time access. For more information, see Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive.

> **Note**
>
> When you use S3 Glacier storage classes, your objects remain in Amazon S3. You can't access them directly through the separate Amazon Glacier service. For information about the Amazon Glacier service, see the Amazon Glacier Developer Guide.

Storage class for Amazon S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use the same API operations and features on AWS Outposts as you do on Amazon S3, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API.

S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS). The S3 Outposts storage class is available only for objects stored in buckets on Outposts. If you try to use this storage class with an S3 bucket in an AWS Region, an `InvalidStorageClass` error occurs. In addition, if you try to use other S3 storage classes with objects stored in S3 on Outposts buckets, the same error occurs.

Objects stored in the S3 Outposts (0UTP0STS) storage class are always encrypted by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3).

You can also explicitly choose to encrypt objects stored in the S3 Outposts storage class by using server-side encryption with customer-provided encryption keys (SSE-C). For more information, see Using server-side encryption with customer-provided keys (SSE-C).

> **Note**
>
> S3 on Outposts doesn't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

For more information about S3 on Outposts, see What is S3 on Outposts in the *Amazon S3 on Outposts User Guide*.

Comparing the Amazon S3 storage classes

The following table compares the storage classes, including their availability, durability, minimum storage duration, and other considerations.

Storage Class	Designed for	Durability (designed for)	Availability (designed for)	Availability Zones	Min storage duration	Min billable object size	Other Considerations
STANDARD	Frequently accessed data	99.999999999%	99.99%	>= 3	None	None	None
STANDARD_IA	Long-lived, infrequently accessed data	99.999999999%	99.9%	>= 3	30 days	128 KB	Per GB retrieval fees apply.
INTELLIGENT_TIERING	Long-lived data with changing or unknown access patterns	99.999999999%	99.9%	>= 3	30 days	None	Monitoring and automation fees per object apply. No retrieval fees.
ONEZONE_IA	Long-lived, infrequently accessed, non-critical data	99.999999999%	99.5%	1	30 days	128 KB	Per GB retrieval fees apply. Not resilient to the loss of the Availability Zone.
GLACIER	Long-term data archiving with retrieval times ranging from minutes to hours	99.999999999%	99.99% (after you restore objects)	>= 3	90 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects.
DEEP_ARCHIVE	Archiving rarely accessed data with a default retrieval time of 12 hours	99.999999999%	99.99% (after you restore objects)	>= 3	180 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects.
RRS (Not recommended)	Frequently accessed, non-critical data	99.99%	99.99%	>= 3	None	None	None

* S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Flexible Retrieval rate (required to identify

and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to S3 Glacier Flexible Retrieval. For more information about storage classes, see Amazon S3 storage classes.

** S3 Glacier Deep Archive requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Deep Archive rate (required to identify and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to Amazon S3 Glacier Deep Archive. For more information about storage classes, see Amazon S3 storage classes.

Be aware that all of the storage classes except for S3 One Zone-IA (`ONEZONE_IA`) and S3 Express One Zone (`EXPRESS_ONEZONE`) are designed to be resilient to the physical loss of an Availability Zone resulting from disasters. Also, consider costs, in addition to the performance requirements of your application scenario. For storage class pricing, see Amazon S3 pricing.

Setting the storage class of an object

You can specify a storage class for an object when you upload it. If you don't, Amazon S3 uses the default Amazon S3 Standard storage class for objects in general purpose buckets. You can also change the storage class of an object that's already stored in an Amazon S3 general purpose bucket to any other storage class using the Amazon S3 console, AWS SDKs, or the AWS Command Line Interface (AWS CLI). All of these approaches use Amazon S3 API operations to send requests to Amazon S3.

> **Note**
>
> You can't change the storage class of objects stored in directory buckets.

You can direct Amazon S3 to change the storage class of objects automatically by adding an S3 Lifecycle configuration to a bucket. For more information, see Managing the lifecycle of objects.

When setting up a S3 Replication configuration, you can set the storage class for replicated objects to any other storage class. However, you can't replicate objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see Replication configuration file elements.

When setting the storage class programmatically you provide the value of the storage class. The following is a list of console names for storage classes with their corresponding API values:

- **Reduced Redundancy Storage** – `REDUCED_REDUNDANCY`
- **S3 Express One Zone** – `EXPRESS_ONEZONE`
- **S3 Glacier Deep Archive** – `DEEP_ARCHIVE`
- **S3 Glacier Flexible Retrieval** – `GLACIER`
- **S3 Glacier Instant Retrieval** – `GLACIER_IR`
- **S3 Intelligent-Tiering** – `INTELLIGENT_TIERING`
- **S3 One Zone-IA** – `ONEZONE_IA`
- **S3 Standard** – `STANDARD`
- **S3 Standard-IA** – `STANDARD_IA`

Setting the storage class on a new object

To set the storage class when you upload an object, you can use the following methods.

Using the S3 console

To set the storage class when uploading a new object in the console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at: https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to upload your folders or files to.
4. Choose **Upload**.
5. In the **Upload** window, choose **Properties**.
6. Under Storage class, choose a storage classes for the files you're uploading.
7. (Optional) Configure any additional properties for the files you're uploading, For more information, see Uploading objects
8. In the Upload window, do one of the following:
    - Drag files and folders to the Upload window.

- Choose **Add file** or **Add folder**, choose the files or folders to upload, and choose **Open**.

9. Choose **Upload**.

Using the REST API

You can specify the storage class on an object when you create it using the `PutObject`, `POST Object` Object, and `CreateMultipartUpload` API operations, add the `x-amz-storage-class` request header. If you don't add this header, Amazon S3 uses the default S3 Standard (`STANDARD`) storage class.

This example request uses the `PutObject` command to set the storage class on a new object to S3 Intelligent-Tiering:

```
PUT /my-image.jpg HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.Region.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Using the AWS CLI

This example uses the `put-object` command to upload the *my_images.tar.bz2* to *amzn-s3-demo-bucket1* in the *GLACIER* storage class:

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key dir-1/my_images.tar.bz2 --
storage-class GLACIER --body my_images.tar.bz2
```

If the object size is more than 5 GB, use the following command to set the storage class:

```
aws s3 cp large_test_file s3://amzn-s3-demo-bucket1 --storage-class GLACIER
```

Changing the storage class for an existing object

To set the storage class when you upload an object, you can use the following methods.

Using the S3 console

You can change an object's storage class using the Amazon S3 console if the object size is less than 5 GB. If larger, we recommend adding an S3 Lifecycle configuration to change the object's storage class.

To change the storage class of an object in the console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket containing the objects you want to change.
4. Select the check box to the left of the names of the objects you want to change.
5. On the **Actions** menu, choose **Edit storage class** from the list of options that appears.
6. Select from the storage classes available for your object.
7. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
8. Choose **Save changes**. Amazon S3 saves your changes.

Using the REST API

To change the storage class of an existing object, use the following methods.

To change the storage class of an existing object, you make a copy of the object to the same location with a new storage class using the `CopyObject` operation. The following example request copies an object to itself with the storage class changed to S3 Intelligent-Tiering:

```
PUT /my-image.jpg HTTP/1.1
```

```
Host: amzn-s3-demo-bucket1.s3.Region.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: authorization string
x-amz-copy-source: /amzn-s3-demo-bucket1/my-image.jpg
x-amz-metadata-directive: COPY
x-amz-storage-class: INTELLIGENT_TIERING
```

Using the AWS CLI

This example uses the cp command to change the storage class of the of an existing object from its current storage class to *DEEP_ARCHIVE* storage class:

```
aws s3 cp object_S3_URI object_S3_URI --storage-class DEEP_ARCHIVE
```

Restricting access policy permissions to a specific storage class

When you grant access policy permissions for Amazon S3 operations, you can use the `s3:x-amz-storage-class` condition key to restrict which storage class to use when storing uploaded objects. For example, when you grant the `s3:PutObject` permission, you can restrict object uploads to a specific storage class. For an example policy, see Example: Restricting object uploads to objects with a specific storage class.

For more information about using conditions in policies and a complete list of Amazon S3 condition keys, see the following topics:

- Actions, resources, and condition keys for Amazon S3 in the *Service Authorization Reference*

  For more information about the permissions to S3 API operations by S3 resource types, see Required permissions for Amazon S3 API operations.
- Bucket policy examples using condition keys

Amazon S3 analytics – Storage Class Analysis

By using Amazon S3 analytics *Storage Class Analysis* you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. This new Amazon S3 analytics feature observes data access patterns to help you determine when to transition less

frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about storage classes, see Understanding and managing Amazon S3 storage classes.

After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. You can configure storage class analysis to analyze all the objects in a bucket. Or, you can configure filters to group objects together for analysis by common prefix (that is, objects that have names that begin with a common string), by object tags, or by both prefix and tags. You'll most likely find that filtering by object groups is the best way to benefit from storage class analysis.

> **Important**
>
> Storage class analysis only provides recommendations for Standard to Standard IA classes.

You can have multiple storage class analysis filters per bucket, up to 1,000, and will receive a separate analysis for each filter. Multiple filter configurations allow you analyze specific groups of objects to improve your lifecycle configurations that transition objects to STANDARD_IA.

Storage class analysis provides storage usage visualizations in the Amazon S3 console that are updated daily. You can also export this daily usage data to an S3 bucket and view them in a spreadsheet application, or with business intelligence tools, like Quick.

There are costs associated with the storage class analysis. For pricing information, see *Management and insights* Amazon S3 pricing.

Topics

- How do I set up storage class analysis?
- How do I use storage class analysis?
- How can I export storage class analysis data?
- Configuring storage class analysis

How do I set up storage class analysis?

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

  You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

  You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

  When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

- For information about how to configure storage class analysis in the Amazon S3 console, see Configuring storage class analysis.
- To use the Amazon S3 API, use the PutBucketAnalyticsConfiguration REST API, or the equivalent, from the AWS CLI or AWS SDKs.

How do I use storage class analysis?

You use storage class analysis to observe your data access patterns over time to gather information to help you improve the lifecycle management of your STANDARD_IA storage. After you configure a filter, you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. However, storage class analysis observes the access patterns of a filtered data set for 30 days or longer to gather information for analysis before giving a result. The analysis continues to run after the initial result and updates the result as the access patterns change

When you first configure a filter, the Amazon S3 console may take a moment to analyze your data.

Storage class analysis observes the access patterns of a filtered object data set for 30 days or longer to gather enough information for the analysis. After storage class analysis has gathered sufficient information, you'll see a message in the Amazon S3 console that analysis is complete.

When performing the analysis for infrequently accessed objects storage class analysis looks at the filtered set of objects grouped together based on age since they were uploaded to Amazon S3. Storage class analysis determines if the age group is infrequently accessed by looking at the following factors for the filtered data set:

- Objects in the STANDARD storage class that are larger than 128 KB.
- How much average total storage you have per age group.
- Average number of bytes transferred out (not frequency) per age group.
- Analytics export data only includes requests with data relevant to storage class analysis. This might cause differences in the number of requests, and the total upload and request bytes compared to what are shown in storage metrics or tracked by your own internal systems.
- Failed GET and PUT requests are not counted for the analysis. However, you will see failed requests in storage metrics.

How Much of My Storage did I Retrieve?

The Amazon S3 console graphs how much of the storage in the filtered data set has been retrieved for the observation period.

What Percentage of My Storage did I Retrieve?

The Amazon S3 console also graphs what percentage of the storage in the filtered data set has been retrieved for the observation period.

As stated earlier in this topic, when you are performing the analysis for infrequently accessed objects, storage class analysis looks at the filtered set of objects grouped together based on the age since they were uploaded to Amazon S3. The storage class analysis uses the following predefined object age groups:

- Amazon S3 Objects less than 15 days old
- Amazon S3 Objects 15-29 days old
- Amazon S3 Objects 30-44 days old
- Amazon S3 Objects 45-59 days old
- Amazon S3 Objects 60-74 days old
- Amazon S3 Objects 75-89 days old
- Amazon S3 Objects 90-119 days old

- Amazon S3 Objects 120-149 days old
- Amazon S3 Objects 150-179 days old
- Amazon S3 Objects 180-364 days old
- Amazon S3 Objects 365-729 days old
- Amazon S3 Objects 730 days and older

Usually it takes about 30 days of observing access patterns to gather enough information for an analysis result. It might take longer than 30 days, depending on the unique access pattern of your data. However, after you configure a filter you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. You can see analysis on a daily basis of object access broken down by object age group in the Amazon S3 console.

How Much of My Storage is Infrequently Accessed?

The Amazon S3 console shows the access patterns grouped by the predefined object age groups. The **Frequently accessed** or **Infrequently accessed** text shown is meant as a visual aid to help you in the lifecycle creation process.

How can I export storage class analysis data?

You can choose to have storage class analysis export analysis reports to a comma-separated values (CSV) flat file. Reports are updated daily and are based on the object age group filters you configure. When using the Amazon S3 console you can choose the export report option when you create a filter. When selecting data export you specify a destination bucket and optional destination prefix where the file is written. You can export the data to a destination bucket in a different account. The destination bucket must be in the same region as the bucket that you configure to be analyzed.

You must create a bucket policy on the destination bucket to grant permissions to Amazon S3 to verify what AWS account owns the bucket and to write objects to the bucket in the defined location. For an example policy, see Grant permissions for S3 Inventory and S3 analytics.

After you configure storage class analysis reports, you start getting the exported report daily after 24 hours. After that, Amazon S3 continues monitoring and providing daily exports.

You can open the CSV file in a spreadsheet application or import the file into other applications like AWS Quick. For information on using Amazon S3 objects with AWS Quick, see the AWS Quick User Guide.

Data in the exported file is sorted by date within object age group as shown in following examples. If the storage class is STANDARD the row also contains data for the columns `ObjectAgeForSIATransition` and `RecommendedObjectAgeForSIATransition`.

Date	ConfigId	Filter	StorageClass	ObjectAge	ObjectCount	DataUploaded_MB	Storage_MB	DataRetrieved_MB	GetRequestCount	CumulativeAccessRatio	ObjectAgeForSIATransition	RecommendedObjectAgeForSIATransition
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/2/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/5/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		

At the end of the report the object age group is given as ALL. The ALL rows contain cumulative totals, including objects smaller than 128 KB, for all the age groups for that day.

8/24/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0	000-014
9/3/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0.02426125	015-029
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0.03545875	015-029
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0	000-014
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0	000-014
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0.0209529	015-029
9/4/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0.02304819	015-029
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0	000-014
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0	000-014
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0.03073092	015-029
8/20/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3		0.4599			0	000-014

The next section describes the columns used in the report.

Exported file layout

The following table describes the Amazon S3 storage class analysis export file layout.

Configuring storage class analysis

By using the Amazon S3 analytics storage class analysis tool, you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. Storage class analysis observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about STANDARD_IA, see the Amazon S3 FAQ and Understanding and managing Amazon S3 storage classes.

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

  You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

  When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

> **Important**
>
> Storage class analysis does not give recommendations for transitions to the ONEZONE_IA or S3 Glacier Flexible Retrieval storage classes.
> If you want to configure storage class analysis to export your findings as a .csv file and the destination bucket uses default bucket encryption with a AWS KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see Granting Amazon S3 permission to use your customer managed key for encryption.

For more information about analytics, see Amazon S3 analytics – Storage Class Analysis.

Using the S3 console

To configure storage class analysis

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the buckets list, choose the name of the bucket for which you want to configure storage class analysis.
4. Choose the **Metrics** tab.

5. Under **Storage Class Analysis**, choose **Create analytics configuration**.
6. Type a name for the filter. If you want to analyze the whole bucket, leave the **Prefix** field empty.
7. In the **Prefix** field, type text for the prefix for the objects that you want to analyze.
8. To add a tag, choose **Add tag**. Enter a key and value for the tag. You can enter one prefix and multiple tags.
9. Optionally, you can choose **Enable** under **Export CSV** to export analysis reports to a comma-separated values (.csv) flat file. Choose a destination bucket where the file can be stored. You can type a prefix for the destination bucket. The destination bucket must be in the same AWS Region as the bucket for which you are setting up the analysis. The destination bucket can be in a different AWS account.

   If the destination bucket for the .csv file uses default bucket encryption with a KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see Granting Amazon S3 permission to use your customer managed key for encryption.
10. Choose **Create Configuration**.

Amazon S3 creates a bucket policy on the destination bucket that grants Amazon S3 write permission. This will allow it to write the export data to the bucket.

If an error occurs when you try to create the bucket policy, you'll be given instructions on how to fix it. For example, if you chose a destination bucket in another AWS account and do not have permissions to read and write to the bucket policy, you'll see the following message. You must have the destination bucket owner add the displayed bucket policy to the destination bucket. If the policy is not added to the destination bucket you won't get the export data because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, then the correct account ID of the source bucket must be substituted in the policy.

For information about the exported data and how the filter works, see Amazon S3 analytics – Storage Class Analysis.

Using the REST API

To configure Storage Class Analysis using the REST API, use the PutBucketAnalyticsConfiguration. You can also use the equivalent operation with the AWS CLI or AWS SDKs.

You can use the following REST APIs to work with Storage Class Analysis:

- DELETE Bucket Analytics configuration
- GET Bucket Analytics configuration
- List Bucket Analytics Configuration

Managing storage costs with Amazon S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class is designed to optimize storage costs by automatically moving data to the most cost-effective access tier when access patterns change, without operational overhead or impact on performance. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

S3 Intelligent-Tiering delivers automatic storage cost savings in three low latency and high throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. There are no retrieval charges in S3 Intelligent-Tiering. If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier. No additional tiering charges apply when objects are moved between access tiers within the S3 Intelligent-Tiering storage class.

S3 Intelligent-Tiering is the recommended storage class for data with unknown, changing, or unpredictable access patterns, independent of object size or retention period, such as data lakes, data analytics, and new applications.

The S3 Intelligent-Tiering storage class supports all Amazon S3 features, including the following:

- S3 Inventory, for verifying the access tier of objects
- S3 Replication, for replicating data to any AWS Region
- S3 Storage Lens, for viewing storage usage and activity metrics
- Server-side encryption, for protecting object data
- S3 Object Lock, for preventing accidental deletion of data
- AWS PrivateLink, for accessing Amazon S3 through a private endpoint in a virtual private cloud (VPC)

For information about using S3 Intelligent-Tiering, see the following sections:

Topics

- How S3 Intelligent-Tiering works
- Using S3 Intelligent-Tiering
- Managing S3 Intelligent-Tiering

How S3 Intelligent-Tiering works

The Amazon S3 Intelligent-Tiering storage class automatically stores objects in three access tiers. One tier is optimized for frequent access, one lower-cost tier is optimized for infrequent access, and another very low-cost tier is optimized for rarely accessed data. For a low monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects to the Infrequent Access tier when they haven't been accessed for 30 consecutive days. After 90 days of no access, the objects are moved to the Archive Instant Access tier without performance impact or operational overhead.

To get the lowest storage cost for data that can be accessed in minutes to hours, activate archiving capabilities to add two additional access tiers. You can tier down objects to the Archive Access tier, the Deep Archive Access tier, or both. With Archive Access, S3 Intelligent-Tiering moves objects that have not been accessed for a minimum of 90 consecutive days to the Archive Access tier. With Deep Archive Access, S3 Intelligent-Tiering moves objects to the Deep Archive Access tier after a minimum of 180 consecutive days of no access. For both tiers, you can configure the number of days of no access based on your needs.

The following actions constitute access that prevents tiering your objects down to the Archive Access tier or the Deep Archive Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking CopyObject, UploadPartCopy, or replicating objects with S3 Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking GetObject, PutObject, RestoreObject, CompleteMultipartUpload, or SelectObjectContent.

For example, if your objects are accessed through `SelectObjectContent` before your specified number of days of no access (for example, 180 days), that action resets the timer. Your objects won't move to the Archive Access tier or the Deep Archive Access tier until the time after the last `SelectObjectContent` request reaches your specified number of days.

If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier.

The following actions constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking CopyObject, UploadPartCopy, or replicating objects with Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking GetObject, PutObject, RestoreObject, or CompleteMultipartUpload.

Other actions **don't** constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier. The following is a sample, not a definitive list, of such actions:

- Invoking HeadObject, GetObjectTagging, PutObjectTagging, ListObjects, ListObjectsV2, ListObjectVersions, and UpdateObjectEncryption.
- Invoking SelectObjectContent doesn't constitute access that tiers objects up to a Frequent Access tier. In addition, it doesn't prevent tiering objects down from the Frequent Access tier to the Infrequent Access tier, and then to the Archive Instant Access tier.

You can use S3 Intelligent-Tiering as your default storage class for newly created data by specifying `INTELLIGENT-TIERING` in the x-amz-storage-class request header when calling the `PutObject`, `CopyObject`, or `CreateMultipartUpload` operations. S3 Intelligent-Tiering is designed for 99.9% availability and 99.999999999% durability.

> **Note**
>
> If the size of an object is less than 128 KB, it is not monitored and is not eligible for automatic tiering. Smaller objects are always stored in the Frequent Access tier.

S3 Intelligent-Tiering access tiers

The following section explains the different automatic and optional access tiers. When objects move between access tiers, the storage class remains the same (S3 Intelligent-Tiering).

Frequent Access tier (automatic)

This is the default access tier that any object created or transitioned to S3 Intelligent-Tiering begins its lifecycle in. An object remains in this tier as long as it is being accessed. The Frequent Access tier provides low latency and high-throughput performance.

Infrequent Access tier (automatic)

If an object is not accessed for 30 consecutive days, the object moves to the Infrequent Access tier. The Infrequent Access tier provides low latency and high-throughput performance.

Archive Instant Access tier (automatic)

If an object is not accessed for 90 consecutive days, the object moves to the Archive Instant Access tier. The Archive Instant Access tier provides low latency and high-throughput performance.

Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Archive Access tier has the same performance as the S3 Glacier Flexible Retrieval storage class.

Standard retrieval times for this access tier can range from 3–5 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within minutes. For more information about retrieval options and times, see the section called “Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”.

> **Note**
>
> Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower storage costs, with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.

Deep Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier

automatically archives objects that have not been accessed for a minimum of 180 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Deep Archive Access tier has the same performance as the S3 Glacier Deep Archive storage class.

Standard retrieval of objects in this access tier occurs within 12 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within 9 hours. For more information about retrieval options and times, see the section called "Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers".

Note

Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, you must first restore the object by using the `RestoreObject` operation.
You can restore archived objects with up to 1,000 transactions per second (TPS) of object restore requests per account per AWS Region from S3 Intelligent-Tiering Archive Access, and S3 Intelligent-Tiering Deep Archive Access.

Using S3 Intelligent-Tiering

You can use the S3 Intelligent-Tiering storage class to automatically optimize storage costs. S3 Intelligent-Tiering delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. For data that can be accessed asynchronously, you can choose to enable automatic archiving within the S3 Intelligent-Tiering storage class using the AWS Management Console, AWS CLI, or Amazon S3 API.

Moving data to S3 Intelligent-Tiering

There are two ways to move data into S3 Intelligent-Tiering. You can upload objects directly into S3 Intelligent-Tiering from the console or programmatically using a PUT operation. For more information, see Setting the storage class of an object. You can also configure S3 Lifecycle configurations to transition objects from S3 Standard or S3 Standard-Infrequent Access to S3 Intelligent-Tiering.

Uploading data to S3 Intelligent-Tiering using Direct PUT

When you upload an object to the S3 Intelligent-Tiering storage class using the PUT API operation, you specify S3 Intelligent-Tiering in the `x-amz-storage-class` request header.

The following request stores the image, `my-image.jpg`, in the `myBucket` bucket. The request uses the `x-amz-storage-class` header to request that the object is stored using the S3 Intelligent-Tiering storage class.

Example

```
PUT /my-image.jpg HTTP/1.1
Host: myBucket.s3.<Region>.amazonaws.com (http://amazonaws.com/)
Date: Wed, 1 Sep 2021 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Transitioning data to S3 Intelligent-Tiering from S3 Standard or S3 Standard-Infrequent Access using S3 Lifecycle

You can add rules to an S3 Lifecycle configuration to tell Amazon S3 to transition objects from one storage class to another. For information on supported transitions and related constraints, see Transitioning objects using S3 Lifecycle.

You can specify S3 Lifecycle configurations at the bucket or prefix level. In this S3 Lifecycle configuration rule, the filter specifies a key prefix (`documents/`). Therefore, the rule applies to objects with key name prefix `documents/`, such as `documents/doc1.txt` and `documents/doc2.txt`. The rule specifies a `Transition` action directing Amazon S3 to transition objects to the S3 Intelligent-Tiering storage class 0 days after creation. In this case, objects are eligible for transition to S3 Intelligent-Tiering at midnight UTC following creation.

Example

```
<LifecycleConfiguration>
  <Rule>
    <ID>ExampleRule</ID>
    <Filter>
       <Prefix>documents/</Prefix>
```

```
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>INTELLIGENT_TIERING</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate Lifecycle rules for current and noncurrent object versions.

For more information, see Lifecycle configuration elements.

Enabling S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To get the lowest storage cost on data that can be accessed in minutes to hours, you can activate one or both of the archive access tiers by creating a bucket, prefix, or object tag level configuration using the AWS Management Console, AWS CLI, or Amazon S3 API.

Using the S3 console

To enable S3 Intelligent-Tiering automatic archiving

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. Choose **Properties**.
4. Navigate to the **S3 Intelligent-Tiering Archive configurations** section and choose **Create configuration**.
5. In the **Archive configuration settings** section, specify a descriptive configuration name for your S3 Intelligent-Tiering Archive configuration.
6. Under **Choose a configuration scope**, choose a configuration scope to use. Optionally, you can limit the configuration scope to specified objects within a bucket using a shared prefix, object tag, or combination of the two.

    a. To limit the scope of the configuration, select **Limit the scope of this configuration using one or more filters**.

    b. To limit the scope of the configuration using a single prefix, enter the prefix under **Prefix**.

c. To limit the scope of the configuration using object tags, select **Add tag** and enter a value for Key.

7. Under **Status**, select **Enable**.
8. In the **Archive settings** section, select one or both of the Archive Access tiers to enable.
9. Choose **Create**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Intelligent-Tiering configurations:

- `delete-bucket-intelligent-tiering-configuration`
- `get-bucket-intelligent-tiering-configuration`
- `list-bucket-intelligent-tiering-configurations`
- `put-bucket-intelligent-tiering-configuration`

For instructions on setting up the AWS CLI, see Developing with Amazon S3 using the AWS CLI in the *Amazon S3 API Reference*.

When using the AWS CLI, you cannot specify the configuration as an XML file. You must specify the JSON instead. The following is an example XML S3 Intelligent-Tiering configuration and equivalent JSON that you can specify in an AWS CLI command.

The following example puts an S3 Intelligent-Tiering configuration to the specified bucket.

Example `put-bucket-intelligent-tiering-configuration`

JSON

```
{
  "Id": "string",
  "Filter": {
    "Prefix": "string",
    "Tag": {
      "Key": "string",
      "Value": "string"
    },
    "And": {
      "Prefix": "string",
```

```
      "Tags": [
        {
          "Key": "string",
          "Value": "string"
        }
        ...
      ]
    }
  },
  "Status": "Enabled"|"Disabled",
  "Tierings": [
    {
      "Days": integer,
      "AccessTier": "ARCHIVE_ACCESS"|"DEEP_ARCHIVE_ACCESS"
    }
    ...
  ]
}
```

XML

```
PUT /?intelligent-tiering&id=Id HTTP/1.1
Host: Bucket.s3.amazonaws.com
<?xml version="1.0" encoding="UTF-8"?>
<IntelligentTieringConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
   <Id>string</Id>
   <Filter>
      <And>
         <Prefix>string</Prefix>
         <Tag>
            <Key>string</Key>
            <Value>string</Value>
         </Tag>
         ...
      </And>
      <Prefix>string</Prefix>
      <Tag>
         <Key>string</Key>
         <Value>string</Value>
      </Tag>
   </Filter>
   <Status>string</Status>
   <Tiering>
```

```
      <AccessTier>string</AccessTier>
      <Days>integer</Days>
   </Tiering>
   ...
</IntelligentTieringConfiguration>
```

Using the PUT API operation

You can use the PutBucketIntelligentTieringConfiguration operation for a specified bucket and up to 1,000 S3 Intelligent-Tiering configurations per bucket. You can define which objects within a bucket are eligible for the archive access tiers using a shared prefix or object tag. Using a shared prefix or object tag allows you to align to specific business applications, workflows, or internal organizations. You also have the flexibility to activate the Archive Access tier, the Deep Archive Access tier, or both.

Managing S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class delivers automatic storage cost savings in three low-latency and high-throughput access tiers. It also offers optional archive capabilities to help you get the lowest storage costs in the cloud for data that can be accessed in minutes to hours.

Identifying which S3 Intelligent-Tiering access tier objects are stored in

To get a list of your objects and their corresponding metadata, including their S3 Intelligent-Tiering access tier, you can use Amazon S3 Inventory. S3 Inventory provides CSV, ORC, or Parquet output files that list your objects and their corresponding metadata. You can receive these inventory reports on either a daily or weekly basis for an Amazon S3 bucket or a shared prefix. (*Shared prefix* refers to objects that have names that begin with a common string.)

Viewing the archive status of an object within S3 Intelligent-Tiering

To receive notice when an object within the S3 Intelligent-Tiering storage class has moved to either the Archive Access tier or the Deep Archive Access tier, you can set up S3 Event Notifications. For more information, see Enabling event notifications.

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see Amazon S3 Event Notifications.

The following is an example of a message that Amazon S3 sends to publish an `s3:IntelligentTiering` event. For more information, see the section called “Event message structure”.

```
{
   "Records":[
      {
         "eventVersion":"2.3",
         "eventSource":"aws:s3",
         "awsRegion":"us-west-2",
         "eventTime":"1970-01-01T00:00:00.000Z",
         "eventName":"IntelligentTiering",
         "userIdentity":{
            "principalId":"s3.amazonaws.com"
         },
         "requestParameters":{
            "sourceIPAddress":"s3.amazonaws.com"
         },
         "responseElements":{
            "x-amz-request-id":"C3D13FE58DE4C810",
            "x-amz-id-2":"FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvANOjpD"
         },
         "s3":{
            "s3SchemaVersion":"1.0",
            "configurationId":"testConfigRule",
            "bucket":{
               "name":"amzn-s3-demo-bucket",
               "ownerIdentity":{
                  "principalId":"A3NL1KOZZKExample"
               },
               "arn":"arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "object":{
               "key":"HappyFace.jpg",
               "size":1024,
               "eTag":"d41d8cd98f00b204e9800998ecf8427e",
            }
         },
         "intelligentTieringEventData":{
            "destinationAccessTier": "ARCHIVE_ACCESS"
            }
      }
```

```
    ]
}
```

You can also use a HEAD object request to view an object's archive status. If an object is stored in the S3 Intelligent-Tiering storage class and is in one of the archive tiers, the HEAD object response shows the current archive tier. To show the archive tier, the request uses the x-amz-archive-status header.

The following HEAD object request returns the metadata of an object (in this case, *my-image.jpg*).

Example

```
HEAD /my-image.jpg HTTP/1.1
Host: bucket.s3.region.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:02236Q3V0RonhpaBX5sCYVf1bNRuU=
```

You can also use HEAD object requests to monitor the status of a `restore-object` request. If the archive restoration is in progress, the HEAD object response includes the x-amz-restore header.

The following sample HEAD object response shows an object archived by using S3 Intelligent-Tiering with a restore request in progress.

Example

```
HTTP/1.1 200 OK
x-amz-id-2: FSVaTMjrmBp3Izs1NnwBZeu7M19iI8UbxMbi0A8AirHANJBo+hEftBuiESACOMJp
x-amz-request-id: E5CEFCB143EB505A
Date: Fri, 13 Nov 2020 00:28:38 GMT
Last-Modified: Mon, 15 Oct 2012 21:58:07 GMT
ETag: "1accb31fcf202eba0c0f41fa2f09b4d7"
x-amz-storage-class: 'INTELLIGENT_TIERING'
x-amz-archive-status: 'ARCHIVE_ACCESS'
x-amz-restore: 'ongoing-request="true"'
x-amz-restore-request-date: 'Fri, 13 Nov 2020 00:20:00 GMT'
Accept-Ranges: bytes
Content-Type: binary/octet-stream
Content-Length: 300
Server: AmazonS3
```

Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a restore request, and then wait until the object is moved into the Frequent Access tier. For more information about archived objects, see the section called "Working with archived objects".

When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. Afterwards, if the object isn't accessed for 30 consecutive days, it automatically moves into the Infrequent Access tier. Then, after a minimum of 90 consecutive days of no access, the object moves into the Archive Access tier. After a minimum of 180 consecutive days of no access, the object moves into the Deep Archive Access tier. For more information, see the section called "How S3 Intelligent-Tiering works".

You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the Amazon S3 REST API, the AWS SDKs, or the AWS Command Line Interface (AWS CLI). For more information, see the section called "Working with archived objects".

Understanding S3 Glacier storage classes for long-term data storage

You can use Amazon S3 S3 Glacier storage classes to provide cost-effective solutions to storing long-term data that isn't accessed often. The S3 Glacier storage classes are:

- S3 Glacier Instant Retrieval
- S3 Glacier Flexible Retrieval
- S3 Glacier Deep Archive

You choose one of these storage classes based on how often you access your data and how fast you need to retrieve it. Each of these storage classes offer the same durability and resiliency as the S3 Standard storage class, but at lower storage costs. For more information about the S3 Glacier storage classes, see https://aws.amazon.com/s3/storage-classes/glacier/.

Topics

- Comparing the S3 Glacier storage classes
- S3 Glacier Instant Retrieval
- S3 Glacier Flexible Retrieval
- S3 Glacier Deep Archive

- Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive
- How these storage classes differ from the Amazon Glacier service

Comparing the S3 Glacier storage classes

Each S3 Glacier storage class has a minimum storage duration for all objects. If you delete, overwrite, or transition the object to a different storage class before the minimum, you are charged for the remainder of that duration.

Some S3 Glacier storage classes are archival, which means the objects stored in those classes are archived and not available for real-time access. For more information, see Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive.

Storage classes designed for less frequent access patterns with longer retrieval times offer lower storage costs. For pricing information, see https://aws.amazon.com/s3/pricing/.

The following table summarizes the key points to consider when choosing a S3 Glacier storage class:

S3 Glacier Instant Retrieval

We recommend using S3 Glacier Instant Retrieval for long-term data that's accessed once per quarter and requires millisecond retrieval times. This storage class is ideal for performance-sensitive use cases such as image hosting, file-sharing applications, and storing medical records for access during appointments.

S3 Glacier Instant Retrieval storage class offers real-time access to your objects with the same latency and throughput performance as the S3 Standard-IA storage class. When compared to S3 Standard-IA, S3 Glacier Instant Retrieval has lower storage costs but higher data access costs.

There is a minimum object size of 128 KB for data stored in the S3 Glacier Instant Retrieval storage class. This storage class also has a minimum storage duration period of 90 days.

S3 Glacier Flexible Retrieval

We recommend using S3 Glacier Flexible Retrieval for archive data that's accessed one to two times a year and doesn't require immediate access. S3 Glacier Flexible Retrieval offers flexible retrieval times to help you balance costs, with access times ranging from a few minutes to hours, and free bulk retrievals. This storage class is ideal for backup and disaster recovery.

Objects stored in S3 Glacier Flexible Retrieval are archived and not available for real-time access. For more information, see Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive. To access these objects, you first initiate a restore request which creates a temporary copy of the object that you can access when the request completes. For information, see Working with archived objects. When you restore an object, you can choose a retrieval tier to meet your use case, with lower costs for longer restore times.

The following retrieval tiers are available for S3 Glacier Flexible Retrieval:

- **Expedited retrieval** – Typically restores the object in 1–5 minutes. Expedited retrievals are subject to demand, so to make sure you have reliable and predictable restore times, we recommend that you purchase provisioned retrieval capacity. For more information, see Provisioned capacity.
- **Standard retrieval** – Typically restores the object in 3–5 hours, or within 1 minute to 5 hours when you use S3 Batch Operations. For more information, see Restore objects with Batch Operations.
- **Bulk retrieval** – Typically restores the object within 5–12 hours. Bulk retrievals are free.

For any retrieval option, objects larger than 5 TB typically finish within 48 hours with up to 300 megabytes per second (MBps) of retrieval throughput. For more information, see Understanding archive retrieval options.

The minimum storage duration for objects in S3 Glacier Flexible Retrieval storage class is 90 days.

S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each object. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for S3 Glacier Flexible Retrieval. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

S3 Glacier Deep Archive

We recommend using S3 Glacier Deep Archive for archive data that's accessed less than once a year. This storage class is designed for retaining data sets for multiple years to meet compliance requirements and can also be used for backup or disaster recovery or any infrequently accessed data that you can wait up to 72 hours to retrieve. S3 Glacier Deep Archive is the lowest-cost storage option in AWS.

Objects stored in S3 Glacier Deep Archive are archived and not available for real-time access. For more information, see Understanding archival storage in S3 Glacier Flexible Retrieval and S3

Glacier Deep Archive. To access these objects, you first initiate a restore request which creates a temporary copy of the object that you can access when the request completes. For information, see Working with archived objects. When you restore an object, you can choose a retrieval tier to meet your use case, with lower costs for longer restore times.

The following retrieval tiers are available for S3 Glacier Deep Archive:

- **Standard retrieval** – Typically restores the object within 12 hours, or within 9–12 hours when you use S3 Batch Operations. For more information, see Restore objects with Batch Operations.
- **Bulk retrieval** – Typically restores the object within 48 hours at a fraction of the cost of the Standard retrieval tier.

The minimum storage duration for objects in S3 Glacier Deep Archive storage class is 180 days.

S3 Glacier Deep Archive requires 40 KB of additional metadata for each object. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for S3 Glacier Deep Archive. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive

S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are archival storage classes. This means that when you store an object in these storage classes that object is archived, and cannot be accessed directly. To access an archived object, you submit a restore request for it, and then wait for the service to restore the object. The restore request restores a temporary copy of the object, and that copy is deleted when the duration you specified in the request expires. For more information, see Working with archived objects.

The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

> **Note**
>
> The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

You can restore archived objects in these storage classes with up to 1,000 transactions per second (TPS) of object restore requests per account per AWS Region.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – Each archived object requires 40 KB of additional metadata. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for that storage class. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

  If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.
- **Multipart upload pricing** – Objects in S3-storage-class-glacier; and S3 Glacier Deep Archive are billed at S3 Standard storage class rates when you upload them using multipart uploads. For more information, see Multipart upload and pricing.
- **Minimum 30 day storage charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep Archive. Deleting data that is archived to these storage classes doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges for the remainder of that duration.
- **Data retrieval charges** – When you restore an archived objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive there are per-request data retrieval charges. These charges vary based on the retrieval tier you choose when you initiate a restore. For pricing information, see Amazon S3 pricing.

- **S3 Lifecycle** – When you restore an archived objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive there are per-request data retrieval charges. These charges vary based on the retrieval tier you choose when you initiate a restore. For pricing information, see Amazon S3 pricing.

Restoring archived objects

Archived objects aren't accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A HeadObject or GetObject API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

> **Note**
>
> When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see Amazon S3 pricing.

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see Restoring an archived object.

How these storage classes differ from the Amazon Glacier service

The S3 Glacier storage classes are part of the Amazon S3 service and store data as objects in S3 buckets. You can manage objects in these storage classes using the S3 console or programmatically using the S3 APIs or SDKs. When you store objects in S3 Glacier storage classes, you can use S3 features such as advanced encryption, object tagging, and S3 Lifecycle configurations to help manage data accessibility and cost.

> **Important**
>
> We recommend using the S3 Glacier storage classes within the Amazon S3 service for all of your long-term data.

The Amazon Glacier service is a separate service that stores data as archives within vaults. This service doesn't support Amazon S3 features and doesn't provide console support for data upload and download operations. We don't recommend using the Amazon Glacier service for your long-term data. Data stored in this service isn't accessible from the Amazon S3 service. If you are looking for information on the Amazon Glacier service, see the Amazon Glacier Developer Guide. To transfer data from the Amazon Glacier service to a storage class in Amazon S3 see Data Transfer from Amazon Glacier Vaults to Amazon S3 in the AWS solutions library.

Working with archived objects

To reduce your storage costs for infrequently accessed objects, you can *archive* those objects. When you archive an object, it is moved into low-cost storage, which means that you can't access it in real time.

Although archived objects are not accessible in real time, you can restore them in minutes or hours, depending on the storage class. You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the REST API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI). For instructions, see Restoring an archived object.

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

> **Note**
>
> Objects stored in the S3 Glacier Instant Retrieval storage class are not archived. S3 Glacier Instant Retrieval provides real-time access with millisecond retrieval latency and does not require a restore operation. For more information about storage classes, see Understanding and managing Amazon S3 storage classes.

To restore archived objects, you must do the following:

- For objects in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, you must initiate the restore request and wait until a temporary copy of the object is available. When a temporary copy of the restored object is created, the object's storage class remains the same. (A HeadObject or GetObject API operation request returns S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)
- For objects in the S3 Intelligent-Tiering Archive Access and S3 Intelligent-Tiering Deep Archive Access tiers, you must initiate the restore request and wait until the object is moved into the Frequent Access tier.

For more information about how all Amazon S3 storage classes compare, see Understanding and managing Amazon S3 storage classes. For more information about S3 Intelligent-Tiering, see the section called "How S3 Intelligent-Tiering works".

The time it takes a restore job to finish depends on which archive storage class or storage tier you use and which retrieval option you specify: Expedited (only available for S3 Glacier Flexible Retrieval and S3 Intelligent-Tiering Archive Access), Standard, or Bulk. For more information, see Understanding archive retrieval options.

You can be notified when your restore is complete by using Amazon S3 Event Notifications. For more information, see Amazon S3 Event Notifications.

Restoring objects from Amazon Glacier

When you use S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 restores a temporary copy of the object only for the specified duration. After that, it deletes the restored object copy. You can modify the expiration period of a restored copy by reissuing a restore request. In this case, Amazon S3 updates the expiration period relative to the current time.

> **Note**
>
> When you restore an archived object from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, you pay for both the archived object and the copy that you restored temporarily. For information about pricing, see Amazon S3 pricing.

Amazon S3 calculates the expiration time of the restored object copy by adding the number of days specified in the restoration request to the time when the requested restoration is completed. Amazon S3 then rounds the resulting time to the next day at midnight Universal Coordinated Time

(UTC). For example, suppose that a restored object copy was created on October 15, 2012, at 10:30 AM UTC, and the restoration period was specified as 3 days. In this case, the restored copy expires on October 19, 2012, at 00:00 UTC, at which time Amazon S3 deletes the object copy.

Restoring objects from S3 Intelligent-Tiering

When you restore an object from the S3 Intelligent-Tiering Archive Access tier or S3 Intelligent-Tiering Deep Archive Access tier, the object moves back into the S3 Intelligent-Tiering Frequent Access tier. If the object is not accessed after 30 consecutive days, it automatically moves into the Infrequent Access tier. After a minimum of 90 consecutive days of no access, the object moves into the S3 Intelligent-Tiering Archive Access tier. If the object is not accessed after a minimum of 180 consecutive days, the object moves into the Deep Archive Access tier.

> **Note**
>
> Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the `Days` value.

Using S3 Batch Operations with restore requests

To restore more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

Topics

- Understanding archive retrieval options
- Restoring an archived object

Understanding archive retrieval options

Amazon S3 has three archival storage classes - S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive. While objects stored in the S3 Glacier Instant Retrieval storage class are immediately available using GET, to access data stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes you first need to retrieve data using the RestoreObject REST API. Restoring datasets made up of tens of millions of objects or hundreds of

terabytes of data could take longer than typical restore times and need special considerations. For more information, see Restoring large datasets.

You can choose from three retrieval access options to restore your archived objects based on your desired retrieval speed – Expedited, Standard and Bulk.

- **Expedited retrieval** – Quickly access your data stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. You can use this option for occasional urgent requests for up to hundreds of objects. Objects under 250 megabytes in size are typically made available within 1–5 minutes, and objects 250 megabytes or larger in size are typically retrieved with up to 300 megabytes per second of retrieval throughput. In addition, you have the option to purchase Provisioned Capacity for Expedited retrievals. Provisioned Capacity helps ensure that Expedited retrieval capacity is available when you need it. For more information, see Provisioned capacity.

  > **Note**
  >
  > Expedited retrievals are a premium feature and are charged at the Expedited request and retrieval rate. For information about Amazon S3 pricing, see Amazon S3 Pricing.

- **Standard retrieval** – Access your data within several hours. Standard is the default option for requests that do not specify the retrieval option. Standard retrievals typically finish within 3–5 hours for the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. Standard retrievals typically finish within 12 hours for the S3 Glacier Deep Archive storage class or S3 Intelligent-Tiering Deep Archive Access tier. Standard retrievals are free for objects stored in the S3 Intelligent-Tiering storage class.

  > **Note**
  >
  > - For objects stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier, Standard retrievals initiated by using the S3 Batch Operations restore operation typically start within minutes and finish within 3-5 hours at a throughput of up to 1–2 petabytes per day.
  > - For objects in the S3 Glacier Deep Archive storage class or the S3 Intelligent-Tiering Deep Archive Access tier, Standard retrievals initiated by using Batch Operations typically start to complete within 9 hours at a throughput of up to 1–2 petabytes per day.

- **Bulk retrieval** – Access your data by using the lowest-cost retrieval option in S3 Glacier storage classes. With Bulk retrievals, you can retrieve large amounts of data inexpensively. For objects stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier, Bulk retrievals typically finish within 5–12 hours. For objects stored in the S3 Glacier Deep Archive storage class or the S3 Intelligent-Tiering Deep Archive Access tier, these retrievals typically finish within 48 hours. Bulk retrievals are free for objects that are stored in the S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering storage classes.

The following table summarizes the archive retrieval options. For information about pricing, see Amazon S3 pricing.

To make an `Expedited`, `Standard`, or `Bulk` retrieval, set the `Tier` request element in the RestoreObject REST API operation request to the option that you want, or the equivalent in the AWS Command Line Interface (AWS CLI) or AWS SDKs. If you purchased provisioned capacity, all Expedited retrievals are automatically served through your provisioned capacity.

Restoring large datasets

Restoring datasets made up of tens of millions of objects or hundreds of terabytes of data could take longer than typical restore times for any retrieval tier due to retrieval limits.

When you initiate restore requests for objects that are stored in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or S3 Intelligent-Tiering storage classes, a retrieval-requests quota is applied for your AWS account. S3 Glacier supports restore requests at a rate of 1,000 transactions per second. If this rate is exceeded otherwise valid requests are throttled or rejected and Amazon S3 returns a `ThrottlingException` error. You can use S3 Batch Operations to retrieve many objects with a single request, which fully utilizes the restore request rate available in your account. For more information, see Performing object operations in bulk with Batch Operations.

After you initiate restore requests, S3 Glacier supports restoring large datasets at a throughput of up to 1–2 petabytes per day per customer account. For any retrieval option, objects larger than 5 terabytes will take longer to be restored with up to 300 megabytes per second of retrieval throughput. For example, a 50-terabyte S3 Glacier Flexible Retrieval object could take up to 48 hours to complete. If you require increased restoration limits, you can contact AWS Support.

Provisioned capacity

Provisioned capacity helps ensure that your retrieval capacity for Expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. Each unit of capacity provides that at least

three Expedited retrievals can be performed every 5 minutes, and it provides up to 300 megabytes per second of retrieval throughput.

Without provisioned capacity, Expedited retrievals might not be accepted during periods of high demand. For predictable, fast access to more of your data, consider using the S3 Glacier Instant Retrieval storage class.

Provisioned capacity units are allocated to an AWS account. Thus, the requester of the Expedited data retrieval should purchase the provisioned capacity unit, not the bucket owner.

You can purchase provisioned capacity by using the Amazon S3 console, the Amazon Glacier console, the Purchase Provisioned Capacity REST API operation, the AWS SDKs, or the AWS CLI. For provisioned capacity pricing information, see Amazon S3 pricing.

Restoring an archived object

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

Amazon S3 objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not immediately accessible. To access an object in these storage classes, you must restore a temporary copy of the object to its S3 bucket for a specified duration (number of days). If you want a permanent copy of the object, restore the object, and then create a copy of it in your Amazon S3 bucket. Copying restored objects isn't supported in the Amazon S3 console. For this type of copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API. Unless you make a copy and change its storage class, the object will still be stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For information about using these storage classes, see Storage classes for rarely accessed objects.

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a restore request and wait until the object is moved into the Frequent Access tier. When you restore an object from the Archive Access tier or Deep Archive Access tier, the object

moves back into the Frequent Access tier. For information about using these storage classes, see Storage class for automatically optimizing data with changing or unknown access patterns.

For general information about archived objects, see Working with archived objects.

> **Note**
>
> - When you restore an archived object from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, you pay for both the archived object and the copy that you restored temporarily.
> - When you restore an object from S3 Intelligent-Tiering, there are no retrieval charges for Standard or Bulk retrievals.
> - Subsequent restore requests called on archived objects that have already been restored are billed as GET requests. For information about pricing, see Amazon S3 pricing.

Restoring an archived object

You can restore an archived object by using the Amazon S3 console, the Amazon S3 REST API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), or S3 Batch Operations.

Using the S3 console

Restore objects using the Amazon S3 console

Use the following procedure to Restore an object that has been archived to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, or the S3 Intelligent-Tiering Archive Access or Deep Archive Access storage tiers.

To restore an archived object

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object or objects that you want to restore, choose **Actions**, and then choose **Initiate restore**.

5. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, enter the number of days that you want your archived data to be accessible in the **Number of days that the restored copy is available** box.
6. For **Retrieval tier**, do one of the following:

   - Choose **Bulk retrieval** or **Standard retrieval**, and then choose **Initiate restore**.
   - Choose **Expedited retrieval** (available only for S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering Archive Access). If you're restoring an object in S3 Glacier Flexible Retrieval, you can choose whether to buy provisioned capacity for your Expedited retrieval. If you want to purchase provisioned capacity, proceed to the next step. If you don't, choose **Initiate restore**.

   > **Note**
   >
   > Objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers are automatically restored to the Frequent Access tier.

7. (Optional) If you're restoring an object in S3 Glacier Flexible Retrieval and you chose **Expedited retrieval**, you can choose whether to buy provisioned capacity. Provisioned capacity is available only for objects in S3 Glacier Flexible Retrieval. If you already have provisioned capacity, choose **Initiate restore** to start a provisioned retrieval.

   If you have provisioned capacity, all of your Expedited retrievals are served by your provisioned capacity. For more information, see Provisioned capacity.

   - If you don't have provisioned capacity and you don't want to buy it, choose **Initiate restore**.
   - If you don't have provisioned capacity, but you want to buy provisioned capacity units (PCUs), choose **Purchase PCUs**. In the **Purchase PCUs** dialog box, choose how many PCUs you want to buy, confirm your purchase, and then choose **Purchase PCUs**. When you get the **Purchase succeeded** message, choose **Initiate restore** to start provisioned retrieval.

Using the AWS CLI

Restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive

The following example uses the `restore-object` command to restore the object *`dir1/example.obj`* in the bucket *`amzn-s3-demo-bucket`* for 25 days.

```
aws s3api restore-object --bucket amzn-s3-demo-bucket --key dir1/example.obj --restore-request '{"Days":25,"GlacierJobParameters":{"Tier":"Standard"}}'
```

If the JSON syntax used in the example results in an error on a Windows client, replace the restore request with the following syntax:

```
--restore-request Days=25,GlacierJobParameters={"Tier"="Standard"}
```

Restore objects from S3 Intelligent-Tiering Archive Access and Deep Archive Access

The following example uses the `restore-object` command to restore the object *dir1/example.obj* in the bucket *amzn-s3-demo-bucket* to the Frequent Access tier.

```
aws s3api restore-object --bucket amzn-s3-demo-bucket --key dir1/example.obj --restore-request '{}'
```

> **Note**
>
> Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the `Days` value.

Monitor restore status

To monitor the status of your `restore-object` request, use the following `head-object` command:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key dir1/example.obj
```

For more information, see restore-object in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to initiate the restoration of an archived object. For more information, see RestoreObject in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to restore archived objects in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with the AWS SDKs, see Code examples in the *Amazon S3 API Reference*.

Using S3 Batch Operations

To restore more than one archived object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

To create a Batch Operations job, you must have a manifest that contains only the objects that you want to restore. You can create a manifest by using S3 Inventory, or you can supply a CSV file with the necessary information. For more information, see the section called “Specifying a manifest”.

Before creating and running S3 Batch Operations jobs, you must grant permissions to Amazon S3 to perform S3 Batch Operations on your behalf. For the required permissions, see the section called “Granting permissions”.

> **Note**
>
> Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects *or* on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.
>
> For more information about using Batch Operations to restore archive objects, see the section called “Restore objects”.

To create an S3 Initiate Restore Object Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.
5. Under **Manifest format**, choose the type of manifest to use.
   - If you choose **S3 inventory report**, enter the path to the `manifest.json` object that Amazon S3 generated as part of the CSV-formatted inventory report. If you want to use a

manifest version other than the most recent, enter the version ID for the `manifest.json` object.

- If you choose **CSV**, enter the path to a CSV-formatted manifest object. The manifest object must follow the format described in the console. If you want to use a version other than the most recent, you can optionally include the version ID for the manifest object.

6. Choose **Next**.
7. In the **Operation** section, choose **Restore**.
8. In the **Restore** section, for **Restore source**, choose either **Glacier Flexible Retrieval or Glacier Deep Archive** or **Intelligent-Tiering Archive Access tier or Deep Archive Access tier**.

   If you chose **Glacier Flexible Retrieval or Glacier Deep Archive**, enter a number for **Number of days that the restored copy is available**.

   For **Retrieval tier**, choose the tier that you want to use.
9. Choose **Next**.
10. On the **Configure additional options** page, fill out the following sections:

    - In the **Additional options** section, provide a description for the job and specify a priority number for the job. Higher numbers indicate a higher priority. For more information, see the section called "Assigning job priority".
    - In the **Completion report** section, select whether Batch Operations should create a completion report. For more information about completion reports, see the section called "Completion reports".
    - In the **Permissions** section, you must grant permissions to Amazon S3 to perform Batch Operations on your behalf. For the required permissions, see the section called "Granting permissions".
    - (Optional) In the **Job tags** section, add tags in key-value pairs. For more information, see the section called "Using tags".

    When you're finished, choose **Next**.
11. On the **Review** page, verify the settings. If you need to make changes, choose **Previous**. Otherwise, choose **Create job**.

For more information about Batch Operations, see Restore objects with Batch Operations and Creating an S3 Batch Operations job.

Checking the restore status and expiration date

You can check the status of a restore request or the expiration date by using the Amazon S3 console, Amazon S3 Event Notifications, the AWS CLI, or the Amazon S3 REST API.

> **Note**
>
> Objects restored from the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are stored only for the number of days that you specify. The following procedures return the expiration date for these copies.
> Objects restored from the S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tiers don't have expiration dates and instead are moved back to the Frequent Access tier.

Using the S3 console

To check an object's restore status and expiration date in the Amazon S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the object that you are restoring.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears.

   - If the restoration isn't finished, a section says **Restoration in progress**.
   - If the restoration is finished, a section says **Restoration complete**. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, this section also displays the **Restoration expiry date**. Amazon S3 will remove the restored copy of your archived object on this date.

Using Amazon S3 Event Notifications

You can be notified of object restoration completion by using the `s3:ObjectRestore:Completed` action with the Amazon S3 Event Notifications feature. For

more information about enabling event notifications, see Enabling notifications by using Amazon SQS, Amazon SNS, and AWS Lambda. For more information about the various `ObjectRestore` event types, see the section called "Supported event types for SQS, SNS, and Lambda".

Using the AWS CLI

Check an object's restore status and expiration date with the AWS CLI

The following example uses the `head-object` command to view metadata for the object *`dir1/example.obj`* in the bucket *`amzn-s3-demo-bucket`*. When you run this command on an object being restored Amazon S3 returns if the restore is ongoing and (if applicable) the expiration date.

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key dir1/example.obj
```

Expected output (restore ongoing):

```
{
    "Restore": "ongoing-request=\"true\"",
    "LastModified": "2020-06-16T21:55:22+00:00",
    "ContentLength": 405,
    "ETag": "\"b662d79adeb7c8d787ea7eafb9ef6207\"",
    "VersionId": "wbYaE2vtOV0iIBXrOqGAJt3fP1cHB8Wi",
    "ContentType": "binary/octet-stream",
    "ServerSideEncryption": "AES256",
    "Metadata": {},
    "StorageClass": "GLACIER"
}
```

Expected output (restore finished):

```
{
    "Restore": "ongoing-request=\"false\", expiry-date=\"Wed, 12 Aug 2020 00:00:00 GMT
\"",
    "LastModified": "2020-06-16T21:55:22+00:00",
    "ContentLength": 405,
    "ETag": "\"b662d79adeb7c8d787ea7eafb9ef6207\"",
    "VersionId": "wbYaE2vtOV0iIBXrOqGAJt3fP1cHB8Wi",
    "ContentType": "binary/octet-stream",
    "ServerSideEncryption": "AES256",
    "Metadata": {},
    "StorageClass": "GLACIER"
```

```
}
```

For more information about `head-object`, see head-object in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to retrieve object metadata. To check the restoration status and expiration date of an archived object using the REST API, see HeadObject in the *Amazon Simple Storage Service API Reference*.

Upgrading the speed of an in-progress restore

You can upgrade the speed of your restoration while it is in progress.

To upgrade an in-progress restore to a faster tier

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears. On the object's details page, choose **Upgrade retrieval tier**. For information about checking the restoration status of an object, see Checking the restore status and expiration date.
5. Choose the tier that you want to upgrade to, and then choose **Initiate restore**.

Managing the lifecycle of objects

S3 Lifecycle helps you store objects cost effectively throughout their lifecycle by transitioning them to lower-cost storage classes, or, deleting expired objects on your behalf. To manage the lifecycle of your objects, create an *S3 Lifecycle configuration* for your bucket. An S3 Lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. There are two types of actions:

- **Transition actions** – These actions define when objects transition to another storage class. For example, you might choose to transition objects to the S3 Standard-IA storage class 30 days after creating them, or archive objects to the S3 Glacier Flexible Retrieval storage class one year after creating them. For more information, see Understanding and managing Amazon S3 storage classes.

There are costs associated with lifecycle transition requests. For pricing information, see Amazon S3 pricing.

- **Expiration actions** – These actions define when objects expire. Amazon S3 deletes expired objects on your behalf. For example, you might to choose to expire objects after they have been stored for a regulatory compliance period. For more information, see Expiring objects.

  There are potential costs associated with lifecycle expiration only when you expire objects in a storage class with a minimum storage duration. For more information, see Minimum storage duration charge.

> **Important**
>
> **General purpose buckets** — You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

> **Note**
>
> S3 Lifecycle does not independently manage annotations. Annotation storage is always billed at S3 Standard rates in Frequent Access storage, regardless of the parent object's storage class. When a Lifecycle rule expires an object, all annotations associated with that object version are deleted.

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old.

Changes in billing

If there is any delay between when an object becomes eligible for a lifecycle action and when Amazon S3 transfers or expires your object, billing changes are applied as soon as the object becomes eligible for the lifecycle action. For example, if an object is scheduled to expire and

Amazon S3 doesn't immediately expire the object, you won't be charged for storage after the expiration time.

The one exception to this behavior is if you have a lifecycle rule to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about S3 Lifecycle rules, see Lifecycle configuration elements.

> **Note**
>
> There are no data retrieval charges for lifecycle transitions. However, there are per-request ingestion charges when using PUT, COPY, or lifecycle rules to move data into any S3 storage class. Consider the ingestion or transition cost before moving objects into any storage class. For more information about cost considerations, see Amazon S3 pricing.

Monitoring the effect of lifecycle rules

To monitor the effect of updates made by active lifecycle rules, see the section called "How do I monitor the actions taken by my lifecycle rules?".

Managing the complete lifecycle of objects

With S3 Lifecycle configuration rules you can tell Amazon S3 to transition objects to less-expensive storage classes, archive or delete them. For example:

- If you upload periodic logs to a bucket, your application might need them for a week or a month. After that, you might want to delete them.
- Some documents are frequently accessed for a limited period of time. After that, they are infrequently accessed. At some point, you might not need real-time access to them, but your organization or regulations might require you to archive them for a specific period. After that, you can delete them.
- You might upload some types of data to Amazon S3 primarily for archival purposes. For example, you might archive digital media, financial, and healthcare records, raw genomics sequence data, long-term database backups, and data that must be retained for regulatory compliance.

By combining S3 Lifecycle actions to manage an object's complete lifecycle. For example, suppose that the objects you create have a well-defined lifecycle. Initially, the objects are frequently

accessed for a period of 30 days. Then, objects are infrequently accessed for up to 90 days. After that, the objects are no longer needed, so you might choose to archive or delete them.

In this scenario, you can create an S3 Lifecycle rule in which you specify the initial transition action to S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage, another transition action to S3 Glacier Flexible Retrieval storage for archiving, and an expiration action. As you move the objects from one storage class to another, you save on storage costs. For more information about cost considerations, see Amazon S3 pricing.

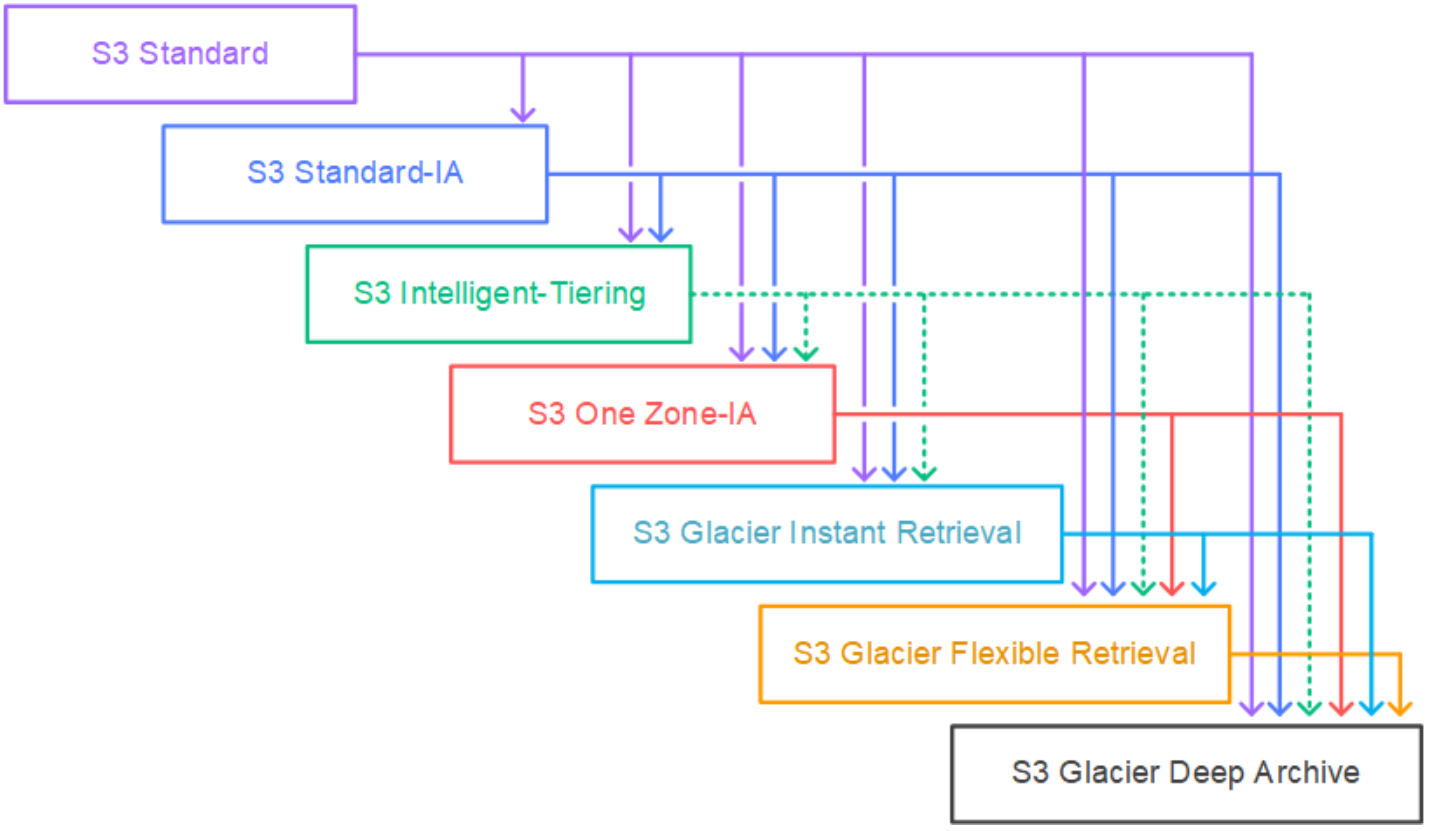
Transitioning objects using Amazon S3 Lifecycle

You can add transition actions to an S3 Lifecycle configuration to tell Amazon S3 to move objects to another Amazon S3 storage class. For more information about storage classes, see Understanding and managing Amazon S3 storage classes. Some examples of when you might use S3 Lifecycle configurations in this way include the following:



- When you know that objects are infrequently accessed, you might transition them to the S3 Standard-IA storage class.
- You might want to archive objects that you don't need to access in real time to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

> **Note**
>
> Encrypted objects remain encrypted throughout the storage class transition process.

Supported transitions

In an S3 Lifecycle configuration, you can define rules to transition objects from one storage class to another to save on storage costs. When you don't know the access patterns of your objects, or if your access patterns are changing over time, you can transition the objects to the S3 Intelligent-Tiering storage class for automatic cost savings. For information about storage classes, see Understanding and managing Amazon S3 storage classes.

Amazon S3 supports a waterfall model for transitioning between storage classes, as shown in the following diagram.

Supported lifecycle transitions

Amazon S3 supports the following lifecycle transitions between storage classes using an S3 Lifecycle configuration.

- The S3 Standard storage class to the S3 Standard-IA, S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Intelligent-Tiering storage class can transition to different storage classes depending on the S3 Intelligent-Tiering access tier. The following transitions are possible for each access tier.
  - Frequent Access tier or Infrequent Access tier to S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
  - Archive Instant Access tier to S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
  - Archive Access tier to S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
  - Deep Archive Access tier to S3 Glacier Deep Archive storage classes.
- The S3 One Zone-IA storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Instant Retrieval storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Flexible Retrieval storage class to the S3 Glacier Deep Archive storage class.

> **Note**
>
> For versioning enabled or versioning suspended buckets, you can't transition objects with a `Pending` or `Failed` replication status.

Constraints and considerations for transitions

Lifecycle storage class transitions have the following constraints:

Objects smaller than 128 KB will not transition by default to any storage class

Amazon S3 applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitioned to any storage class. We don't recommend transitioning objects less than 128 KB because you are charged a transition request for each object. This means, for smaller objects, the transition costs can outweigh the storage savings. For more information about transition request costs, see **Requests & data retrievals** on the **Storage & requests** tab of the Amazon S3 pricing page.

To allow smaller objects to transition, you can add an object size filter to your Lifecycle transition rules that specifies a custom minimum size (`ObjectSizeGreaterThan`) or maximum size (`ObjectSizeLessThan`). For more information, see Example: Allowing objects smaller than 128 KB to be transitioned.

> **Note**
>
> In September 2024 Amazon S3 updated the default transition behavior for small objects, as follows:
>
> - **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.
> - **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.
>
> Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case requires, you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-default-minimum-object-size` header in a PutBucketLifecycleConfiguration request.

You are charged for transitioning objects before their minimum storage duration

Certain storage classes have a minimum object storage duration. If you transition objects out of these storage classes before the minimum duration, you are charged for the remainder of that duration. For more information on which storage classes have minimum storage durations, see Comparing the Amazon S3 storage classes.

You can't create a single Lifecycle rule that transitions objects from one storage class to another before the minimum storage duration period has passed.

For example, S3 Glacier Instant Retrieval has a minimum storage duration of 90 days. You can't specify a lifecycle rule that transitions objects to S3 Glacier Instant Retrieval after 4 days, and

then transitions objects to S3 Glacier Deep Archive after 20 days. In this case the S3 Glacier Deep Archive transition must occur after at least 94 days.

You can specify two rules to accomplish this, but you pay the minimum duration storage charges. For more information about cost considerations, see Amazon S3 pricing.

For more information about creating a S3 Lifecycle, see Setting an S3 Lifecycle configuration on a bucket.

Tag-based filters and eligibility evaluation

S3 Lifecycle evaluates objects against tag-based filters daily. When an object matches a tag-based transition rule, Amazon S3 queues the action for asynchronous processing. At execution time, Amazon S3 re-evaluates the object's current tags. If the triggering tag is no longer present when the action executes, the transition does not proceed.

Because the time between evaluation and execution is not deterministic, removing a tag does not guarantee an immediate cancellation — the action may execute before the tag removal is observed, or the tag removal may take effect before the next evaluation cycle.

To reliably prevent a transition after tagging an object, wait for a Lifecycle Event Notification confirming the action completed before removing the tag. If you need to prevent a transition before it executes, remove the tag rather than disabling the rule (rule policy updates can take up to 15 minutes to propagate).

Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival)

By using an S3 Lifecycle configuration, you can transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes for archiving.

Before you archive objects, review the following sections for relevant considerations.

General considerations

The following are the general considerations for you to consider before you archive objects:

- Encrypted objects remain encrypted throughout the storage class transition process.
- Objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not available in real time.

Archived objects are Amazon S3 objects, but before you can access an archived object, you must first restore a temporary copy of it. The restored object copy is available only for the duration that you specify in the restore request. After that, Amazon S3 deletes the temporary copy, and the object remains archived in S3 Glacier Flexible Retrieval.

You can restore an object by using the Amazon S3 console or programmatically by using the AWS SDK wrapper libraries or the Amazon S3 REST API in your code. For more information, see Restoring an archived object.

- Objects that are stored in the S3 Glacier Flexible Retrieval storage class can only be transitioned to the S3 Glacier Deep Archive storage class.

  You can use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Flexible Retrieval to the S3 Glacier Deep Archive storage class only. If you want to change the storage class of an object that is stored in S3 Glacier Flexible Retrieval to a storage class other than S3 Glacier Deep Archive, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, or Reduced Redundancy as the storage class.

- The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

  You cannot use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Deep Archive to any other storage class. If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

> **Note**
>
> The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

The objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are visible and available only through Amazon S3. They are not available through the separate Amazon Glacier service.

These are Amazon S3 objects, and you can access them only by using the Amazon S3 console or the Amazon S3 API. You cannot access the archived objects through the separate Amazon Glacier console or the Amazon Glacier API.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – When you transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a fixed amount of storage is added to each object to accommodate metadata for managing the object.
  - For each object archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. Amazon S3 stores this metadata so that you can get a real-time list of your archived objects by using the Amazon S3 API. For more information, see Get Bucket (List Objects). You are charged S3 Standard rates for this additional storage.
  - For each object that is archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rates for this additional storage.

  If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.
- **Number of days you plan to keep objects archived** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep Archive. Deleting data that is archived to Amazon Glacier doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges a prorated early deletion

fee. For information about the early deletion fee, see the "How am I charged for deleting objects from Amazon Glacier that are less than 90 days old?" question on the Amazon S3 FAQ.

- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive transition request charges** – Each object that you transition to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class constitutes one transition request. There is a cost for each such request. If you plan to transition a large number of objects, consider the request costs. If you are archiving a mix of objects that includes small objects, especially those under 128KB, we recommend using the lifecycle object size filter to filter out small objects from your transition to reduce request costs.
- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive data restore charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are designed for long-term archival of data that you access infrequently. For information about data restoration charges, see the "How much does it cost to retrieve data from Amazon Glacier?" question on the Amazon S3 FAQ. For information about how to restore data from Amazon Glacier, see Restoring an archived object.

> **Note**
>
> S3 Lifecycle transitions objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive asynchronously. There might be a delay between the transition date in the S3 Lifecycle configuration rule and the date of the physical transition. You are charged at the destination storage class rate (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive) starting from the date the lifecycle rule is satisfied, even if the physical transition has not yet occurred. The minimum storage duration charges (90 days for S3 Glacier Flexible Retrieval, 180 days for S3 Glacier Deep Archive) and the per-object storage overhead (40 KB total, of which 8 KB is charged at S3 Standard rates and 32 KB at the destination Glacier rate) also begin at this point. The only exception is transitions to S3 Intelligent-Tiering, where billing changes occur after the physical transition completes. For more information, see Changes in billing.

The Amazon S3 product detail page provides pricing information and example calculations for archiving Amazon S3 objects. For more information, see the following topics:

- "How is my storage charge calculated for Amazon S3 objects archived to Amazon Glacier?" on the Amazon S3 FAQ.
- "How am I charged for deleting objects from Amazon Glacier that are less than 90 days old?" on the Amazon S3 FAQ.

- "How much does it cost to retrieve data from Amazon Glacier?" on the Amazon S3 FAQ.
- Amazon S3 pricing for storage costs for the different storage classes.

Restoring archived objects

Archived objects aren't accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A HeadObject or GetObject API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

> **Note**
>
> When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see Amazon S3 pricing.

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see Restoring an archived object.

Expiring objects

You can add expiration actions to an S3 Lifecycle configuration to tell Amazon S3 to delete objects at the end of their lifetime. When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 takes an `Expiration` action based on which S3 Versioning state the bucket is in:

- **Nonversioned bucket** – Amazon S3 queues the object for removal and removes it asynchronously, permanently removing the object.
- **Versioning-enabled bucket** – If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.
- **Versioning-suspended bucket** – Amazon S3 creates a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the `Expiration` action. For versioning-enabled or versioning-suspended buckets, the following applies:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the `Expiration` action to direct Amazon S3 to remove any expired object delete markers. For example, see Removing expired object delete markers in a versioning-enabled bucket.
- You can use the `NoncurrentVersionExpiration` action element to direct Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects can't be recovered. You can base this expiration on a certain number of days since the objects became noncurrent. In addition to the number of days, you can also provide a maximum number of noncurrent versions to retain (between 1 and 100). This value specifies how many newer noncurrent versions must exist before Amazon S3 can perform the associated action on a given version. To specify the maximum number of noncurrent versions, you must also provide a `Filter` element. If you don't specify a `Filter` element, Amazon S3 generates an `InvalidRequest` error when you provide a maximum number of noncurrent versions. For more information about using the `NoncurrentVersionExpiration` action element, see the section called “Elements to describe lifecycle actions”.
- Amazon S3 doesn't take any action on noncurrent versions of objects that have the S3 Object Lock configuration applied.
- For objects with a `Pending` or `Failed` replication status, Amazon S3 doesn't take any action on current or non-current versions of objects.

For more information, see Retaining multiple versions of objects with S3 Versioning.

> **Important**
>
> An object is eligible for only one S3 Lifecycle action per day. When multiple rules match, Amazon S3 applies the least costly action.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

Important

You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

Tag-based filters and eligibility evaluation

S3 Lifecycle evaluates objects against tag-based filters daily. When an object matches a tag-based expiration rule, Amazon S3 queues the action for asynchronous processing. At execution time, Amazon S3 re-evaluates the object's current tags. If the triggering tag is no longer present when the action executes, the expiration does not proceed.

To reliably confirm an expiration occurred before removing the tag, wait for a Lifecycle Event Notification. If you need to prevent an expiration before it executes, remove the tag (tag updates take effect faster than rule policy changes, which can take up to 15 minutes to propagate).

How to find when objects will expire

To find when the current version of an object is scheduled to expire, use the HeadObject or GetObject API operation. These API operations return response headers that provide the date and time at which the current version of the object is no longer cacheable.

> **Note**
>
> - There may be a delay between the expiration date and the date at which Amazon S3 removes an object. You are not charged for expiration or the storage time associated with an object that has expired. For more information, including guidance for deletions that must meet a deadline, see Transition or expiration delay.
> - Before updating, disabling, or deleting Lifecycle rules, use the `LIST` API operations (such as ListObjectsV2, ListObjectVersions, and ListMultipartUploads) or Cataloging and analyzing your data with S3 Inventory to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases.

Minimum storage duration charge

If you create an S3 Lifecycle expiration rule that causes objects that have been in S3 Standard-IA or S3 One Zone-IA storage for less than 30 days to expire, you are charged for 30 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Flexible Retrieval storage for less than 90 days to expire, you are charged for 90 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Deep Archive storage for less than 180 days to expire, you are charged for 180 days.

For more information, see Amazon S3 pricing.

Setting an S3 Lifecycle configuration on a bucket

You can set an Amazon S3 Lifecycle configuration on a bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API. For information about S3 Lifecycle configuration, see Managing the lifecycle of objects.

> **Note**
>
> To view or edit the lifecycle configuration for a directory bucket, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API. For more information, see Working with S3 Lifecycle for directory buckets.

In your S3 Lifecycle configuration, you use *lifecycle rules* to define actions that you want Amazon S3 to take during an object's lifetime. For example, you can define rules to transition objects to another storage class, archive objects, or expire (delete) objects after a specified period of time.

S3 Lifecycle considerations

Before you set a lifecycle configuration, note the following:

Lifecycle configuration propagation delay

When you add an S3 Lifecycle configuration to a bucket, there is usually some lag before a new or updated Lifecycle configuration is fully propagated to all the Amazon S3 systems. Expect a delay of a few minutes before the configuration fully takes effect. This delay can also occur when you delete an S3 Lifecycle configuration.

Transition or expiration delay

There's a delay between when a lifecycle rule is satisfied and when the action for the rule is completed. For example, suppose that a set of objects is expired by a lifecycle rule on January 1. Even though the expiration rule has been satisfied on January 1, Amazon S3 might not actually delete these objects until days or even weeks later. This delay occurs because S3 Lifecycle queues objects for transitions or expirations asynchronously. S3 Lifecycle doesn't guarantee a completion time for transition or expiration actions. To track progress for your bucket, see How do I monitor the actions taken by my lifecycle rules? When you add or modify a Lifecycle rule, S3 Lifecycle may begin processing eligible objects immediately or with some delay. When S3 Lifecycle creates a delete marker or transitions an object, the timestamp is set to midnight UTC on the day the action occurred, regardless of the actual time the action was taken. A delay doesn't affect your bill. Changes in billing are applied when the object becomes eligible for the lifecycle action, even if the action isn't complete. The one exception is transitions to S3 Intelligent-Tiering, which are billed after the transition completes. For more information, see Changes in billing.

Note

We don't recommend relying on S3 Lifecycle alone for deletions that must complete by a fixed deadline, such as a regulatory or contractual data-retention requirement. Use an Cataloging and analyzing your data with S3 Inventory report with the Lifecycle Expiration Date field to identify objects that are past their expiration date but haven't been removed yet, and delete any objects that must be removed by your deadline.

Note

When a lifecycle rule is created or modified, objects that already meet the eligibility criteria may be processed immediately.

Updating, disabling, or deleting lifecycle rules

When you disable or delete lifecycle rules, Amazon S3 stops scheduling new objects for deletion or transition after a small delay. Any objects that were already scheduled are unscheduled and are not deleted or transitioned.

Note

Before updating, disabling, or deleting lifecycle rules, use the `LIST` API operations (such as ListObjectsV2, ListObjectVersions, and ListMultipartUploads) or Cataloging and analyzing your data with S3 Inventory to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases. If you're experiencing any issues with updating, disabling, or deleting lifecycle rules, see Troubleshooting Amazon S3 Lifecycle issues.

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

Monitoring the effect of lifecycle rules

To monitor the effect of updates made by active lifecycle rules, see the section called "How do I monitor the actions taken by my lifecycle rules?"

Changes in billing

There might be a lag between when the Lifecycle configuration rules are satisfied and when the action triggered by satisfying the rule is taken. However, changes in billing happen as soon as the Lifecycle configuration rule is satisfied, even if the action isn't yet taken.

For example, after the object expiration time, you aren't charged for storage, even if the object isn't deleted immediately. Likewise, as soon as the object transition time elapses, you're charged S3 Glacier Flexible Retrieval storage rates, even if the object isn't immediately transitioned to the S3 Glacier Flexible Retrieval storage class.

However, lifecycle transitions to the S3 Intelligent-Tiering storage class are the exception. Changes in billing don't happen until after the object has transitioned into the S3 Intelligent-Tiering storage class.

For transitions to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive, the per-object storage overhead (40 KB per object) and minimum storage duration charges (90 days for S3 Glacier Flexible Retrieval, 180 days for S3 Glacier Deep Archive) also begin when the lifecycle rule is satisfied, regardless of when the physical transition occurs. For more information about Glacier storage overhead, see Cost considerations.

Multiple or conflicting rules

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

How to set an S3 Lifecycle configuration

You can set an Amazon S3 Lifecycle configuration on a general purpose bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

For information about AWS CloudFormation templates and examples, see Working with AWS CloudFormation templates and AWS::S3::Bucket in the *CloudFormation User Guide*.

Using the S3 console

You can define lifecycle rules for all objects or a subset of objects in a bucket by using a shared prefix (objects names that begin with a common string) or a tag. In your lifecycle rule, you can define actions specific to current and noncurrent object versions. For more information, see the following:

- Managing the lifecycle of objects
- Retaining multiple versions of objects with S3 Versioning

To create a lifecycle rule

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a lifecycle rule for.
4. Choose the **Management** tab, and choose **Create lifecycle rule**.
5. In **Lifecycle rule name**, enter a name for your rule.

   The name must be unique within the bucket.
6. Choose the scope of the lifecycle rule:

   - To apply this lifecycle rule to *all objects with a specific prefix or tag*, choose **Limit the scope to specific prefixes or tags**.
     - To limit the scope by prefix, in **Prefix**, enter the prefix.
     - To limit the scope by tag, choose **Add tag**, and enter the tag key and value.

     For more information about object name prefixes, see Naming Amazon S3 objects. For more information about object tags, see Tagging your objects.

- To apply this lifecycle rule to *all objects in the bucket*, choose **This rule applies to *all* objects in the bucket**, and then choose **I acknowledge that this rule applies to all objects in the bucket**.

7. To filter a rule by object size, you can select **Specify minimum object size**, **Specify maximum object size**, or both options.

   - When you're specifying a value for **Minimum object size** or **Maximum object size**, the value must be larger than 0 bytes and up to 50 TB. You can specify this value in bytes, KB, MB, or GB.
   - When you're specifying both values, the maximum object size must be larger than the minimum object size.

   > **Note**
   >
   > The **Minimum object size** and **Maximum object size** filters exclude the specified values. For example, if you set a filter to expire objects that have a **Minimum object size** of 128 KB, objects that are exactly 128 KB don't expire. Instead, the rule applies only to objects that are greater than 128 KB in size.

8. Under **Lifecycle rule actions**, choose the actions that you want your lifecycle rule to perform:

   - Transition *current* versions of objects between storage classes
   - Transition *previous* versions of objects between storage classes
   - Expire *current* versions of objects

   > **Note**
   >
   > For buckets that don't have S3 Versioning enabled, expiring current versions causes Amazon S3 to permanently delete the objects. For more information, see the section called “Lifecycle actions and bucket versioning state”.

   - Permanently delete *previous* versions of objects
   - Delete expired delete markers or incomplete multipart uploads

   Depending on the actions that you choose, different options appear.

9. To transition *current* versions of objects between storage classes, under **Transition current versions of objects between storage classes**, do the following:

   a. In **Storage class transitions**, choose the storage class to transition to. For a list of possible transitions, see the section called "Supported lifecycle transitions". You can choose from the following storage classes:

      - S3 Standard-IA
      - S3 Intelligent-Tiering
      - S3 One Zone-IA
      - S3 Glacier Instant Retrieval
      - S3 Glacier Flexible Retrieval
      - S3 Glacier Deep Archive

   b. In **Days after object creation**, enter the number of days after creation to transition the object.

   For more information about storage classes, see Understanding and managing Amazon S3 storage classes. You can define transitions for current or previous object versions or for both current and previous versions. Versioning enables you to keep multiple versions of an object in one bucket. For more information about versioning, see Using the S3 console.

   > **Important**
   >
   > When you choose the S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Glacier Deep Archive storage class, your objects remain in Amazon S3. You cannot access them directly through the separate Amazon Glacier service. For more information, see Transitioning objects using Amazon S3 Lifecycle.

10. To transition *noncurrent* versions of objects between storage classes, under **Transition noncurrent versions of objects between storage classes**, do the following:

    a. In **Storage class transitions**, choose the storage class to transition to. For a list of possible transitions, see the section called "Supported lifecycle transitions". You can choose from the following storage classes:

       - S3 Standard-IA
       - S3 Intelligent-Tiering

- S3 One Zone-IA
- S3 Glacier Instant Retrieval
- S3 Glacier Flexible Retrieval
- S3 Glacier Deep Archive

b. In **Days after object becomes noncurrent**, enter the number of days after creation to transition the object.

11. To expire *current* versions of objects, under **Expire current versions of objects**, in **Number of days after object creation**, enter the number of days.

> **Important**
>
> In a nonversioned bucket, the expiration action results in Amazon S3 permanently removing the object. For more information about lifecycle actions, see Elements to describe lifecycle actions.

12. To permanently delete previous versions of objects, under **Permanently delete noncurrent versions of objects**, in **Days after objects become noncurrent**, enter the number of days. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**.
13. Under **Delete expired delete markers or incomplete multipart uploads**, choose **Delete expired object delete markers** and **Delete incomplete multipart uploads**. Then, enter the number of days after the multipart upload initiation that you want to end and clean up incomplete multipart uploads.

    For more information about multipart uploads, see Uploading and copying objects using multipart upload in Amazon S3.
14. Choose **Create rule**.

    If the rule does not contain any errors, Amazon S3 enables it, and you can see it on the **Management** tab under **Lifecycle rules**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Lifecycle configurations:

- `put-bucket-lifecycle-configuration`

- `get-bucket-lifecycle-configuration`
- `delete-bucket-lifecycle`

For instructions on setting up the AWS CLI, see Developing with Amazon S3 using the AWS CLI in the *Amazon S3 API Reference*.

The Amazon S3 Lifecycle configuration is an XML file. But when you're using the AWS CLI, you cannot specify the XML format. You must specify the JSON format instead. The following are example XML lifecycle configurations and the equivalent JSON configurations that you can specify in an AWS CLIcommand.

Consider the following example S3 Lifecycle configuration.

Example 1

Example

XML

```
<LifecycleConfiguration>
    <Rule>
        <ID>ExampleRule</ID>
        <Filter>
           <Prefix>documents/</Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>365</Days>
           <StorageClass>GLACIER</StorageClass>
        </Transition>
        <Expiration>
             <Days>3650</Days>
        </Expiration>
    </Rule>
</LifecycleConfiguration>
```

JSON

```
{
    "Rules": [
        {
```

```
            "Filter": {
                "Prefix": "documents/"
            },
            "Status": "Enabled",
            "Transitions": [
                {
                    "Days": 365,
                    "StorageClass": "GLACIER"
                }
            ],
            "Expiration": {
                "Days": 3650
            },
            "ID": "ExampleRule"
        }
    ]
}
```

Example 2

Example

XML

```
<LifecycleConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <Rule>
        <ID>id-1</ID>
        <Expiration>
            <Days>1</Days>
        </Expiration>
        <Filter>
            <And>
                <Prefix>myprefix</Prefix>
                <Tag>
                    <Key>mytagkey1</Key>
                    <Value>mytagvalue1</Value>
                </Tag>
                <Tag>
                    <Key>mytagkey2</Key>
                    <Value>mytagvalue2</Value>
                </Tag>
            </And>
        </Filter>
```

```
        <Status>Enabled</Status>
    </Rule>
</LifecycleConfiguration>
```

JSON

```
{
    "Rules": [
        {
            "ID": "id-1",
            "Filter": {
                "And": {
                    "Prefix": "myprefix",
                    "Tags": [
                        {
                            "Value": "mytagvalue1",
                            "Key": "mytagkey1"
                        },
                        {
                            "Value": "mytagvalue2",
                            "Key": "mytagkey2"
                        }
                    ]
                }
            },
            "Status": "Enabled",
            "Expiration": {
                "Days": 1
            }
        }
    ]
}
```

You can test the `put-bucket-lifecycle-configuration` as follows.

To test the configuration

1. Save the JSON Lifecycle configuration in a file (for example, *`lifecycle.json`*).
2. Run the following AWS CLI command to set the Lifecycle configuration on your bucket. Replace the *`user input placeholders`* with your own information.

```
$ aws s3api put-bucket-lifecycle-configuration  \
--bucket amzn-s3-demo-bucket  \
--lifecycle-configuration file://lifecycle.json
```

3. To verify, retrieve the S3 Lifecycle configuration by using the `get-bucket-lifecycle-configuration` AWS CLI command as follows:

```
$ aws s3api get-bucket-lifecycle-configuration  \
--bucket amzn-s3-demo-bucket
```

> **Important**
>
> The output of `get-bucket-lifecycle-configuration` includes `TransitionDefaultMinimumObjectSize` as a top-level field alongside `Rules`. This field is not part of the `LifecycleConfiguration` JSON schema accepted by `put-bucket-lifecycle-configuration`. If you use the GET output directly as the PUT input, the command fails with a validation error.
> To copy a lifecycle configuration between buckets, you must either remove `TransitionDefaultMinimumObjectSize` from the JSON file or use the `--query '{Rules: Rules}'` parameter with the GET command to extract only the rules. If you need to preserve the `TransitionDefaultMinimumObjectSize` value, pass it separately using the `--transition-default-minimum-object-size` parameter.

4. To delete the S3 Lifecycle configuration, use the `delete-bucket-lifecycle` AWS CLI command as follows:

```
aws s3api delete-bucket-lifecycle \
--bucket amzn-s3-demo-bucket
```

Using the AWS SDKs

Java

You can use the AWS SDK for Java to manage the S3 Lifecycle configuration of a bucket. For more information about managing S3 Lifecycle configuration, see Managing the lifecycle of objects.

> **Note**
>
> When you add an S3 Lifecycle configuration to a bucket, Amazon S3 replaces the bucket's current Lifecycle configuration, if there is one. To update a configuration, you retrieve it, make the desired changes, and then add the revised configuration to the bucket.

To manage lifecycle configuration using the AWS SDK for Java, you can:

- Add a Lifecycle configuration to a bucket.
- Retrieve the Lifecycle configuration and update it by adding another rule.
- Add the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing configuration.
- Retrieve the configuration again and verify that it has the right number of rules by printing the number of rules.
- Delete the Lifecycle configuration and verify that it has been deleted by attempting to retrieve it again.

For examples of how to set lifecycle configuration on a bucket with the AWS SDK for Java, see Set lifecycle configuration on a bucket in the *Amazon S3 API Reference*.

.NET

You can use the AWS SDK for .NET to manage the S3 Lifecycle configuration on a bucket. For more information about managing Lifecycle configuration, see Managing the lifecycle of objects.

> **Note**
>
> When you add a Lifecycle configuration, Amazon S3 replaces the existing configuration on the specified bucket. To update a configuration, you must first retrieve the Lifecycle configuration, make the changes, and then add the revised Lifecycle configuration to the bucket.

The following example shows how to use the AWS SDK for .NET to add, update, and delete a bucket's Lifecycle configuration. The code example does the following:

- Adds a Lifecycle configuration to a bucket.
- Retrieves the Lifecycle configuration and updates it by adding another rule.
- Adds the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing Lifecycle configuration.
- Retrieves the configuration again and verifies it by printing the number of rules in the configuration.
- Deletes the Lifecycle configuration and verifies the deletion.

For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class LifecycleTest
    {
        private const string bucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            AddUpdateDeleteLifecycleConfigAsync().Wait();
        }

        private static async Task AddUpdateDeleteLifecycleConfigAsync()
        {
            try
            {
                var lifeCycleConfiguration = new LifecycleConfiguration()
                {
                    Rules = new List<LifecycleRule>
```

```
                        {
                            new LifecycleRule
                            {
                                 Id = "Archive immediately rule",
                                 Filter = new LifecycleFilter()
                                 {
                                     LifecycleFilterPredicate = new
LifecyclePrefixPredicate()
                                     {
                                         Prefix = "glacierobjects/"
                                     }
                                 },
                                 Status = LifecycleRuleStatus.Enabled,
                                 Transitions = new List<LifecycleTransition>
                                 {
                                      new LifecycleTransition
                                      {
                                           Days = 0,
                                           StorageClass = S3StorageClass.Glacier
                                      }
                                  },
                            },
                            new LifecycleRule
                            {
                                 Id = "Archive and then delete rule",
                                  Filter = new LifecycleFilter()
                                 {
                                     LifecycleFilterPredicate = new
LifecyclePrefixPredicate()
                                     {
                                         Prefix = "projectdocs/"
                                     }
                                 },
                                 Status = LifecycleRuleStatus.Enabled,
                                 Transitions = new List<LifecycleTransition>
                                 {
                                      new LifecycleTransition
                                      {
                                           Days = 30,
                                           StorageClass =
S3StorageClass.StandardInfrequentAccess
                                      },
                                      new LifecycleTransition
                                      {
```

```
                                    Days = 365,
                                    StorageClass = S3StorageClass.Glacier
                                }
                            },
                            Expiration = new LifecycleRuleExpiration()
                            {
                                Days = 3650
                            }
                        }
                    }
                };

                // Add the configuration to the bucket.
                await AddExampleLifecycleConfigAsync(client,
lifeCycleConfiguration);

                // Retrieve an existing configuration.
                lifeCycleConfiguration = await RetrieveLifecycleConfigAsync(client);

                // Add a new rule.
                lifeCycleConfiguration.Rules.Add(new LifecycleRule
                {
                    Id = "NewRule",
                    Filter = new LifecycleFilter()
                    {
                        LifecycleFilterPredicate = new LifecyclePrefixPredicate()
                        {
                            Prefix = "YearlyDocuments/"
                        }
                    },
                    Expiration = new LifecycleRuleExpiration()
                    {
                        Days = 3650
                    }
                });

                // Add the configuration to the bucket.
                await AddExampleLifecycleConfigAsync(client,
lifeCycleConfiguration);

                // Verify that there are now three rules.
                lifeCycleConfiguration = await RetrieveLifecycleConfigAsync(client);
                Console.WriteLine("Expected # of rulest=3; found:{0}",
lifeCycleConfiguration.Rules.Count);
```

```
                // Delete the configuration.
                await RemoveLifecycleConfigAsync(client);

                // Retrieve a nonexistent configuration.
                lifeCycleConfiguration = await RetrieveLifecycleConfigAsync(client);

            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered ***. Message:'{0}' when writing
an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
        }

            await client.DeleteLifecycleConfigurationAsync(request);
        }
    }
}
```

Ruby

You can use the AWS SDK for Ruby to manage an S3 Lifecycle configuration on a bucket by using the class AWS::S3::BucketLifecycleConfiguration. For more information about managing S3 Lifecycle configuration, see Managing the lifecycle of objects.

Using the REST API

The following topics in the *Amazon Simple Storage Service API Reference* describe the REST API operations related to S3 Lifecycle configuration:

- PutBucketLifecycleConfiguration
- GetBucketLifecycleConfiguration
- DeleteBucketLifecycle

Troubleshooting S3 Lifecycle

For common issues that might occur when working with S3 Lifecycle, see the section called "Troubleshooting lifecycle issues".

How S3 Lifecycle interacts with other bucket configurations

In addition to S3 Lifecycle configurations, you can associate other configurations with your bucket. This section explains how S3 Lifecycle configuration relates to other bucket configurations.

S3 Lifecycle and S3 Versioning

You can add S3 Lifecycle configurations to unversioned buckets and versioning-enabled buckets. For more information, see Retaining multiple versions of objects with S3 Versioning.

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate lifecycle rules for current and noncurrent object versions.

For more information, see Lifecycle configuration elements.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

S3 Lifecycle and S3 Replication

When you have both S3 Replication and S3 Lifecycle enabled on a bucket, S3 Lifecycle blocks expiration and transition actions on objects with `PENDING` or `FAILED` replication status. This ensures that Lifecycle does not act on objects until they have successfully replicated to their destination bucket.

Objects transition to a `FAILED` replication state for issues such as missing replication role permissions, AWS Key Management Service (AWS KMS) permissions, or bucket permissions. For more information, see Troubleshooting replication.

Objects with `FAILED` replication status will continue to incur storage costs past their Lifecycle expiration or transition eligibility date until the replication issue is resolved. Once you fix the

underlying replication configuration or IAM permissions, new objects will replicate automatically. However, objects that already have `FAILED` replication status will not automatically retry—you must use S3 Batch Replication to replicate them, or delete them using S3 Batch Operations with AWS Lambda if no longer needed. After objects successfully replicate (or are deleted), Lifecycle will resume processing them according to your configured rules. To identify objects with `FAILED` replication status, you can use Amazon CloudWatch metrics (`OperationFailedReplication`) to monitor failure counts and trends at the bucket level, or use Amazon S3 Inventory reports, Amazon S3 API (`HeadObject` or `GetObject`), or Amazon S3 Event Notifications for object-level details.

S3 Lifecycle configuration on MFA-enabled buckets

S3 Lifecycle configuration on multi-factor authentication buckets configured for MFA delete isn't supported. For more information, see Configuring MFA delete.

S3 Lifecycle and logging

Amazon S3 Lifecycle actions aren't captured by AWS CloudTrail object level logging. CloudTrail captures API requests made to external Amazon S3 endpoints, whereas S3 Lifecycle actions are performed by using internal Amazon S3 endpoints.

You can enable Amazon S3 server access logs in an S3 bucket to capture S3 Lifecycle-related actions, such as object transitions to another storage class and object expirations that result in permanent deletion or logical deletion. For more information, see the section called “Logging server access”.

If you have logging enabled on your bucket, Amazon S3 server access logs report the results of the following operations.

Operation log	Description
`S3.EXPIRE.OBJECT`	Amazon S3 permanently deletes the object because of the lifecycle `Expiration` action.
`S3.CREATE.DELETEMARKER`	Amazon S3 logically deletes the current version by adding a delete marker in a versioning-enabled bucket.
`S3.TRANSITION_SIA.OBJECT`	Amazon S3 transitions the object to the S3 Standard-IA storage class.

Operation log	Description
S3.TRANSITION_ZIA.OBJECT	Amazon S3 transitions the object to the S3 One Zone-IA storage class.
S3.TRANSITION_INT.OBJECT	Amazon S3 transitions the object to the S3 Intelligent-Tiering storage class.
S3.TRANSITION_GIR.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Instant Retrieval storage class.
S3.TRANSITION.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Flexible Retrieval storage class.
S3.TRANSITION_GDA.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Deep Archive storage class.
S3.DELETE.UPLOAD	Amazon S3 aborts an incomplete multipart upload.

Note

Amazon S3 server access log records are delivered on a best-effort basis and can't be used for a complete accounting of all Amazon S3 requests.

Configuring S3 Lifecycle event notifications

To receive notice when Amazon S3 deletes an object or transitions it to another Amazon S3 storage class as the result of following an S3 Lifecycle rule, you can set up an Amazon S3 event notification.

You can receive notifications for the following S3 Lifecycle events:

- **Transition events** – By using the `s3:LifecycleTransition` event type, you can receive notification when an object is transitioned from one Amazon S3 storage class to another by an S3 Lifecycle configuration.
- **Expiration (delete) events** – By using the `LifecycleExpiration` event types, you can receive notifications whenever Amazon S3 deletes an object based on your S3 Lifecycle configuration.

  There are two expiration event types:

  - The `s3:LifecycleExpiration:Delete` event type notifies you when an object in an unversioned bucket is deleted. `s3:LifecycleExpiration:Delete` also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration.
  - The `s3:LifecycleExpiration:DeleteMarkerCreated` event type notifies you when S3 Lifecycle creates a delete marker after a current version of an object in a versioned bucket is deleted. S3 Lifecycle sets the delete marker's creation time to 00:00 UTC (midnight) of the current day. This creation time might differ from the event time in the `s3:LifecycleExpiration:DeleteMarkerCreated` notification that S3 sends. For more information, see the section called “Deleting object versions”.

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see Amazon S3 Event Notifications.

For instructions on how to configure Amazon S3 Event Notifications, see Enabling event notifications by using Amazon SQS, Amazon SNS, and AWS Lambda.

The following is an example of a message that Amazon S3 sends to publish an `s3:LifecycleExpiration:Delete` event. For more information, see the section called “Event message structure”.

```
{
   "Records":[
      {
         "eventVersion":"2.3",
         "eventSource":"aws:s3",
         "awsRegion":"us-west-2",
         "eventTime":"1970-01-01T00:00:00.000Z",
         "eventName":"LifecycleExpiration:Delete",
         "userIdentity":{
            "principalId":"s3.amazonaws.com"
         },
```

```
         "requestParameters":{
            "sourceIPAddress":"s3.amazonaws.com"
         },
         "responseElements":{
            "x-amz-request-id":"C3D13FE58DE4C810",
            "x-amz-id-2":"FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvANOjpD"
         },
         "s3":{
            "s3SchemaVersion":"1.0",
            "configurationId":"testConfigRule",
            "bucket":{
               "name":"amzn-s3-demo-bucket",
               "ownerIdentity":{
                  "principalId":"A3NL1KOZZKExample"
               },
               "arn":"arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "object":{
               "key":"expiration/delete",
               "sequencer":"0055AED6DCD90281E5",
            }
         }
      }
   ]
}
```

Messages that Amazon S3 sends to publish an `s3:LifecycleTransition` event also include the following information:

```
"lifecycleEventData":{
    "transitionEventData": {
        "destinationStorageClass": the destination storage class for the object
    }
}
```

Lifecycle configuration elements

A S3 Lifecycle configuration consist of Lifecycle rules that include various elements that describe the actions Amazon S3 takes during an object's lifetime. Each S3 bucket can have one lifecycle configuration assigned to it, which can contain up to 1,000 rules. You specify an Amazon S3

Lifecycle configuration as XML, consisting of one or more Lifecycle rules, where each rule consists of one or more elements.

```
<LifecycleConfiguration>
    <Rule>
         <Element>
    </Rule>
    <Rule>
         <Element>
         <Element>
    </Rule>
</LifecycleConfiguration>
```

Each rule consists of the following:

- Rule metadata that includes a rule ID, and a status that indicates whether the rule is enabled or disabled. If a rule is disabled, Amazon S3 doesn't perform any actions specified in the rule.
- A filter that identifies the objects to which the rule applies. You can specify a filter by using the object size, the object key prefix, one or more object tags, or a combination of filters.
- One or more transition or expiration actions with a date or a time period in the object's lifetime when you want Amazon S3 to perform the specified action.

Topics

- ID element
- Status element
- Filter element
- Elements to describe lifecycle actions
- Adding filters to Lifecycle rules

The following sections describe the XML elements in an S3 Lifecycle configuration. For example configurations, see Examples of S3 Lifecycle configurations.

ID element

Lifecycle configurations are set at the bucket level, with each bucket having its own lifecycle configuration. An S3 Lifecycle configuration can have up to 1,000 rules per bucket. This limit is not

adjustable. The <ID> element uniquely identifies a rule within a bucket's lifecycle configuration. ID length is limited to 255 characters.

Status element

The <Status> element value can be either Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform any of the actions defined in the rule.

Filter element

A S3 Lifecycle rule can apply to all or a subset of objects in a bucket based on the <Filter> element that you specify in the rule.

You can filter objects by key prefix, object tags, or a combination of both (in which case Amazon S3 uses a logical AND to combine the filters). For examples and more information about filters see, Adding filters to Lifecycle rules.

- **Specifying a filter by using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (logs/). For example, the Lifecycle rule applies to the objects logs/mylog.txt, logs/temp1.txt, and logs/test.txt. The rule does not apply to the object example.jpg.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
           <Prefix>logs/</Prefix>
        </Filter>
        transition/expiration actions
         ...
    </Rule>
    ...
</LifecycleConfiguration>
```

  If you want to apply a lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a lifecycle action for objects with the key prefixes projectA/ and projectB/, you specify two rules as follows:

```
<LifecycleConfiguration>
    <Rule>
```

```
        <Filter>
           <Prefix>projectA/</Prefix>
        </Filter>
        transition/expiration actions
         ...
    </Rule>

    <Rule>
        <Filter>
           <Prefix>projectB/</Prefix>
        </Filter>
        transition/expiration actions
         ...
    </Rule>
</LifecycleConfiguration>
```

For more information about object keys, see Naming Amazon S3 objects.

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (*key*) and value (*value*). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
           <Tag>
              <Key>key</Key>
              <Value>value</Value>
           </Tag>
        </Filter>
        transition/expiration actions
        ...
    </Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the <And> element, as shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
    <Rule>
      <Filter>
```

```
          <And>
             <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
             </Tag>
             <Tag>
                <Key>key2</Key>
                <Value>value2</Value>
             </Tag>
              ...
          </And>
      </Filter>
      transition/expiration actions
    </Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a <Key> element and no <Value> element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

> **Note**
>
> When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the <And> element, as follows:

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
          <And>
             <Prefix>key-prefix</Prefix>
             <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
```

```
            </Tag>
            <Tag>
               <Key>key2</Key>
               <Value>value2</Value>
            </Tag>
             ...
          </And>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- You can specify an **empty filter**, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

- To filter a rule by **object size**, you can specify a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes.

  Object size values are in bytes. By default, objects smaller than 128 KB will not be transitioned to any storage class, unless you specify a smaller minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`). For more information, see Example: Allowing objects smaller than 128 KB to be transitioned.

```
                    <LifecycleConfiguration>
    <Rule>
        <Filter>
            <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
        </Filter>
```

```
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

> **Note**
>
> The `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024 KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreaterThan` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an <And> element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
            <And>
                <Prefix>key-prefix</Prefix>
                <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
                <ObjectSizeLessThan>64000</ObjectSizeLessThan>
            </And>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

Elements to describe lifecycle actions

You can direct Amazon S3 to perform specific actions in an object's lifetime by specifying one or more of the following predefined actions in an S3 Lifecycle rule. The effect of these actions depends on the versioning state of your bucket.

- **`Transition` action element** – You specify the `Transition` action to transition objects from one storage class to another. For more information about transitioning objects, see Supported transitions. When a specified date or time period in the object's lifetime is reached, Amazon S3 performs the transition.

  For a versioned bucket (versioning-enabled or versioning-suspended bucket), the `Transition` action applies to the current object version. To manage noncurrent versions, Amazon S3 defines the `NoncurrentVersionTransition` action (described later in this topic).

- **`Expiration` action element** – The `Expiration` action expires objects identified in the rule and applies to eligible objects in any of the Amazon S3 storage classes. For more information about storage classes, see Understanding and managing Amazon S3 storage classes. Amazon S3 makes all expired objects unavailable. Whether the objects are permanently removed depends on the versioning state of the bucket.

  - **Nonversioned bucket** – The `Expiration` action results in Amazon S3 permanently removing the object.
  - **Versioned bucket** – For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the `Expiration` action. For versioning-enabled or versioning-suspended buckets, the following applies:
    - The `Expiration` action applies only to the current version (it has no impact on noncurrent object versions).
    - Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
    - If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the expiration action to direct Amazon S3 to remove any expired object delete markers. For an example, see Removing expired object delete markers in a versioning-enabled bucket.

    For more information, see Retaining multiple versions of objects with S3 Versioning.

    Also consider the following when setting up Amazon S3 to manage expiration:

    - **Versioning-enabled bucket**

If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.

- **Versioning-suspended bucket**

  In a versioning-suspended bucket, the expiration action causes Amazon S3 to create a delete marker with `null` as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

In addition, Amazon S3 provides the following actions that you can use to manage noncurrent object versions in a versioned bucket (that is, versioning-enabled and versioning-suspended buckets).

- **`NoncurrentVersionTransition` action element** – Use this action to specify when Amazon S3 transitions objects to the specified storage class. You can base this transition on a certain number of days since the objects became noncurrent (`<NoncurrentDays>`). In addition to the number of days, you can also specify the number of noncurrent versions (`<NewerNoncurrentVersions>`) to retain (between 1 and 100). This value determines how many newer noncurrent versions must exist before Amazon S3 can transition a given version. Amazon S3 will transition any additional noncurrent versions beyond the specified number to retain. For the transition to occur, both the `<NoncurrentDays>` **and** the `<NewerNoncurrentVersions>` values must be exceeded.

  To specify the number of noncurrent versions to retain, you must also provide a `<Filter>` element. If you don't specify a `<Filter>` element, Amazon S3 generates an `InvalidRequest` error when you specify the number of noncurrent versions to retain.

  For more information about transitioning objects, see Supported transitions. For details about how Amazon S3 calculates the date when you specify the number of days in the `NoncurrentVersionTransition` action, see Lifecycle rules: Based on an object's age.
- **`NoncurrentVersionExpiration` action element** – Use this action to direct Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects can't be recovered. You can base this expiration on a certain number of days since the objects became noncurrent (`<NoncurrentDays>`). In addition to the number of days, you can also specify the number of noncurrent versions (`<NewerNoncurrentVersions>`) to retain (between 1 and 100). This value specifies how many newer noncurrent versions must exist before Amazon S3 can expire a given

version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `<NoncurrentDays>` **and** the `<NewerNoncurrentVersions>` values must be exceeded.

To specify the number of noncurrent versions to retain, you must also provide a `<Filter>` element. If you don't specify a `<Filter>` element, Amazon S3 generates an `InvalidRequest` error when you specify the number of noncurrent versions to retain.

Delayed removal of noncurrent objects can be helpful when you need to correct any accidental deletes or overwrites. For example, you can configure an expiration rule to delete noncurrent versions five days after they become noncurrent. For example, suppose that on 1/1/2014 at 10:30 AM UTC, you create an object called `photo.gif` (version ID 111111). On 1/2/2014 at 11:30 AM UTC, you accidentally delete `photo.gif` (version ID 111111), which creates a delete marker with a new version ID (such as version ID 4857693). You now have five days to recover the original version of `photo.gif` (version ID 111111) before the deletion is permanent. On 1/8/2014 at 00:00 UTC, the Lifecycle rule for expiration runs and permanently deletes `photo.gif` (version ID 111111), five days after it became a noncurrent version.

For details about how Amazon S3 calculates the date when you specify the number of days in an `NoncurrentVersionExpiration` action, see Lifecycle rules: Based on an object's age.

> **Note**
>
> Object expiration lifecycle configurations don't remove incomplete multipart uploads. To remove incomplete multipart uploads, you must use the `AbortIncompleteMultipartUpload` Lifecycle configuration action that's described later in this section.

In addition to the transition and expiration actions, you can use the following Lifecycle configuration actions to direct Amazon S3 to stop incomplete multipart uploads or to remove expired object delete markers:

- **`AbortIncompleteMultipartUpload` action element** – Use this element to set a maximum time (in days) that you want to allow multipart uploads to remain in progress. If the applicable multipart uploads (determined by the key name `prefix` specified in the Lifecycle rule) aren't successfully completed within the predefined time period, Amazon S3 stops the incomplete multipart uploads. For more information, see Aborting a multipart upload.

> **Note**
>
> You can't specify this lifecycle action in a rule that has a filter that uses object tags.

- **`ExpiredObjectDeleteMarker` action element** – In a versioning-enabled bucket, a delete marker with zero noncurrent versions is referred to as an *expired object delete marker*. You can use this lifecycle action to direct Amazon S3 to remove expired object delete markers. For an example, see Removing expired object delete markers in a versioning-enabled bucket.

> **Note**
>
> You can't specify this lifecycle action in a rule that has a filter that uses object tags.

How Amazon S3 calculates how long an object has been noncurrent

In a versioning-enabled bucket, you can have multiple versions of an object. There is always one current version, and zero or more noncurrent versions. Each time you upload an object, the current version is retained as the noncurrent version and the newly added version, the successor, becomes the current version. To determine the number of days an object is noncurrent, Amazon S3 looks at when its successor was created. Amazon S3 uses the number of days since its successor was created as the number of days an object is noncurrent.

> **Restoring previous versions of an object when using S3 Lifecycle configurations**
>
> As explained in Restoring previous versions, you can use either of the following two methods to retrieve previous versions of an object:
>
> - **Method 1 – Copy a noncurrent version of the object into the same bucket.** The copied object becomes the current version of that object, and all object versions are preserved.
> - **Method 2 – Permanently delete the current version of the object.** When you delete the current object version, you, in effect, turn the noncurrent version into the current version of that object.
>
> When you're using S3 Lifecycle configuration rules with versioning-enabled buckets, we recommend as a best practice that you use Method 1.

S3 Lifecycle operates under an eventually consistent model. A current version that you permanently deleted might not disappear until the changes propagate to all of the Amazon S3 systems. (Therefore, Amazon S3 might be temporarily unaware of this deletion.) In the meantime, the lifecycle rule that you configured to expire noncurrent objects might permanently remove noncurrent objects, including the one that you want to restore. So, copying the old version, as recommended in Method 1, is the safer alternative.

Lifecycle actions and bucket versioning state

Lifecycle rules: Based on an object's age

You can specify a time period, in the number of days from the creation (or modification) of the object, when Amazon S3 can take the specified action.

When you specify the number of days in the `Transition` and `Expiration` actions in an S3 Lifecycle configuration, note the following:

- The value that you specify is the number of days since object creation when the action will occur.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the object creation time and rounding up the resulting time to the next day at midnight UTC. For example, if an object was created on 1/15/2014 at 10:30 AM UTC and you specify 3 days in a transition rule, then the transition date of the object would be calculated as 1/19/2014 00:00 UTC.

Note

Amazon S3 maintains only the last modified date for each object. For example, the Amazon S3 console shows the **Last modified** date in the object's **Properties** pane. When you initially create a new object, this date reflects the date that the object is created. If you replace the object, the date changes accordingly. Therefore, the creation date is synonymous with the **Last modified** date.

When specifying the number of days in the `NoncurrentVersionTransition` and `NoncurrentVersionExpiration` actions in a Lifecycle configuration, note the following:

- The value that you specify is the number of days from when the version of the object becomes noncurrent (that is, when the object is overwritten or deleted) that Amazon S3 will perform the action on the specified object or objects.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the time when the new successor version of the object is created and rounding up the resulting time to the next day at midnight UTC. For example, in your bucket, suppose that you have a current version of an object that was created on 1/1/2014 at 10:30 AM UTC. If the new version of the object that replaces the current version is created on 1/15/2014 at 10:30 AM UTC, and you specify 3 days in a transition rule, the transition date of the object is calculated as 1/19/2014 00:00 UTC.

Lifecycle rules: Based on a specific date

When specifying an action in an S3 Lifecycle rule, you can specify a date when you want Amazon S3 to take the action. When the specific date arrives, Amazon S3 applies the action to all qualified objects (based on the filter criteria).

If you specify an S3 Lifecycle action with a date that is in the past, all qualified objects become immediately eligible for that lifecycle action.

Important

The date-based action is not a one-time action. Amazon S3 continues to apply the date-based action even after the date has passed, as long as the rule status is `Enabled`. For example, suppose that you specify a date-based `Expiration` action to delete all objects (assume that no filter is specified in the rule). On the specified date, Amazon S3 expires all the objects in the bucket. Amazon S3 also continues to expire any new objects that you create in the bucket. To stop the lifecycle action, you must either remove the action from the lifecycle rule, disable the rule, or delete the rule from the lifecycle configuration.

The date value must conform to the ISO 8601 format. The time is always midnight UTC.

> **Note**
>
> You can't create date-based Lifecycle rules by using the Amazon S3 console, but you can view, disable, or delete such rules.

Adding filters to Lifecycle rules

Filters are an optional Lifecyle rule element that you can use to specify which objects that the rule applies to.

The following elements can be used to filter objects:

Key prefix

You can filter objects based on a prefix. If you want to apply a lifecycle action to a subset of objects with different prefixes, create separate rules for each action.

Object tags

You can filter objects based on one or more tags. Each tag must match both the key and value exactly, and, if you specify multiple tags each tag key must be unique. A filter with multiple object tags applies to a subset of objects that has all the tags specified. If an object has additional tags specified, the filter will still apply.

> **Note**
>
> If you specify only a `Key` element and no `Value` element, the rule will apply only to objects that match the tag key and that do not have a value specified.

Minimum or maximum object size

You can filter objects based on size. You can specify a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes in the same filter. Object size values are in bytes. Maximum filter size is 50 TB. Amazon S3 applies a default minimum object size to lifecycle configuration. For more information, see Example: Allowing objects smaller than 128 KB to be transitioned.

You can combine different filter elements in which case Amazon S3 uses a logical `AND`.

Filter examples

The following examples show how you can use different filter elements:

- **Specifying a filter by using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (`logs/`). For example, the Lifecycle rule applies to the objects `logs/mylog.txt`, `logs/temp1.txt`, and `logs/test.txt`. The rule does not apply to the object `example.jpg`.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
           <Prefix>logs/</Prefix>
        </Filter>
        transition/expiration actions
         ...
    </Rule>
    ...
</LifecycleConfiguration>
```

> **Note**
>
> If you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:
>
> ```
> sales1999/
>                sales2000/
>                sales2001/
> ```
>
> To include all three prefixes in your rule, specify `sales` as the prefix in your lifecycle rule.

If you want to apply a lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a lifecycle action for objects with the key prefixes `projectA/` and `projectB/`, you specify two rules as follows:

```
<LifecycleConfiguration>
    <Rule>
```

```
        <Filter>
           <Prefix>projectA/</Prefix>
        </Filter>
        transition/expiration actions
         ...
    </Rule>

    <Rule>
        <Filter>
           <Prefix>projectB/</Prefix>
        </Filter>
        transition/expiration actions
         ...
    </Rule>
</LifecycleConfiguration>
```

For more information about object keys, see Naming Amazon S3 objects.

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (*key*) and value (*value*). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
           <Tag>
              <Key>key</Key>
              <Value>value</Value>
           </Tag>
        </Filter>
        transition/expiration actions
        ...
    </Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the <And> element, as shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
    <Rule>
      <Filter>
```

```
          <And>
             <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
             </Tag>
             <Tag>
                <Key>key2</Key>
                <Value>value2</Value>
             </Tag>
              ...
          </And>
      </Filter>
      transition/expiration actions
    </Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a <Key> element and no <Value> element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

> **Note**
>
> When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the <And> element, as follows:

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
          <And>
             <Prefix>key-prefix</Prefix>
             <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
```

```
            </Tag>
            <Tag>
               <Key>key2</Key>
               <Value>value2</Value>
            </Tag>
             ...
          </And>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- **Specifying an empty filter** – You can specify an empty filter, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

- **>Specifying an object size filter** – To filter a rule by object size, you can specify a minimum size (ObjectSizeGreaterThan) or a maximum size (ObjectSizeLessThan), or you can specify a range of object sizes.

  Object size values are in bytes. Maximum filter size is 50 TB. Some storage classes have minimum object size limitations. For more information, see Comparing the Amazon S3 storage classes.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
            <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
        </Filter>
        <Status>Enabled</Status>
```

```
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

> **Note**
>
> The `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024 KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreaterThan` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an <And> element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
            <And>
                <Prefix>key-prefix</Prefix>
                <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
                <ObjectSizeLessThan>64000</ObjectSizeLessThan>
            </And>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

How Amazon S3 handles conflicts in lifecycle configurations

Generally, Amazon S3 Lifecycle optimizes for cost. For example, if two expiration policies overlap, the shorter expiration policy is honored so that data is not stored for longer than expected. Likewise, if two transition policies overlap, S3 Lifecycle transitions your objects to the lower-cost storage class.

In both cases, S3 Lifecycle tries to choose the path that is least expensive for you. An exception to this general rule is with the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is favored by S3 Lifecycle over any storage class, aside from the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

Examples of overlapping filters and conflicting lifecycle actions

You might specify an S3 Lifecycle configuration in which you specify overlapping prefixes, or actions. The following examples show how Amazon S3 resolves potential conflicts.

Example 1: Overlapping prefixes (no conflict)

The following example configuration has two rules that specify overlapping prefixes as follows:

- The first rule specifies an empty filter, indicating all objects in the bucket.
- The second rule specifies a key name prefix (`logs/`), indicating only a subset of objects.

Rule 1 requests Amazon S3 to delete all objects one year after creation. Rule 2 requests Amazon S3 to transition a subset of objects to the S3 Standard-IA storage class 30 days after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
```

```
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>30</Days>
    </Transition>
   </Rule>
</LifecycleConfiguration>
```

Since there is no conflict in this case, Amazon S3 will transition the objects with the `logs/` prefix to the S3 Standard-IA storage class 30 days after creation. When any object reaches one year after creation, it will be deleted.

Example 2: Conflicting lifecycle actions

In this example configuration, there are two rules that direct Amazon S3 to perform two different actions on the same set of objects at the same time in the objects' lifetime:

- Both rules specify the same key name prefix, so both rules apply to the same set of objects.
- Both rules specify the same 365 days after object creation when the rules apply.
- One rule directs Amazon S3 to transition objects to the S3 Standard-IA storage class and another rule wants Amazon S3 to expire the objects at the same time.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
```

```
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>365</Days>
    </Transition>
   </Rule>
</LifecycleConfiguration>
```

In this case, because you want objects to expire (to be removed), there is no point in changing the storage class, so Amazon S3 chooses the expiration action on these objects.

Example 3: Overlapping prefixes resulting in conflicting lifecycle actions

In this example, the configuration has two rules, which specify overlapping prefixes as follows:

- Rule 1 specifies an empty prefix (indicating all objects).
- Rule 2 specifies a key name prefix (`logs/`) that identifies a subset of all objects.

For the subset of objects with the `logs/` key name prefix, S3 Lifecycle actions in both rules apply. One rule directs Amazon S3 to transition objects 10 days after creation, and another rule directs Amazon S3 to transition objects 365 days after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>10</Days>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
```

```
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>365</Days>
    </Transition>
   </Rule>
</LifecycleConfiguration>
```

In this case, Amazon S3 chooses to transition them 10 days after creation.

Example 4: Tag-based filtering and resulting conflicting lifecycle actions

Suppose that you have the following S3 Lifecycle configuration that has two rules, each specifying a tag filter:

- Rule 1 specifies a tag-based filter (`tag1/value1`). This rule directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 365 days after creation.
- Rule 2 specifies a tag-based filter (`tag2/value2`). This rule directs Amazon S3 to expire objects 14 days after creation.

The S3 Lifecycle configuration is shown in following example.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Tag>
         <Key>tag1</Key>
         <Value>value1</Value>
      </Tag>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>GLACIER</StorageClass>
      <Days>365</Days>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Tag>
         <Key>tag2</Key>
         <Value>value2</Value>
```

```
      </Tag>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>14</Days>
    </Expiration>
   </Rule>
</LifecycleConfiguration>
```

If an object has both tags, then Amazon S3 has to decide which rule to follow. In this case, Amazon S3 expires the object 14 days after creation. The object is removed, and therefore the transition action does not apply.

Examples of S3 Lifecycle configurations

This section provides examples of S3 Lifecycle configuration. Each example shows how you can specify the XML in each of the example scenarios.

Topics

- Archiving all objects within one day after creation
- Disabling Lifecycle rules temporarily
- Tiering down the storage class over an object's lifetime
- Specifying multiple rules
- Specifying a lifecycle rule for a versioning-enabled bucket
- Removing expired object delete markers in a versioning-enabled bucket
- Lifecycle configuration to abort multipart uploads
- Expiring noncurrent objects that have no data
- Example: Allowing objects smaller than 128 KB to be transitioned

Archiving all objects within one day after creation

Each S3 Lifecycle rule includes a filter that you can use to identify a subset of objects in your bucket to which the S3 Lifecycle rule applies. The following S3 Lifecycle configurations show examples of how you can specify a filter.

- In this S3 Lifecycle configuration rule, the filter specifies a key prefix (`tax/`). Therefore, the rule applies to objects with the key name prefix `tax/`, such as `tax/doc1.txt` and `tax/doc2.txt`.

  The rule specifies two actions that direct Amazon S3 to do the following:

  - Transition objects to the S3 Glacier Flexible Retrieval storage class 365 days (one year) after creation.
  - Delete objects (the `Expiration` action) 3,650 days (10 years) after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition and Expiration Rule</ID>
    <Filter>
       <Prefix>tax/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>3650</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

  Instead of specifying the object age in terms of days after creation, you can specify a date for each action. However, you can't use both `Date` and `Days` in the same rule.

- If you want the S3 Lifecycle rule to apply to all objects in the bucket, specify an empty prefix. In the following configuration, the rule specifies a `Transition` action that directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 0 days after creation. This rule means that the objects are eligible for archival to S3 Glacier Flexible Retrieval at midnight UTC following creation. For more information about lifecycle constraints, see Constraints and considerations for transitions.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Archive all object same-day upon creation</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
```

```
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

- You can specify zero or one key name prefix and zero or more object tags in a filter. The following example code applies the S3 Lifecycle rule to a subset of objects with the `tax/` key prefix and to objects that have two tags with specific key and value. When you specify more than one filter, you must include the <And> element as shown (Amazon S3 applies a logical AND to combine the specified filter conditions).

```
...
<Filter>
   <And>
      <Prefix>tax/</Prefix>
      <Tag>
         <Key>key1</Key>
         <Value>value1</Value>
      </Tag>
      <Tag>
         <Key>key2</Key>
         <Value>value2</Value>
      </Tag>
    </And>
</Filter>
...
```

- You can filter objects based only on tags. For example, the following S3 Lifecycle rule applies to objects that have the two specified tags (it does not specify any prefix).

```
...
<Filter>
   <And>
      <Tag>
         <Key>key1</Key>
         <Value>value1</Value>
      </Tag>
      <Tag>
         <Key>key2</Key>
```

```
          <Value>value2</Value>
      </Tag>
    </And>
</Filter>
...
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Disabling Lifecycle rules temporarily

You can temporarily disable an S3 Lifecycle rule using the `status` element. This can be useful if you want to test new rules or troubleshoot issues with your configuration, without overwriting your existing rules. The following S3 Lifecycle configuration specifies two rules:

- Rule 1 directs Amazon S3 to transition objects with the `logs/` prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.
- Rule 2 directs Amazon S3 to transition objects with the `documents/` prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.

In the configuration, Rule 1 is enabled and Rule 2 is disabled. Amazon S3 ignores the disabled rule.

```
<LifecycleConfiguration>
```

```
  <Rule>
    <ID>Rule1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule2</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
    <Status>Disabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

Tiering down the storage class over an object's lifetime

In this example, you use S3 Lifecycle configuration to tier down the storage class of objects over their lifetime. Tiering down can help reduce storage costs. For more information about pricing, see Amazon S3 pricing.

The following S3 Lifecycle configuration specifies a rule that applies to objects with the key name prefix `logs/`. The rule specifies the following actions:

- Two transition actions:
  - Transition objects to the S3 Standard-IA storage class 30 days after creation.
  - Transition objects to the S3 Glacier Flexible Retrieval storage class 90 days after creation.
- One expiration action that directs Amazon S3 to delete objects a year after creation.

```
<LifecycleConfiguration>
  <Rule>
```

```
    <ID>example-id</ID>
    <Filter>
       <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>30</Days>
      <StorageClass>STANDARD_IA</StorageClass>
    </Transition>
    <Transition>
      <Days>90</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

Note

You can use one rule to describe all S3 Lifecycle actions if all actions apply to the same set of objects (identified by the filter). Otherwise, you can add multiple rules with each specifying a different filter.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Specifying multiple rules

You can specify multiple rules if you want different S3 Lifecycle actions of different objects. The following S3 Lifecycle configuration has two rules:

- Rule 1 applies to objects with the key name prefix `classA/`. It directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class one year after creation and expire these objects 10 years after creation.
- Rule 2 applies to objects with key name prefix `classB/`. It directs Amazon S3 to transition objects to the S3 Standard-IA storage class 90 days after creation and delete them one year after creation.

```
<LifecycleConfiguration>
    <Rule>
        <ID>ClassADocRule</ID>
        <Filter>
           <Prefix>classA/</Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>365</Days>
           <StorageClass>GLACIER</StorageClass>
        </Transition>
        <Expiration>
             <Days>3650</Days>
        </Expiration>
    </Rule>
    <Rule>
        <ID>ClassBDocRule</ID>
        <Filter>
            <Prefix>classB/</Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>90</Days>
           <StorageClass>STANDARD_IA</StorageClass>
        </Transition>
        <Expiration>
             <Days>365</Days>
        </Expiration>
```

```
    </Rule>
</LifecycleConfiguration>
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Specifying a lifecycle rule for a versioning-enabled bucket

Suppose that you have a versioning-enabled bucket, which means that for each object, you have a current version and zero or more noncurrent versions. (For more information about S3 Versioning, see Retaining multiple versions of objects with S3 Versioning.)

In the following example, you want to maintain one year's worth of history, and retain 5 noncurrent versions. S3 Lifecycle configurations support keeping 1 to 100 versions of any object. Be aware that more than 5 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

To save storage costs, you want to move noncurrent versions to S3 Glacier Flexible Retrieval 30 days after they become noncurrent (assuming that these noncurrent objects are cold data for which you don't need real-time access). In addition, you expect the frequency of access of the current versions to diminish 90 days after creation, so you might choose to move these objects to the S3 Standard-IA storage class.

```
<LifecycleConfiguration>
```

```
    <Rule>
        <ID>sample-rule</ID>
        <Filter>
           <Prefix></Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>90</Days>
           <StorageClass>STANDARD_IA</StorageClass>
        </Transition>
        <NoncurrentVersionTransition>
            <NoncurrentDays>30</NoncurrentDays>
            <StorageClass>GLACIER</StorageClass>
        </NoncurrentVersionTransition>
       <NoncurrentVersionExpiration>
            <NewerNoncurrentVersions>5</NewerNoncurrentVersions>
            <NoncurrentDays>365</NoncurrentDays>
       </NoncurrentVersionExpiration>
    </Rule>
</LifecycleConfiguration>
```

Removing expired object delete markers in a versioning-enabled bucket

A versioning-enabled bucket has one current version and zero or more noncurrent versions for each object. When you delete an object, note the following:

- If you don't specify a version ID in your delete request, Amazon S3 adds a delete marker instead of deleting the object. The current object version becomes noncurrent, and the delete marker becomes the current version.
- If you specify a version ID in your delete request, Amazon S3 deletes the object version permanently (a delete marker isn't created).
- A delete marker with zero noncurrent versions is referred to as an *expired object delete marker*.

This example shows a scenario that can create expired object delete markers in your bucket, and how you can use S3 Lifecycle configuration to direct Amazon S3 to remove the expired object delete markers.

Suppose that you write an S3 Lifecycle configuration that uses the `NoncurrentVersionExpiration` action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions, as shown in the following example. Be

aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

```
<LifecycleConfiguration>
    <Rule>
        ...
        <NoncurrentVersionExpiration>
            <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
            <NoncurrentDays>30</NoncurrentDays>
        </NoncurrentVersionExpiration>
    </Rule>
</LifecycleConfiguration>
```

The `NoncurrentVersionExpiration` action doesn't apply to the current object versions. It removes only the noncurrent versions.

For current object versions, you have the following options to manage their lifetime, depending on whether the current object versions follow a well-defined lifecycle:

- **The current object versions follow a well-defined lifecycle.**

  In this case, you can use an S3 Lifecycle configuration with the `Expiration` action to direct Amazon S3 to remove the current versions, as shown in the following example.

  ```
  <LifecycleConfiguration>
      <Rule>
          ...
          <Expiration>
             <Days>60</Days>
          </Expiration>
          <NoncurrentVersionExpiration>
              <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
              <NoncurrentDays>30</NoncurrentDays>
          </NoncurrentVersionExpiration>
      </Rule>
  </LifecycleConfiguration>
  ```

  In this example, Amazon S3 removes current versions 60 days after they're created by adding a delete marker for each of the current object versions. This process makes the current version

noncurrent, and the delete marker becomes the current version. For more information, see Retaining multiple versions of objects with S3 Versioning.

> **Note**
>
> You can't specify both a `Days` and an `ExpiredObjectDeleteMarker` tag on the same rule. When you specify the `Days` tag, Amazon S3 automatically performs `ExpiredObjectDeleteMarker` cleanup when the delete markers are old enough to satisfy the age criteria. To clean up delete markers as soon as they become the only version, create a separate rule with only the `ExpiredObjectDeleteMarker` tag.

The `NoncurrentVersionExpiration` action in the same S3 Lifecycle configuration removes noncurrent objects 30 days after they become noncurrent. Thus, in this example, all object versions are permanently removed 90 days after object creation. Be aware that in this example, more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

Although expired object delete markers are created during this process, Amazon S3 detects and removes the expired object delete markers for you.

- **The current object versions don't have a well-defined lifecycle.**

  In this case, you might remove the objects manually when you don't need them, creating a delete marker with one or more noncurrent versions. If your S3 Lifecycle configuration with the `NoncurrentVersionExpiration` action removes all the noncurrent versions, you now have expired object delete markers.

  Specifically for this scenario, S3 Lifecycle configuration provides an `Expiration` action that you can use to remove the expired object delete markers.

```
<LifecycleConfiguration>
    <Rule>
       <ID>Rule 1</ID>
        <Filter>
          <Prefix>logs/</Prefix>
        </Filter>
```

```
        <Status>Enabled</Status>
        <Expiration>
           <ExpiredObjectDeleteMarker>true</ExpiredObjectDeleteMarker>
        </Expiration>
        <NoncurrentVersionExpiration>
            <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
            <NoncurrentDays>30</NoncurrentDays>
        </NoncurrentVersionExpiration>
    </Rule>
</LifecycleConfiguration>
```

By setting the `ExpiredObjectDeleteMarker` element to `true` in the `Expiration` action, you direct Amazon S3 to remove the expired object delete markers.

> **Note**
>
> When you use the `ExpiredObjectDeleteMarker` S3 Lifecycle action, the rule cannot specify a tag-based filter.

Lifecycle configuration to abort multipart uploads

You can use the Amazon S3 multipart upload REST API operations to upload large objects in parts. For more information about multipart uploads, see Uploading and copying objects using multipart upload in Amazon S3.

By using an S3 Lifecycle configuration, you can direct Amazon S3 to stop incomplete multipart uploads (identified by the key name prefix specified in the rule) if they aren't completed within a specified number of days after initiation. When Amazon S3 aborts a multipart upload, it deletes all the parts associated with the multipart upload. This process helps control your storage costs by ensuring that you don't have incomplete multipart uploads with parts that are stored in Amazon S3.

> **Note**
>
> When you use the `AbortIncompleteMultipartUpload` S3 Lifecycle action, the rule cannot specify a tag-based filter.

The following is an example S3 Lifecycle configuration that specifies a rule with the `AbortIncompleteMultipartUpload` action. This action directs Amazon S3 to stop incomplete multipart uploads seven days after initiation.

```
<LifecycleConfiguration>
    <Rule>
        <ID>sample-rule</ID>
        <Filter>
           <Prefix>SomeKeyPrefix/</Prefix>
        </Filter>
        <Status>rule-status</Status>
        <AbortIncompleteMultipartUpload>
          <DaysAfterInitiation>7</DaysAfterInitiation>
        </AbortIncompleteMultipartUpload>
    </Rule>
</LifecycleConfiguration>
```

Expiring noncurrent objects that have no data

You can create rules that transition objects based only on their size. You can specify a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes in bytes. When using more than one filter, such as a prefix and size rule, you must wrap the filters in an <And> element.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition with a prefix and based on size</ID>
    <Filter>
       <And>
          <Prefix>tax/</Prefix>
          <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
       </And>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

If you're specifying a range by using both the `ObjectSizeGreaterThan` and `ObjectSizeLessThan` elements, the maximum object size must be larger than the minimum object size. When using more than one filter, you must wrap the filters in an <And> element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes. When you're specifying a range, the `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For more information, see the section called “Filter element”.

```
<LifecycleConfiguration>
    <Rule>
        ...
          <And>
             <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
             <ObjectSizeLessThan>64000</ObjectSizeLessThan>
          </And>
    </Rule>
</LifecycleConfiguration>
```

You can also create rules to specifically expire noncurrent objects that have no data, including noncurrent delete marker objects created in a versioning-enabled bucket. The following example uses the `NoncurrentVersionExpiration` action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions. This example also uses the `ObjectSizeLessThan` element to filter only objects with no data.

Be aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Expire noncurrent with size less than 1 byte</ID>
    <Filter>
       <ObjectSizeLessThan>1</ObjectSizeLessThan>
    </Filter>
    <Status>Enabled</Status>
    <NoncurrentVersionExpiration>
       <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
       <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
```

```
</LifecycleConfiguration>
```

Example: Allowing objects smaller than 128 KB to be transitioned

Amazon S3 applies a default behavior to your Lifecycle configuration that prevents objects smaller than 128 KB from being transitioned to any storage class. You can allow smaller objects to transition by adding a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`) filter that specifies a smaller size to the configuration. The following example allows any object smaller than 128 KB to transition to the S3 Glacier Instant Retrieval storage class:

```
<LifecycleConfiguration>
  <Rule>
    <ID>Allow small object transitions</ID>
    <Filter>
          <ObjectSizeGreaterThan>1</ObjectSizeGreaterThan>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER_IR</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

Note

In September 2024, Amazon S3 updated the default transition behavior for small objects, as follows:

- **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.
- **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.

Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case requires,

you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-object-size-minimum-default` header in a PutBucketLifecycleConfiguration request.

The following example shows how to use the `x-amz-transition-object-size-minimum-default` header in a PutBucketLifecycleConfiguration request to apply the `varies_by_storage_class` default transition behavior to an S3 Lifecycle configuration. This behavior allows object smaller than 128 KB to transition to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. By default, all other storage classes will prevent transitions smaller than 128 KB. You can still use custom filters to change the minimum transition size for any storage class. Custom filters always take precedence over the default transition behavior:

```
HTTP/1.1 200
x-amz-transition-object-size-minimum-default: varies_by_storage_class
<?xml version="1.0" encoding="UTF-8"?>
...
```

Troubleshooting Amazon S3 Lifecycle issues

The following information can help you troubleshoot common issues with Amazon S3 Lifecycle rules.

Topics

- I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.
- How do I monitor the actions taken by my lifecycle rules?
- My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.
- How do I empty my S3 bucket by using lifecycle rules?
- My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.
- I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.
- Can I recover S3 objects that are expired by S3 Lifecycle rules?
- Why are my expiration and transition lifecycle actions not occurring?

- How can I exclude a prefix from my lifecycle rule?
- How can I include multiple prefixes in my lifecycle rule?

I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.

S3 Lifecycle object transitions and object expirations are asynchronous operations. Therefore, there might be a delay between the time that the objects are eligible for expiration or transition and the time that they are actually transitioned or expired. Changes in billing are applied as soon as the lifecycle rule is satisfied, even if the action isn't complete. The exception to this behavior is if you have a lifecycle rule set to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For transitions to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive, billing at the destination storage class rate, the per-object storage overhead (40 KB), and the minimum storage duration timer all begin when the lifecycle rule is satisfied, even though the physical transition occurs asynchronously. For more information about changes in billing, see Setting lifecycle configuration on a bucket.

> **Note**
>
> Amazon S3 doesn't transition objects that are smaller than 128 KB from the S3 Standard or S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage class.

How do I monitor the actions taken by my lifecycle rules?

To monitor actions taken by lifecycle rules, you can use the following features:

- **S3 Event Notifications** – You can set up S3 Event Notifications so that you're notified of any S3 Lifecycle expiration or transition events.
- **S3 server access logs** – You can enable server access logs for your S3 buckets to capture S3 Lifecycle actions, such as object transitions to another storage class or object expirations. For more information, see Lifecycle and logging.
- **S3 Metadata journal tables** – A journal table records object-level changes in your bucket in near real time, including expirations and transitions made by S3 Lifecycle (the `requester` is `s3.amazonaws.com`). You can query the table to see which objects S3 Lifecycle has removed

and when. The journal table records changes only after you create the metadata configuration. For more information, see S3 Metadata journal tables schema.

- **S3 Inventory** – An S3 Inventory report that includes the Lifecycle Expiration Date field shows the expiration date that your lifecycle rules set for each object. Use it to confirm that your rules apply to the objects you expect, and to find objects that are past their expiration date but haven't been removed yet. For more information, see Cataloging and analyzing your data with S3 Inventory.

Because S3 Lifecycle runs asynchronously, use these features to track progress for your bucket. Event notifications, server access logs, and journal tables show actions as S3 Lifecycle completes them. S3 Inventory shows what remains. For more information, see Transition or expiration delay.

To view the changes in your storage caused by lifecycle actions on a daily basis, we recommend using S3 Storage Lens dashboards instead of using Amazon CloudWatch metrics. In your Storage Lens dashboard, you can view the following metrics, which monitor the object count or size:

- **Current version bytes**
- **Current version object count**
- **Noncurrent version bytes**
- **Noncurrent version object count**
- **Delete marker object count**
- **Delete marker storage bytes**
- **Incomplete multipart upload bytes**
- **Incomplete multipart upload object count**

My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.

In a versioning-enabled bucket, when an object is expired, the object isn't completely deleted from the bucket. Instead, a delete marker is created as the newest version of the object. Delete markers are still counted as objects. Therefore, if a lifecycle rule is created to expire only the current versions, then the object count in the S3 bucket actually increases instead of going down.

For example, let's say an S3 bucket is versioning-enabled with 100 objects, and a lifecycle rule is set to expire current versions of the object after 7 days. After the seventh day, the object count

increases to 200 because 100 delete markers are created in addition to the 100 original objects, which are now the noncurrent versions. For more information about S3 Lifecycle configuration rule actions for versioning-enabled buckets, see Setting lifecycle configuration on a bucket.

To permanently remove objects, add an additional lifecycle configuration to delete the previous versions of the objects, expired delete markers, and incomplete multipart uploads. For instructions on how to create new lifecycle rules, see Setting lifecycle configuration on a bucket.

Note

- Amazon S3 rounds the transition or expiration date of an object to midnight UTC the next day.

  When evaluating objects for lifecycle actions, Amazon S3 uses the object creation time in UTC. For example, consider a nonversioned bucket with a lifecycle rule that's configured to expire objects after one day. Suppose that an object was created on January 1 at 17:05 Pacific Daylight Time (PDT), which corresponds to January 2 at 00:05 UTC. The object becomes one day old at 00:05 UTC on January 3, which makes it eligible for expiration when S3 Lifecycle evaluates objects at 00:00 UTC on January 4.

  Because Amazon S3 lifecycle actions occur asynchronously, there might be some delay between the date specified in the lifecycle rule and the actual physical transition of the object. For more information, see Transition or expiration delay.

  For more information, see Lifecycle rules: Based on an object's age.
- For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

How do I empty my S3 bucket by using lifecycle rules?

S3 Lifecycle rules are an effective tool to empty an S3 bucket with millions of objects. To delete a large number of objects from your S3 bucket, make sure to use these two pairs of lifecycle rules:

- **Expire current versions of objects** and **Permanently delete previous versions of objects**
- **Delete expired delete markers** and **Delete incomplete multipart uploads**

For steps on how to create a lifecycle configuration rule, see Setting lifecycle configuration on a bucket.

> **Note**
>
> For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.

There are several reasons that your bill might increase after transitioning objects to a lower-cost storage class:

- S3 Glacier overhead charges for small objects

  For each object that is transitioned to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a total overhead of 40 KB is associated with this storage update. As part of the 40 KB overhead, 8 KB is used to store metadata and the name of the object. This 8 KB is charged according to S3 Standard rates. The remaining 32 KB is used for indexing and related metadata. This 32 KB is charged according to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive pricing.

  Therefore, if you're storing many smaller sized objects, we don't recommend using lifecycle transitions. Instead, to reduce any overhead charges, consider aggregating many smaller objects into a smaller number of large objects before storing them in Amazon S3. For more information about cost considerations, see Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival).
- Minimum storage charges

  Some S3 storage classes have minimum storage-duration requirements. Objects that are deleted, overwritten, or transitioned from those classes before the minimum duration is satisfied are charged a prorated early transition or deletion fee. These minimum storage-duration requirements are as follows:
  - S3 Standard-IA and S3 One Zone-IA – 30 days
  - S3 Glacier Flexible Retrieval and S3 Glacier Instant Retrieval – 90 days
  - S3 Glacier Deep Archive – 180 days

For more information about these requirements, see the *Constraints* section of Transitioning objects using S3 Lifecycle. For general S3 pricing information, see Amazon S3 pricing and the AWS Pricing Calculator.

- Lifecycle transition costs

  Each time an object is transitioned to a different storage class by a lifecycle rule, Amazon S3 counts that transition as one transition request. The costs for these transition requests are in addition to the costs of these storage classes. If you plan to transition a large number of objects, consider the request costs when transitioning to a lower tier. For more information, see Amazon S3 pricing.

I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.

`Deny` statements in a bucket policy don't prevent the expiration of the objects defined in a lifecycle rule. Lifecycle actions (such as transitions or expirations) don't use the S3 `DeleteObject` operation. Instead, S3 Lifecycle actions are performed by using internal S3 endpoints. (For more information, see Lifecycle and logging.)

To prevent your lifecycle rule from taking any action, you must edit, delete, or disable the rule.

Can I recover S3 objects that are expired by S3 Lifecycle rules?

The only way to recover objects that are expired by S3 Lifecycle is through versioning, which must be in place before the objects become eligible for expiration. You cannot undo the expiration operations that are performed by lifecycle rules. If objects are permanently deleted by the S3 Lifecycle rules that are in place, you cannot recover these objects. To enable versioning on a bucket, see the section called "Retaining multiple versions of objects".

If you have applied versioning to the bucket and the noncurrent versions of the objects are still intact, you can restore previous versions of the expired objects. For more information about the behavior of S3 Lifecycle rule actions and versioning states, see the *Lifecycle actions and bucket versioning state* table in Elements to describe lifecycle actions.

> **Note**
>
> If the S3 bucket is protected by AWS Backup or S3 Replication, you might also be able to use these features to recover your expired objects.

Why are my expiration and transition lifecycle actions not occurring?

For a versioning-enabled or versioning-suspended bucket, the following considerations guide how Amazon S3 handles the Expiration action:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- Amazon S3 doesn't take any action on noncurrent versions of objects that have S3 Object Lock applied.
- For objects with a `PENDING` or `FAILED` replication status, Amazon S3 doesn't take any action on current or noncurrent versions of objects.

Lifecycle storage class transitions have the following constraints:

- By default, objects smaller than 128 KB won't transition to any storage class.
- For versioning enabled or versioning suspended buckets, objects with a `PENDING` or `FAILED` replication status can't be transitioned.

How can I exclude a prefix from my lifecycle rule?

S3 Lifecycle doesn't support excluding prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see the section called “Archiving all objects within one day after creation”.

How can I include multiple prefixes in my lifecycle rule?

S3 Lifecycle doesn't support including multiple prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see the section called “Archiving all objects within one day after creation”.

However, if you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:

```
sales1999/
sales2000/
sales2001/
```

To include all three prefixes in your rule, specify `<Prefix>sales</Prefix>` in your lifecycle rule.

Logging and monitoring in Amazon S3

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. We recommend collecting monitoring data from all of the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs. Before you start monitoring Amazon S3, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

For more information about logging and monitoring in Amazon S3, see the following topics.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon S3 resources and responding to potential incidents.

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring metrics with Amazon CloudWatch.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

Amazon GuardDuty

Amazon GuardDuty is a threat detection service that continuously monitors your accounts, containers, workloads, and the data within your AWS environment to identify potential threats or security risks to your S3 buckets. GuardDuty also provides rich context about the threats that it detects. GuardDuty monitors AWS CloudTrail management logs for threats and surfaces security relevant information. For example, GuardDuty will include factors of an API request, such as the user that made the request, the location the request was made from, and the specific API requested, that could be unusual in your environment. GuardDuty S3 Protection monitors the S3 data events collected by CloudTrail and identifies potentially anomalous and malicious behavior in all the S3 buckets in your environment.

Amazon S3 Access Logs

Server access logs provide detailed records about requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. You can deliver logs to Amazon CloudWatch Logs for structured querying and cross-account aggregation, or to an Amazon S3 general purpose bucket in text format at no charge. For more information, see Logging requests with server access logging.

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon S3-related checks:

- Logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that don't have versioning enabled, or have versioning suspended.

For more information, see AWS Trusted Advisor in the *Support User Guide*.

Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads.

S3 Storage Lens aggregates your metrics and displays the information in the Account snapshot section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. For more information, see Understanding Amazon S3 Storage Lens.

Amazon S3 Inventory

Amazon S3 Inventory generates a list of objects and metadata that you can use to query and manage your objects. You can use this inventory report to generate granular data such as object size, last modified date, encryption status and other fields. Those reports are available daily or weekly to automatically give the latest list.

For example, you can use Amazon S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also use Amazon S3 Inventory to simplify and speed up business workflows and big data jobs, which provides a scheduled alternative to the Amazon S3 synchronous `List` API operations. Amazon S3 Inventory doesn't use the `List` API operations to audit your objects and does not affect the request rate of your bucket. For more information, see Cataloging and analyzing your data with S3 Inventory.

Amazon S3 Event Notifications

With the Amazon S3 Event Notifications feature, you receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that identifies the events that you want Amazon S3 to publish. For more information, see Amazon S3 Event Notifications.

Amazon S3 and AWS X-Ray

AWS X-Ray integrates with Amazon S3 to trace upstream requests to update your application's S3 buckets. If a service traces requests by using the X-Ray SDK, Amazon S3 can send the tracing headers to downstream event subscribers such as Λ, Amazon SQS, and Amazon SNS. X-Ray enables trace messages for Amazon S3 event notifications. You can use the X-Ray trace map to view the connections between Amazon S3 and other services that your application uses. For more information, see Amazon S3 and X-Ray.

The following security best practices also address logging and monitoring:

- Identify and audit all your Amazon S3 buckets
- Implement monitoring using Amazon Web Services monitoring tools
- Enable AWS Config
- Enable Amazon S3 server access logging
- Use CloudTrail
- Monitor Amazon Web Services security advisories

Topics

- Monitoring tools
- Logging options for Amazon S3
- Logging Amazon S3 API calls using AWS CloudTrail
- Logging requests with server access logging
- Monitoring metrics with Amazon CloudWatch
- Amazon S3 Event Notifications
- Monitoring your storage activity and usage with Amazon S3 Storage Lens
- Cataloging and analyzing your data with S3 Inventory

Monitoring tools

AWS provides various tools that you can use to monitor Amazon S3. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon S3 and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods. For more information, see Monitoring metrics with Amazon CloudWatch.
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

Manual monitoring tools

Another important part of monitoring Amazon S3 involves manually monitoring those items that the CloudWatch alarms don't cover. The Amazon S3, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. You might want to enable *server access logging*, which tracks requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. For more information, see Logging requests with server access logging.

- The Amazon S3 dashboard shows the following:
  - Your buckets and the objects and properties they contain
- The CloudWatch home page shows the following:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

  In addition, you can use CloudWatch to do the following:
  - Create customized dashboards to monitor the services you care about.

- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.

- AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see AWS Trusted Advisor.

  Trusted Advisor has these checks that relate to Amazon S3:

  - Checks of the logging configuration of Amazon S3 buckets.
  - Security checks for Amazon S3 buckets that have open access permissions.
  - Fault tolerance checks for Amazon S3 buckets that do not have versioning enabled, or have versioning suspended.

Logging options for Amazon S3

You can record the actions that are taken by users, roles, or AWS services on Amazon S3 resources and maintain log records for auditing and compliance purposes. To do this, you can use server-access logging, AWS CloudTrail logging, or a combination of both. We recommend that you use CloudTrail for logging bucket-level and object-level actions for your Amazon S3 resources. For more information about each option, see the following sections:

- Logging requests with server access logging
- Logging Amazon S3 API calls using AWS CloudTrail

Amazon S3 offers two delivery paths for server access logs: direct delivery to an Amazon S3 general purpose bucket and delivery to Amazon CloudWatch Logs. Some capabilities in the following table apply to server access logs only through the Amazon CloudWatch Logs delivery path, as noted.

The following table lists the key properties of CloudTrail logs and Amazon S3 server-access logs. To make sure that CloudTrail meets your security requirements, review the table and notes.

Log properties	AWS CloudTrail	Amazon S3 server logs
Can be forwarded to other systems (Amazon CloudWatch Logs, Amazon CloudWatch Events)	Yes	Yes
Deliver logs to more than one destination (for example, send the same logs to two different buckets)	Yes	Yes[3]
Turn on logs for a subset of objects (prefix)	Yes	No
Cross-account log delivery (target and source bucket owned by different accounts)	Yes	Yes[3]
Integrity validation of log file by using digital signature or hashing	Yes	No
Default or choice of encryption for log files	Yes	Yes[3]
Object operations (by using Amazon S3 APIs)	Yes	Yes
Bucket operations (by using Amazon S3 APIs)	Yes	Yes
Searchable UI for logs	Yes	Yes[3]
Fields for Object Lock parameters, Amazon S3 Select properties for log records	Yes	No

Log properties	AWS CloudTrail	Amazon S3 server logs
Fields for `Object Size`, `Total Time`, `Turn-Around Time`, and `HTTP Referer` for log records	Yes	Yes
Lifecycle transitions, expirations, restores	No	Yes
Logging of keys in a batch delete operation	Yes	Yes
Authentication failures[1]	No	Yes
Accounts where logs get delivered	Bucket owner[2], and requester	Bucket owner, and other accounts with Amazon CloudWatch Logs delivery
Performance and Cost	**AWS CloudTrail**	**Amazon S3 Server Logs**
Price	Management events (first delivery) are free; data events incur a fee, in addition to storage of logs	No cost for Amazon S3 bucket delivery in addition to storage of logs; CloudWatch vended logs rates for Amazon CloudWatch Logs delivery[3].
Speed of log delivery	Data events every 5 minutes; management events every 15 minutes	Within a few hours
Log format	JSON	Space-delimited text records for delivery to an Amazon S3 bucket. Structured JSON for delivery to Amazon CloudWatch Logs[3].

Notes

1. CloudTrail does not deliver logs for requests that fail authentication (in which the provided credentials are not valid) or that fail due to redirection (error code `301 Moved Permanently`). However, it does include logs for requests in which authorization fails (`AccessDenied`) and requests that are made by anonymous users.
2. The S3 bucket owner receives CloudTrail logs when the account does not have full access to the object in the request. For more information, see Amazon S3 object-level actions in cross-account scenarios.
3. In addition to direct delivery to an Amazon S3 bucket, you can deliver Amazon S3 server access logs to Amazon CloudWatch Logs. With this delivery path, you gain additional capabilities, including forwarding to other destinations, delivery to multiple destinations, cross-account and cross-Region aggregation, AWS KMS encryption, and interactive querying with CloudWatch Logs Insights. You can also deliver these logs to Amazon S3 Tables in Apache Iceberg format for SQL analytics. For more information, see Logging requests with server access logging.
4. S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Logging Amazon S3 API calls using AWS CloudTrail

AWS CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. The calls captured include calls from the Amazon S3 console and code calls to the Amazon S3 API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a trail for your AWS account and Creating a trail for an organization in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can store your log files in your bucket for as long as you want, but you can also define Amazon S3 Lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted by using Amazon S3 server-side encryption (SSE).

Using CloudTrail logs with Amazon S3 server access logs and CloudWatch Logs

AWS CloudTrail logs provide a record of actions taken by a user, role, or an AWS service in Amazon S3, while Amazon S3 server access logs provide detailed records for the requests that are made to an S3 bucket. For more information about how the different logs work, and their properties, performance, and costs, see the section called “Logging options”.

You can use AWS CloudTrail logs together with server access logs for Amazon S3. CloudTrail logs provide you with detailed API tracking for Amazon S3 bucket-level and object-level operations. Server access logs for Amazon S3 provide you with visibility into object-level operations on your data in Amazon S3. For more information about server access logs, see Logging requests with server access logging.

You can also use CloudTrail logs together with Amazon CloudWatch for Amazon S3. CloudTrail integration with CloudWatch Logs delivers S3 bucket-level API activity captured by CloudTrail to a CloudWatch log stream in the CloudWatch log group that you specify. You can create CloudWatch alarms for monitoring specific API activity and receive email notifications when the specific API activity occurs. For more information about CloudWatch alarms for monitoring specific API activity, see the AWS CloudTrail User Guide. For more information about using CloudWatch with Amazon S3, see Monitoring metrics with Amazon CloudWatch.

> **Note**
>
> S3 does not support delivery of CloudTrail logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

CloudTrail tracking with Amazon S3 SOAP API calls

CloudTrail tracks Amazon S3 SOAP API calls. Amazon S3 SOAP support over HTTP is deprecated, but it is still available over HTTPS. For more information about Amazon S3 SOAP support, see Appendix: SOAP API in the *Amazon S3 API Reference*.

Important

Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

The following table shows Amazon S3 SOAP actions tracked by CloudTrail logging.

SOAP API name	API event name used in CloudTrail log
ListAllMyBuckets	`ListBuckets`
CreateBucket	`CreateBucket`
DeleteBucket	`DeleteBucket`
GetBucketAccessControlPolicy	`GetBucketAcl`
SetBucketAccessControlPolicy	`PutBucketAcl`
GetBucketLoggingStatus	`GetBucketLogging`
SetBucketLoggingStatus	`PutBucketLogging`

For more information about CloudTrail and Amazon S3, see the following topics:

Topics

- Amazon S3 CloudTrail events
- CloudTrail log file entries for Amazon S3 and S3 on Outposts
- Enabling CloudTrail event logging for S3 buckets and objects
- Identifying Amazon S3 requests using CloudTrail

Amazon S3 CloudTrail events

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

This section provides information about the events that S3 logs to CloudTrail.

Amazon S3 data events in CloudTrail

Data events provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can log data events for the Amazon S3 resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see Logging data events with the AWS Management Console and Logging data events with the AWS Command Line Interface in the *AWS CloudTrail User Guide*.

The following table lists the Amazon S3 resource types for which you can log data events. The **Data event type (console)** column shows the value to choose from the **Data event type** list on the CloudTrail console. The **resources.type value** column shows the `resources.type` value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The **Data APIs logged to CloudTrail** column shows the API calls logged to CloudTrail for the resource type.

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3	`AWS::S3::Object`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • DeleteObjects • GetObject • GetObjectAcl • GetObjectAttributes • GetObjectLegalHold • GetObjectRetention • GetObjectTagging • GetObjectTorrent • HeadObject • HeadBucket • ListObjectVersions • ListObjects • ListParts • PutObject • PutObjectAcl • PutObjectLegalHold • PutObjectRetention • PutObjectTagging • PutObjectAnnotation • GetObjectAnnotation • ListObjectAnnotations • DeleteObjectAnnotation

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
		• RestoreObject • SelectObjectContent • UpdateObjectEncryption • UploadPart • UploadPartCopy
S3 Express One Zone	`AWS::S3Express::Object`	• AbortMultipartUpload • CompleteMultipartUpload • CreateSession • CopyObject • CreateMultipartUpload • DeleteObject • DeleteObjects • GetObject • GetObjectAttributes • HeadBucket • HeadObject • ListObjectsV2 • ListParts • PutObject • UploadPart • UploadPartCopy

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Access Point	`AWS::S3::Access Point`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetObject • GetObjectAcl • GetObjectAttributes • GetObjectLegalHold • GetObjectRetention • GetObjectTagging • HeadBucket • HeadObject • ListObjects • ListObjectsV2 • ListObjectVersions • ListParts • Presign • PutObject • PutObjectLegalHold • PutObjectRetention • PutObjectAcl • PutObjectTagging • RestoreObject • UploadPart

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
		• UploadPartCopy (same-region copies only)
S3 Object Lambda	`AWS::S3ObjectLambda::AccessPoint`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetObject • GetObjectAcl • GetObjectLegalHold • GetObjectRetention • GetObjectTagging • HeadObject • ListObjects • ListObjectVersions • ListParts • PutObject • PutObjectLegalHold • PutObjectRetention • PutObjectAcl • PutObjectTagging • RestoreObject • UploadPart • WriteGetObjectResponse

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Outposts	`AWS::S3Outposts::Object`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetObject • GetObjectTagging • HeadObject • ListObjects • ListObjectsV2 • ListParts • PutObject • PutObjectTagging • UploadPart • UploadPartCopy

You can configure advanced event selectors to filter on the `eventName`, `readOnly`, and `resources.ARN` fields to log only those events that are important to you. For more information about these fields, see AdvancedFieldSelector in the *AWS CloudTrail API Reference*.

Amazon S3 management events in CloudTrail

Amazon S3 logs all control plane operations as management events. For more information about S3 API operations, see the Amazon S3 API Reference.

How CloudTrail captures requests made to Amazon S3

By default, CloudTrail logs S3 bucket-level API calls that were made in the last 90 days, but not log requests made to objects. Bucket-level calls include events such as `CreateBucket`,

`DeleteBucket`, `PutBucketLifecycle`, `PutBucketPolicy`, and so on. You can see bucket-level events on the CloudTrail console. However, you can't view data events (Amazon S3 object-level calls) there—you must parse or query CloudTrail logs for them.

If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see AWS CLI examples for filtering data events in the *AWS CloudTrail User Guide.*

The `InitiateReplication` event includes `objectAnnotationCount` in the `additionalEventData` field. This value indicates the number of annotations on the source object at the time replication was initiated.

When you call `PutObjectRetention`, the CloudTrail data event is recorded with the `eventName` `PutObjectLockRetention`, and includes `objectRetentionInfo` in `additionalEventData`. This field contains the resulting retention mode, retain-until-date, event hold status, and event hold duration.

Amazon S3 account-level actions tracked by CloudTrail logging

CloudTrail logs account-level actions. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

The tables in this section list the Amazon S3 account-level actions that are supported for logging by CloudTrail.

Amazon S3 account-level API actions tracked by CloudTrail logging appear as the following event names. The CloudTrail event names differ from the API action name. For example, DeletePublicAccessBlock is DeleteAccountPublicAccessBlock.

- DeleteAccountPublicAccessBlock
- GetAccountPublicAccessBlock
- PutAccountPublicAccessBlock

Amazon S3 bucket-level actions that are tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for general purpose buckets. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

This section lists the Amazon S3 bucket-level actions that are supported for logging by CloudTrail.

Amazon S3 bucket-level API actions tracked by CloudTrail logging appear as the following event names. In some cases, the CloudTrail event name differs from the API action name. For example, `PutBucketLifecycleConfiguration` is `PutBucketLifecycle`.

- CreateBucket
- CreateBucketMetadataConfiguration (V2 API operation)
- CreateBucketMetadataTableConfiguration (V1 API operation)
- DeleteBucket
- DeleteBucketAnalyticsConfiguration
- DeleteBucketCors
- DeleteBucketEncryption
- DeleteBucketIntelligentTieringConfiguration
- DeleteBucketInventoryConfiguration
- DeleteBucketLifecycle
- DeleteBucketMetadataConfiguration (V2 API operation)
- DeleteBucketMetadataTableConfiguration (V1 API operation)
- DeleteBucketMetricsConfiguration
- DeleteBucketOwnershipControls
- DeleteBucketPolicy
- DeleteBucketPublicAccessBlock
- DeleteBucketReplication
- DeleteBucketTagging
- GetAccelerateConfiguration
- GetBucketAcl
- GetBucketAnalyticsConfiguration
- GetBucketCors

- GetBucketEncryption
- GetBucketIntelligentTieringConfiguration
- GetBucketInventoryConfiguration
- GetBucketLifecycle
- GetBucketLocation
- GetBucketLogging
- GetBucketMetadataConfiguration (V2 API operation)
- GetBucketMetadataTableConfiguration (V1 API operation)
- GetBucketMetricsConfiguration
- GetBucketNotification
- GetBucketObjectLockConfiguration
- GetBucketOwnershipControls
- GetBucketPolicy
- GetBucketPolicyStatus
- GetBucketPublicAccessBlock
- GetBucketReplication
- GetBucketRequestPayment
- GetBucketTagging
- GetBucketVersioning
- GetBucketWebsite
- HeadBucket
- ListBuckets
- PutAccelerateConfiguration
- PutBucketAcl
- PutBucketAnalyticsConfiguration
- PutBucketCors
- PutBucketEncryption
- PutBucketIntelligentTieringConfiguration
- PutBucketInventoryConfiguration
- PutBucketLifecycle

- PutBucketLogging
- PutBucketMetricsConfiguration
- PutBucketNotification
- PutBucketObjectLockConfiguration
- PutBucketOwnershipControls
- PutBucketPolicy
- PutBucketPublicAccessBlock
- PutBucketReplication
- PutBucketRequestPayment
- PutBucketTagging
- PutBucketVersioning
- PutBucketWebsite
- UpdateBucketMetadataJournalTableConfiguration
- UpdateBucketMetadataInventoryTableConfiguration
- UpdateBucketMetadataAnnotationTableConfiguration

In addition to these API operations, you can also use the OPTIONS object object-level action. This action is treated like a bucket-level action in CloudTrail logging because the action checks the CORS configuration of a bucket.

> **Note**
>
> The HeadBucket API is supported as an Amazon S3 data event in CloudTrail.

Amazon S3 Express One Zone bucket-level (Regional API endpoint) actions tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The `eventsource` for CloudTrail management events for S3 Express One Zone is `s3express.amazonaws.com`.

These following Regional endpoint API operations are logged to CloudTrail.

- CreateBucket

- DeleteBucket
- DeleteBucketPolicy
- GetBucketPolicy
- PutBucketPolicy
- ListDirectoryBuckets
- PutBucketEncryption
- GetBucketEncryption
- DeleteBucketEncryption

For more information, see Logging with AWS CloudTrail for S3 Express One Zone

Amazon S3 object-level actions in cross-account scenarios

The following are special use cases involving the object-level API calls in cross-account scenarios and how CloudTrail logs are reported. CloudTrail delivers logs to the requester (the account that made the API call), except in some access denied cases where log entries are redacted or omitted. When setting up cross-account access, consider the examples in this section.

> **Note**
>
> The examples assume that CloudTrail logs are appropriately configured.

Example 1: CloudTrail delivers logs to the bucket owner

CloudTrail delivers logs to the bucket owner even if the bucket owner does not have permissions for the same object API operation. Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) tries to access an object in that bucket.
- Account C owns the object. Account C might or might not be the same account as Account A.

> **Note**
>
> CloudTrail always delivers object-level API logs to the requester (Account B). In addition, CloudTrail also delivers the same logs to the bucket owner (Account A) even when the

bucket owner does not own the object (Account C) or have permissions for those same API operations on that object.

Example 2: CloudTrail does not proliferate email addresses that are used in setting object ACLs

Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) sends a request to set an object ACL grant by using an email address. For more information about ACLs, see Access control list (ACL) overview.

The requester gets the logs along with the email information. However, the bucket owner—if they are eligible to receive logs, as in example 1—gets the CloudTrail log reporting the event. However, the bucket owner doesn't get the ACL configuration information, specifically the grantee email address and the grant. The only information that the log tells the bucket owner is that an ACL API call was made by Account B.

CloudTrail log file entries for Amazon S3 and S3 on Outposts

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

> **Note**
>
> To view CloudTrail log file examples for Amazon S3 Express One Zone, see CloudTrail log file examples for S3 Express One Zone.

For more information, see the following examples.

```

Enabling CloudTrail event logging for S3 buckets and objects

You can use CloudTrail data events to get information about bucket and object-level requests in Amazon S3. To enable CloudTrail data events for all of your buckets or for a list of specific buckets, you must create a trail manually in CloudTrail.

Note

- The default setting for CloudTrail is to find only management events. Check to ensure that you have the data events enabled for your account.

- With an S3 bucket that is generating a high workload, you could quickly generate thousands of logs in a short amount of time. Be mindful of how long you choose to enable CloudTrail data events for a busy bucket.

CloudTrail stores Amazon S3 data event logs in an S3 bucket of your choosing. Consider using a bucket in a separate AWS account to better organize events from multiple buckets that you might own into a central place for easier querying and analysis. AWS Organizations helps you create an AWS account that is linked to the account that owns the bucket that you're monitoring. For more information, see What is AWS Organizations? in the *AWS Organizations User Guide*.

When you log data events for a trail in CloudTrail, you can choose to use advanced event selectors or basic event selectors to log data events for objects stored in general purpose buckets. To log data events for objects stored in directory buckets, you must use advanced event selectors. For more information, see Logging with AWS CloudTrail for S3 Express One Zone.

When you create a trail in the CloudTrail console using advanced event selectors, in the data events section, you can choose **Log all events** for the **Log selector template** to log all object-level events. When you create a trail in the CloudTrail console using basic event selectors, in the data events section, you can select the **Select all S3 buckets in your account** check box to log all object-level events.

Note

- It's a best practice to create a lifecycle configuration for your AWS CloudTrail data event bucket. Configure the lifecycle configuration to periodically remove log files after the period of time you believe you need to audit them. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see Setting an S3 Lifecycle configuration on a bucket.
- For more information about logging format, see Logging Amazon S3 API calls using AWS CloudTrail.
- For examples of how to query CloudTrail logs, see the *AWS Big Data Blog* post Analyze Security, Compliance, and Operational Activity Using AWS CloudTrail and Amazon Athena.

Enable logging for objects in a bucket using the console

You can use the AWS CloudTrail console to configure a CloudTrail trail to log data events for objects in an S3 bucket. CloudTrail supports logging Amazon S3 object-level API operations such as `GetObject`, `DeleteObject`, and `PutObject`. These events are called *data events*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for S3 buckets that you specify, or to log data events for all the Amazon S3 buckets in your AWS account. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

CloudTrail does not populate data events in the CloudTrail event history. Additionally, not all bucket-level actions are populated in the CloudTrail event history. For more information about the Amazon S3 bucket–level API actions tracked by CloudTrail logging, see Amazon S3 bucket-level actions that are tracked by CloudTrail logging. For more information about how to query CloudTrail logs, see the AWS Knowledge Center article about using Amazon CloudWatch Logs filter patterns and Amazon Athena to query CloudTrail logs.

> **Note**
>
> If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see AWS CLI examples for filtering data events in the *AWS CloudTrail User Guide*.

To enable CloudTrail data events logging for objects in an S3 general purpose bucket or an S3 directory bucket see Creating a trail with the CloudTrail console in the *AWS CloudTrail User Guide*.

For more information about logging objects in an S3 directory bucket, see Logging with AWS CloudTrail for directory buckets.

For information about using the CloudTrail console to configure a trail to log S3 data events, see Logging data events in the *AWS CloudTrail User Guide*.

To disable CloudTrail data events logging for objects in an S3 bucket, see Deleting a trail with the CloudTrail console in the *AWS CloudTrail User Guide*.

Important

Additional charges apply for data events. For more information, see AWS CloudTrail pricing.

For more information about CloudTrail logging with S3 buckets, see the following topics:

- Creating a general purpose bucket
- Viewing the properties for an S3 general purpose bucket
- Logging Amazon S3 API calls using AWS CloudTrail
- Working with CloudTrail log files in the *AWS CloudTrail User Guide*

Identifying Amazon S3 requests using CloudTrail

In Amazon S3, you can identify requests using an AWS CloudTrail event log. AWS CloudTrail is the preferred way of identifying Amazon S3 requests, but if you are using Amazon S3 server access logs, see the section called "Identifying S3 requests".

Topics

- Identifying requests made to Amazon S3 in a CloudTrail log
- Identifying Amazon S3 Signature Version 2 requests by using CloudTrail
- Identifying access to S3 objects by using CloudTrail

Identifying requests made to Amazon S3 in a CloudTrail log

After you set up CloudTrail to deliver events to a bucket, you should start to see objects go to your destination bucket on the Amazon S3 console. These are formatted as follows:

`s3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/Region/yyyy/mm/dd`

Events logged by CloudTrail are stored as compressed, gzipped JSON objects in your S3 bucket. To efficiently find requests, you should use a service like Amazon Athena to index and query the CloudTrail logs.

For more information about CloudTrail and Athena, see Creating the table for AWS CloudTrail logs in Athena using partition projection in the *Amazon Athena User Guide*.

Identifying Amazon S3 Signature Version 2 requests by using CloudTrail

You can use a CloudTrail event log to identify which API signature version was used to sign a request in Amazon S3. This capability is important because support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use *Signature Version 4* signing.

We *strongly* recommend that you use CloudTrail to help determine whether any of your workflows are using Signature Version 2 signing. Remediate them by upgrading your libraries and code to use Signature Version 4 instead to prevent any impact to your business.

For more information, see Announcement: AWS CloudTrail for Amazon S3 adds new fields for enhanced security auditing in AWS re:Post.

> **Note**
>
> CloudTrail events for Amazon S3 include the signature version in the request details under the key name of `'additionalEventData`. To find the signature version on requests made for objects in Amazon S3 such as `GET`, `PUT`, and `DELETE` requests, you must enable CloudTrail data events. (This feature is turned off by default.)

AWS CloudTrail is the preferred method for identifying Signature Version 2 requests. If you're using Amazon S3 server-access logs, see Identifying Signature Version 2 requests.

Topics

- Athena query examples for identifying Amazon S3 Signature Version 2 requests
- Partitioning Signature Version 2 data

Athena query examples for identifying Amazon S3 Signature Version 2 requests

Example— Select all Signature Version 2 events, and print only EventTime, S3_Action, Request_Parameters, Region, SourceIP, and UserAgent

In the following Athena query, replace *`s3_cloudtrail_events_db.cloudtrail_table`* with your Athena details, and increase or remove the limit as needed.

```
SELECT EventTime, EventName as S3_Action, requestParameters as Request_Parameters,
 awsregion as AWS_Region, sourceipaddress as Source_IP, useragent as User_Agent
FROM s3_cloudtrail_events_db.cloudtrail_table
WHERE eventsource='s3.amazonaws.com'
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
LIMIT 10;
```

Example— Select all requesters that are sending Signature Version 2 traffic

```
SELECT useridentity.arn, Count(requestid) as RequestCount
FROM s3_cloudtrail_events_db.cloudtrail_table
WHERE eventsource='s3.amazonaws.com'
    and json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
Group by useridentity.arn
```

Partitioning Signature Version 2 data

If you have a large amount of data to query, you can reduce the costs and running time of Athena by creating a partitioned table.

To do this, create a new table with partitions as follows.

```
CREATE EXTERNAL TABLE s3_cloudtrail_events_db.cloudtrail_table_partitioned(
     eventversion STRING,
     userIdentity STRUCT<
         type:STRING,
         principalid:STRING,
         arn:STRING,
         accountid:STRING,
         invokedby:STRING,
         accesskeyid:STRING,
         userName:STRING,
       sessioncontext:STRUCT<
                  attributes:STRUCT<
                  mfaauthenticated:STRING,
                  creationdate:STRING>,
                  sessionIssuer:STRUCT<
                  type:STRING,
```

```
                    principalId:STRING,
                    arn:STRING,
                    accountId:STRING,
                    userName:STRING>
                >
            >,
        eventTime STRING,
        eventSource STRING,
        eventName STRING,
        awsRegion STRING,
        sourceIpAddress STRING,
        userAgent STRING,
        errorCode STRING,
        errorMessage STRING,
        requestParameters STRING,
        responseElements STRING,
        additionalEventData STRING,
        requestId STRING,
        eventId STRING,
        resources ARRAY<STRUCT<ARN:STRING,accountId: STRING,type:STRING>>,
        eventType STRING,
        apiVersion STRING,
        readOnly STRING,
        recipientAccountId STRING,
        serviceEventDetails STRING,
        sharedEventID STRING,
        vpcEndpointId STRING
    )
    PARTITIONED BY (region string, year string, month string, day string)
    ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'
    STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
    OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
    LOCATION 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/';
```

Then, create the partitions individually. You can't get results from dates that you haven't created.

```
ALTER TABLE s3_cloudtrail_events_db.cloudtrail_table_partitioned ADD
    PARTITION (region= 'us-east-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-east-1/2019/02/19/'
    PARTITION (region= 'us-west-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-1/2019/02/19/'
```

```
    PARTITION (region= 'us-west-2', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-2/2019/02/19/'
    PARTITION (region= 'ap-southeast-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-1/2019/02/19/'
    PARTITION (region= 'ap-southeast-2', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-2/2019/02/19/'
    PARTITION (region= 'ap-northeast-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-northeast-1/2019/02/19/'
    PARTITION (region= 'eu-west-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/eu-west-1/2019/02/19/'
    PARTITION (region= 'sa-east-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/sa-east-1/2019/02/19/';
```

You can then make the request based on these partitions, and you don't need to load the full bucket.

```
SELECT useridentity.arn,
Count(requestid) AS RequestCount
FROM s3_cloudtrail_events_db.cloudtrail_table_partitioned
WHERE eventsource='s3.amazonaws.com'
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
AND region='us-east-1'
AND year='2019'
AND month='02'
AND day='19'
Group by useridentity.arn
```

Identifying access to S3 objects by using CloudTrail

You can use your AWS CloudTrail event logs to identify Amazon S3 object access requests for data events such as `GetObject`, `DeleteObject`, and `PutObject`, and discover additional information about those requests.

> **Note**
>
> If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude

the additional visibility about deleted objects from the event record. For more information, see AWS CLI examples for filtering data events in the *AWS CloudTrail User Guide.*

The following example shows how to get all PUT object requests for Amazon S3 from an AWS CloudTrail event log.

Topics

- Athena query examples for identifying Amazon S3 object access requests

Athena query examples for identifying Amazon S3 object access requests

In the following Athena query examples, replace *s3_cloudtrail_events_db.cloudtrail_table* with your Athena details, and modify the date range as needed.

Example— Select all events that have PUT object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  eventName = 'PutObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example— Select all events that have GET object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
```

```
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  eventName = 'GetObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example— Select all anonymous requester events to a bucket in a certain period and print only EventTime, EventName, EventSource, SourceIP, UserAgent, BucketName, UserARN, and AccountID

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  userIdentity.arn as userArn,
  userIdentity.accountId
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  userIdentity.accountId = 'anonymous'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example— Identify all requests that required an ACL for authorization

The following Amazon Athena query example shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. If the request required an ACL for authorization, the `aclRequired` value in `additionalEventData` is `Yes`. If no ACLs were required, `aclRequired` is not present. You can use this information to migrate those ACL permissions to the appropriate bucket policies. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see Prerequisites for disabling ACLs.

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  userIdentity.arn as userArn,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  json_extract_scalar(additionalEventData, '$.aclRequired') as aclRequired
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  json_extract_scalar(additionalEventData, '$.aclRequired') = 'Yes'
  AND eventTime BETWEEN '2022-05-10T00:00:00Z' and '2022-08-10T00:00:00Z'
```

Note

- These query examples can also be useful for security monitoring. You can review the results for `PutObject` or `GetObject` calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.

If you are using Amazon S3 server access logs, see Identifying object access requests.

Logging requests with server access logging

Server access logging provides detailed records for the requests that are made to a bucket. Server access logs can be used for operational analysis, to understand your security posture, and to charge back users.

Amazon S3 periodically collects access log records, consolidates them, and delivers them to your chosen destination. You can deliver logs to Amazon CloudWatch Logs or to an Amazon S3 general purpose bucket.

> **Note**
>
> Server access logs don't record information about wrong-Region redirect errors for Regions that launched after March 20, 2019. Wrong-Region redirect errors occur when a request for an object or bucket is made outside the Region in which the bucket exists.

Delivery options

You can deliver server access logs to two destinations. You can use one or both.

- **Amazon CloudWatch Logs** – Delivers logs in structured format to a CloudWatch Logs log group. You can query logs with CloudWatch Logs Insights, aggregate logs across accounts and Regions, and encrypt logs with AWS KMS. From the log group, you can also deliver logs to Amazon S3 in JSON or Apache Parquet format, or mirror logs to S3 Tables in Apache Iceberg format for SQL analytics. CloudWatch vended logs ingestion rates apply.
- **Amazon S3 general purpose bucket** – Delivers logs in space-delimited text format to an Amazon S3 bucket you specify. There is no charge for log delivery. You pay only for the storage of the log files. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

The following table compares the two delivery options.

Comparing server access log delivery options

Capability	Amazon CloudWatch Logs	Amazon S3 general purpose bucket
Destinations	CloudWatch Logs log group, Amazon S3 (JSON or Parquet), or Amazon Data Firehose. The CloudWatch Logs log group delivery can be extended to mirror logs to S3 Tables in Iceberg format.	Amazon S3 bucket (space-de limited text)
Log format	Structured JSON (log group), JSON or Apache Parquet	Space-delimited text

Capability	Amazon CloudWatch Logs	Amazon S3 general purpose bucket
	(Amazon S3), Apache Iceberg (S3 Tables)	
Querying	CloudWatch Logs Insights (log group), Amazon Athena or Spark (S3 Tables)	Amazon Athena
SQL analytics through S3 Tables	Yes (automatic Iceberg mirror)	No (requires ETL)
Cross-account aggregation	Yes (Amazon S3 and Firehose destinations support cross-account delivery)	No (same account only)
Cross-Region aggregation	Yes (Amazon S3 and Firehose destinations support cross-Region delivery)	No (same Region only)
AWS KMS encryption	Yes	No (SSE-S3 only)
Setup	CloudWatch Logs APIs or Amazon S3 console	Amazon S3 API (`PutBucketLogging`) or console
Delivery latency	Within a few hours	Within a few hours

Best-effort server log delivery

Server access log records are delivered on a best-effort basis. Most requests for a bucket that is properly configured for logging result in a delivered log record. Most log records are delivered within a few hours of the time that they are recorded, but they can be delivered more frequently.

The completeness and timeliness of server logging is not guaranteed. The log record for a particular request might be delivered long after the request was actually processed, or *it might not be delivered at all*. It is possible that you might even see a duplication of a log record. The purpose of server logs is to give you an idea of the nature of traffic against your bucket. Although log

records are rarely lost or duplicated, be aware that server logging is not meant to be a complete accounting of all requests.

Because of the best-effort nature of server logging, your usage reports might include one or more access requests that do not appear in a delivered server log. You can find these usage reports under **Cost & usage reports** in the AWS Billing and Cost Management console.

Bucket logging status changes take effect over time

Changes to the logging status of a bucket take time to actually affect the delivery of log files. For example, if you enable logging for a bucket, some requests made in the following hour might be logged, and others might not. Suppose that you change the destination bucket for logging from bucket A to bucket B. For the next hour, some logs might continue to be delivered to bucket A, whereas others might be delivered to the new destination bucket B. Similarly, if you change the CloudWatch Logs log group used for delivery, some logs might continue to be delivered to the previous log group during the transition. In all cases, the new settings eventually take effect without any further action on your part.

Pricing

The cost of server access logging depends on which delivery option you use.

- **Amazon CloudWatch Logs** – You pay for ingestion at CloudWatch vended logs rates, with volume-based tiered pricing. CloudWatch Logs compresses logs before storage, so stored volume is significantly less than ingested volume. If you enable the S3 Tables mirror, there is no additional charge for storage or table maintenance. You pay only for query requests at S3 Tables pricing. For current rates, see CloudWatch pricing.
- **Amazon S3 general purpose bucket** – There is no charge for log delivery. You pay only for the storage of the log files at standard Amazon S3 storage rates. We do not assess data-transfer charges for log file delivery, but we do charge the normal data-transfer rate for accessing the log files. For current rates, see Amazon S3 pricing.

For more information about delivering and using server access logs, see the following sections.

Delivering logs to Amazon CloudWatch Logs

When you deliver server access logs to Amazon CloudWatch Logs, you get structured JSON logs that you can query interactively with CloudWatch Logs Insights, aggregate across accounts and

Regions, and optionally mirror to S3 Tables in Apache Iceberg format for SQL analytics. You can also deliver logs to Amazon S3 in JSON or Apache Parquet format or route them through Amazon Data Firehose.

- Managing log retention
- Querying logs with CloudWatch Logs Insights
- Querying access logs in S3 Tables
- Troubleshooting CloudWatch Logs delivery

Delivering server access logs to CloudWatch Logs

You can deliver Amazon S3 server access logs to a CloudWatch Logs log group using Amazon CloudWatch Logs vended log delivery. Once logs are in CloudWatch Logs, you can query them with CloudWatch Logs Insights, aggregate them across accounts and Regions, encrypt them with AWS Key Management Service (AWS KMS), and optionally deliver them to Amazon S3 Tables in Apache Iceberg format for SQL analytics. You can also deliver logs to Amazon S3 in JSON or Apache Parquet format or route them through Amazon Data Firehose.

You configure delivery using CloudWatch Logs APIs, not Amazon S3 APIs. You specify a log group for each source bucket. Multiple buckets can share the same log group, or each bucket can deliver to its own.

Tip

You can set up multiple destinations for the same bucket. For example, deliver to a CloudWatch Logs log group for interactive querying and simultaneously deliver to Amazon S3 in Parquet format for long-term retention at lower cost.

Note

CloudWatch Logs vended log delivery also supports Amazon Data Firehose and Amazon S3 as delivery destinations, including Apache Parquet output format. This page covers the CloudWatch Logs log group destination, which also supports the S3 Tables integration for

SQL analytics. For information about Firehose and Amazon S3 destinations, see Enable logging from AWS services in the *Amazon CloudWatch Logs User Guide*.

Note

For information about delivering server access logs to an Amazon S3 general purpose bucket instead, see Enabling Amazon S3 server access logging.

Prerequisites

Before you set up delivery, you need the following:

- An Amazon S3 general purpose bucket (the source bucket you want to log).
- A CloudWatch Logs log group in the same AWS Region as the source bucket.
- IAM permissions for the caller. At a minimum, you need the following permissions:
  - `logs:PutDeliverySource`
  - `logs:PutDeliveryDestination`
  - `logs:CreateDelivery`
  - `s3:AllowVendedLogDeliveryForResource` (on the source bucket)

  If you plan to enable the S3 Tables integration, you also need:
  - `observabilityadmin:CreateS3TableIntegration`
  - `logs:AssociateSourceToS3TableIntegration`
  - `s3tables:CreateTableBucket`
  - `s3tables:PutTableBucketEncryption`
  - `s3tables:PutTableBucketPolicy`

Setting up delivery (AWS CLI)

To set up server access log delivery to CloudWatch Logs using the AWS Command Line Interface, complete the following three steps.

1. **Create a delivery source.** This registers your Amazon S3 bucket as a log source with CloudWatch Logs.

```
aws logs put-delivery-source \
  --name my-sal-source \
  --resource-arn arn:aws:s3:::my-bucket \
  --log-type S3_SERVER_ACCESS_LOGS
```

2. **Create a delivery destination.** This specifies the CloudWatch Logs log group where logs will be delivered.

```
aws logs put-delivery-destination \
  --name my-sal-destination \
  --delivery-destination-configuration '{"destinationResourceArn":
 "arn:aws:logs:us-east-1:123456789012:log-group:my-sal-logs"}'
```

3. **Create a delivery.** This links the source to the destination and starts log delivery.

```
aws logs create-delivery \
  --delivery-source-name my-sal-source \
  --delivery-destination-arn arn:aws:logs:us-east-1:123456789012:delivery-
destination:my-sal-destination
```

After you complete these steps, Amazon S3 begins delivering server access logs to your CloudWatch Logs log group. The configuration takes 15–20 minutes to propagate. After propagation, log delivery typically begins within a few hours. Only new requests are logged – there is no backfill of historical data.

Setting up delivery (Amazon S3 console)

1. Sign in to the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. Choose the name of the source bucket that you want to enable logging for.
4. Choose the **Properties** tab.
5. In the **Server access log delivery to CloudWatch Logs** section, choose **Edit**.
6. Choose **Enable**.
7. Select or create a CloudWatch Logs log group as the delivery destination.
8. (Optional) To deliver logs to S3 Tables in Apache Iceberg format, select **Enable S3 Tables integration**.
9. Choose **Save changes**.

After you save, the **Server access log delivery to CloudWatch Logs** section displays the enabled log group.

Setting up delivery (CloudFormation)

You can use AWS CloudFormation to automate the setup of server access log delivery to CloudWatch Logs. The following template creates the required resources: an IAM role, a CloudWatch Logs log group, a delivery source, a delivery destination, and a delivery.

```
AWSTemplateFormatVersion: '2010-09-09'
Description: S3 Access Logs delivery to CloudWatch Logs

Parameters:
  SourceBucketArn:
    Type: String
    Description: ARN of the S3 bucket to enable access logging
  LogGroupName:
    Type: String
    Default: /aws/s3/access-logs
    Description: CloudWatch Log Group name for SAL delivery

Resources:
  SALLogGroup:
    Type: AWS::Logs::LogGroup
    Properties:
      LogGroupName: !Ref LogGroupName
      RetentionInDays: 180

  SALDeliverySource:
    Type: AWS::Logs::DeliverySource
    Properties:
      Name: !Sub '${AWS::StackName}-sal-source'
      ResourceArn: !Ref SourceBucketArn
      LogType: S3_SERVER_ACCESS_LOGS

  SALDeliveryDestination:
    Type: AWS::Logs::DeliveryDestination
    Properties:
      Name: !Sub '${AWS::StackName}-sal-destination'
      DestinationResourceArn: !GetAtt SALLogGroup.Arn

  SALDelivery:
    Type: AWS::Logs::Delivery
```

```
    Properties:
      DeliverySourceName: !Ref SALDeliverySource
      DeliveryDestinationArn: !GetAtt SALDeliveryDestination.Arn
```

Enabling the S3 Tables integration (optional)

When you enable the S3 Tables integration, CloudWatch Logs automatically delivers your server access logs in Apache Iceberg format to the `aws-cloudwatch` managed table bucket in your account. You can then query this data using Amazon Athena, Amazon Redshift, or any Iceberg-compatible tool.

There is no additional charge for storage or table maintenance in the S3 Tables integration. You pay only for CloudWatch Logs ingestion and for query requests at S3 Tables pricing.

1. **Create the S3 Tables integration** (once per account per Region).

   ```
   aws observabilityadmin create-s3-table-integration \
     --role-arn arn:aws:iam::123456789012:role/CWLogsS3TableIntegrationRole \
     --encryption '{"SseAlgorithm": "AES256"}'
   ```

   The IAM role must trust the `logs.amazonaws.com` service principal and grant the `logs:integrateWithS3Table` permission. The following is an example trust policy:

   ```
         {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "logs.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
           "StringEquals": {
             "aws:SourceAccount": "123456789012"
           },
           "ArnLike": {
             "aws:SourceArn": "arn:aws:logs:us-east-1:123456789012:log-group:log-
   group-name"
           }
         }
       }
   ```

```
  ]
}
```

The role also needs the following permission policy:

```
      {
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:integrateWithS3Table",
      "Resource": "arn:aws:logs:us-east-1:123456789012:log-group:log-group-name",
      "Condition": {
        "StringEquals": {
          "aws:ResourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

2. **Associate your delivery source to the integration.**

```
aws logs associate-source-to-s3-table-integration \
  --integration-arn integration-arn \
  --data-source '{"name":"amazon_s3","type":"server_access"}'
```

After these steps, CloudWatch Logs creates the `aws-cloudwatch` managed table bucket and begins delivering logs in Iceberg format. Data typically appears within an hour of the first delivery to CloudWatch Logs.

For information about querying the S3 Tables integration, see Querying access logs in S3 Tables.

Cross-account and cross-Region aggregation

The CloudWatch Logs delivery path supports cross-account and cross-Region log aggregation with two options:

- **CloudWatch cross-account observability** allows you to query logs in place across accounts without copying data.

- **CloudWatch Logs centralization** allows you to consolidate logs from multiple accounts and Regions into a central log group, optionally using subscription filters for selective forwarding.

For multi-account setups, administrators can use CloudWatch Telemetry Config enablement rules with AWS Organizations to automatically enable server access log delivery across member accounts.

> **Note**
>
> Enablement rules do not currently support automatic enablement of the S3 Tables integration. You must enable the integration separately in each account.

Encryption

You can encrypt server access logs delivered to CloudWatch Logs by configuring AWS KMS encryption on your log group. When server access logs are delivered to that log group, they are encrypted with your AWS KMS key. This addresses a key limitation of the Amazon S3 general purpose bucket delivery path, which supports only SSE-S3 encryption.

If you enable the S3 Tables integration with a AWS KMS-encrypted log group, you must grant additional permissions in your AWS KMS key policy to the following service principals:

```
     {
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "EnableCWSystemTablesKeyUsage",
    "Effect": "Allow",
    "Principal": {
      "Service": "systemtables.cloudwatch.amazonaws.com"
    },
    "Action": [
      "kms:DescribeKey",
      "kms:GenerateDataKey",
      "kms:Decrypt"
    ],
    "Resource": "arn:aws:kms:us-east-1:123456789012:key/key-id",
    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
```

```
        }
      }
    },
    {
      "Sid": "EnableS3TablesMaintenanceKeyUsage",
      "Effect": "Allow",
      "Principal": {
        "Service": "maintenance.s3tables.amazonaws.com"
      },
      "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
      ],
      "Resource": "arn:aws:kms:us-east-1:123456789012:key/key-id",
      "Condition": {
        "StringLike": {
          "kms:EncryptionContext:aws:s3:arn": "table-bucket-arn/*"
        }
      }
    }
  ]
}
```

The `systemtables.cloudwatch.amazonaws.com` principal is used by CloudWatch Logs to write logs to S3 Tables. The `maintenance.s3tables.amazonaws.com` principal is used by S3 Tables for Iceberg operations such as compaction.

Disabling delivery

To stop delivering server access logs to CloudWatch Logs, you can delete the delivery or the delivery source:

- **Delete the delivery** – stops log delivery but keeps the delivery source configuration intact. You can create a new delivery later without reconfiguring the source.

```
aws logs delete-delivery \
  --id delivery-id
```

- **Delete the delivery source** – removes the source configuration entirely. Use this if you no longer want the bucket associated with CloudWatch Logs delivery.

```
aws logs delete-delivery-source \
```

```
--name delivery-source-name
```

Previously delivered logs remain in the log group and in the S3 Tables integration (if enabled). Deleting the delivery does not remove existing log data.

Log format in CloudWatch Logs

When Amazon S3 server access logs are delivered to Amazon CloudWatch Logs, each log record is a structured JSON object. This is different from the space-delimited text format used for delivery to an Amazon S3 general purpose bucket. The structured format makes fields directly queryable in CloudWatch Logs Insights without regex parsing.

> **Note**
>
> For the space-delimited text format used for general purpose bucket delivery, see Amazon S3 server access log format.

Log record fields

The following table describes the fields in each server access log record delivered to CloudWatch Logs.

Server access log fields in CloudWatch Logs

Field	Type	Description
`schema_version_id`	string	Version identifier for the log record schema (for example, `V_1_0`). Use this field to detect schema changes when new fields are added in future versions.
`bucket_arn`	string	ARN of the source bucket.
`bucket_name`	string	Name of the bucket that the request was made to. Derived from the bucket ARN.
`request_time`	string	Time the request was received, in UTC. Formatted as ISO 8601 (`yyyy-MM-dd'T'HH:mm:ss.SSS'Z`

Field	Type	Description
		'). In the S3 Tables integration (Iceberg), this field is stored as `timestamptz` .
`bucket_owner_id`	string	Canonical user ID of the owner of the source bucket.
`remote_ip`	string	Apparent IP address of the requester. Defaults to `null` if not available.
`requester`	string	Canonical user ID of the requester, or `null` for unauthenticated requests. For IAM users and roles, this is the ARN.
`request_id`	string	Unique identifier generated by Amazon S3 for each request. Defaults to `null` if not available.
`operation`	string	The operation that was performed, for example `REST.GET.OBJECT` or `REST.PUT.OBJECT` . Defaults to `null` if not available.
`key_name`	string	Object key in the request, or `null` if the operation does not involve an object.
`request_uri`	string	The `Request-URI` part of the HTTP request message, or `null` if not available.
`http_status`	int	Numeric HTTP status code of the response, for example `200` or `403`. Defaults to `null` if not available.
`error_code`	string	Amazon S3 error code, for example `NoSuchKey` or `AccessDenied` , or `null` if no error occurred.
`bytes_sent_size`	long	Number of response bytes sent, excluding HTTP protocol overhead. Defaults to `null` if not available .

Field	Type	Description
object_size	long	Total size of the object. Defaults to null if not available.
total_duration	long	Total time of the request from the time the request was received to the last byte of the response sent, in milliseconds. Defaults to null if not available.
turn_around_duration	long	Time Amazon S3 spent processing the request, in milliseconds. This value is measured from the time the last byte of the request was received until the time the first byte of the response was sent. Defaults to null if not available.
referer	string	Value of the HTTP Referer header, or null if not present.
user_agent	string	Value of the HTTP User-Agent header. Defaults to null if not available.
version_id	string	Version ID in the request, or null if the operation does not involve a versioned object.
host_id	string	Amazon S3 extended request ID (x-amz-id-2). Defaults to null if not available.
signature_version	string	Signature version used to authenticate the request: SigV2 or SigV4. Defaults to null for unauthenticated requests.
cipher_suite	string	TLS cipher suite negotiated for HTTPS requests, or null for HTTP.
authentication_type	string	Type of request authentication: AuthHeader , QueryString , or null.
host_header	string	Endpoint used to connect to Amazon S3. Defaults to null if not available.

Field	Type	Description
`tls_version`	string	TLS version negotiated by the client: `TLSv1.1`, `TLSv1.2`, `TLSv1.3`, or `null`.
`access_point_arn`	string	ARN of the access point used for the request, or `null` if the request did not use an access point.
`acl_required`	boolean	Whether an ACL was required for the request. Defaults to `null` when not applicable.
`source_region`	string	AWS Region from which the request originated, or `null` when the origin Region cannot be determined. Examples include PrivateLink connections, Direct Connect connections, Bring your own IP addresses (BYOIP), non-AWS IP addresses, and logs generated by policy-based actions such as lifecycle and checksum.

Sample log record

The following is an example of a server access log record as it appears in CloudWatch Logs.

```
{
  "schema_version_id": "V_1_0",
  "bucket_arn": "arn:aws:s3:::my-data-bucket",
  "bucket_name": "my-data-bucket",
  "request_time": "2026-04-29T14:32:16.000Z",
  "bucket_owner_id":
 "79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be",
  "remote_ip": "203.0.113.45",
  "requester": "arn:aws:iam::123456789012:role/DataAnalystRole",
  "request_id": "3E57427F33A59F07",
  "operation": "REST.GET.OBJECT",
  "key_name": "reports/2026/quarterly-summary.parquet",
  "request_uri": "GET /my-data-bucket/reports/2026/quarterly-summary.parquet HTTP/1.1",
  "http_status": 200,
  "error_code": null,
  "bytes_sent_size": 1048576,
  "object_size": 1048576,
```

```
  "total_duration": 45,
  "turn_around_duration": 12,
  "referer": null,
  "user_agent": "aws-sdk-java/2.20.0",
  "version_id": null,
  "host_id": "s9lzHYrFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/
VLi31234=",
  "signature_version": "SigV4",
  "cipher_suite": "TLS_AES_128_GCM_SHA256",
  "authentication_type": "AuthHeader",
  "host_header": "my-data-bucket.s3.us-east-1.amazonaws.com",
  "tls_version": "TLSv1.3",
  "access_point_arn": null,
  "acl_required": false,
  "source_region": "us-east-1"
}
```

Differences from general purpose bucket log format

The CloudWatch Logs log format differs from the general purpose bucket log format in the following ways:

- **Format** – CloudWatch Logs logs are structured JSON objects. General purpose bucket logs are space-delimited text.
- **Field names** – The CloudWatch Logs format uses descriptive underscore-separated field names (for example, `bytes_sent_size`, `total_duration`, `key_name`, `authentication_type`). The general purpose bucket format is positional space-delimited text with no named columns.
- **Additional fields** – The CloudWatch Logs format includes `schema_version_id` and `bucket_arn`, which are not present in the general purpose bucket text format.
- **No parsing required** – Because CloudWatch Logs logs are structured JSON, you can query individual fields directly in CloudWatch Logs Insights without regex parsing. The general purpose bucket text format requires a regex or custom parser to extract fields.

Managing log retention

When you deliver server access logs to CloudWatch Logs, log retention is controlled by the retention setting on the log group. You set retention when you create the log group, or update it at any time using the CloudWatch Logs console, AWS CLI, or API.

Retention options range from 1 day to 10 years, or you can choose to never expire logs. When log data reaches the end of its retention period, it is automatically deleted from the log group.

If you have enabled the S3 Tables mirror for your log group, the mirrored data in the S3 table follows the same retention. When log data expires from the log group, the corresponding records are removed from the S3 table. You do not need to manage retention separately for the S3 table.

To set or update log group retention

1. Open the CloudWatch Logs console at CloudWatch Logs console.
2. Select the log group that receives your server access logs.
3. Choose **Actions**, then **Edit retention setting**.
4. Select a retention period and choose **Save**.

To set retention using the AWS CLI:

```
aws logs put-retention-policy \
  --log-group-name "/aws/vendedlogs/s3/DOC-EXAMPLE-BUCKET/S3_SERVER_ACCESS_LOGS" \
  --retention-in-days 90
```

For more information, see Change log data retention in CloudWatch Logs in the *CloudWatch Logs User Guide*.

Querying logs with CloudWatch Logs Insights

CloudWatch Logs Insights lets you interactively search and analyze your server access log data. Queries run against the log group where your logs are delivered and return results in seconds.

> **Note**
>
> For querying logs delivered to an Amazon S3 general purpose bucket, see Querying access logs for requests by using Amazon Athena. For querying the S3 Tables mirror with SQL, see Querying access logs in S3 Tables.

Getting started

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Logs**, then **Logs Insights**.
3. Select your server access log group from the log group selector.
4. Choose a time range for your query.
5. Enter a query and choose **Run query**.

Traffic analysis

The following queries help you understand request volume and traffic patterns.

Example Request volume over time

```
stats count(*) as requests by bin(5m) as interval
| sort interval asc
```

Example Request mix by operation type

```
stats count(*) as cnt by operation
| sort cnt desc
```

Example Traffic by bucket

```
stats count(*) as requests, sum(bytes_sent_size) as bytes_out by bucket_arn
| sort requests desc
```

Error troubleshooting

The following queries help you identify and diagnose errors.

Example Error rate breakdown

```
filter http_status >= 400
| stats count(*) as error_count by http_status, error_code, operation
| sort error_count desc
```

Example 403 Access Denied requests

```
filter http_status = 403
| stats count(*) as denied_count by key_name, remote_ip, requester
```

```
| sort denied_count desc
```

Example 404 Not Found requests

```
filter http_status = 404
| stats count(*) as miss_count by key_name, error_code, remote_ip
| sort miss_count desc
```

Example 503 SlowDown (throttling) events

```
filter http_status = 503
| stats count(*) as throttle_count by key_name, remote_ip
| sort throttle_count desc
```

Access patterns

The following queries help you understand who is accessing your data and how.

Example Traffic by source IP

```
stats count(*) as total_requests,
  sum(http_status >= 400) as errors,
  sum(bytes_sent_size) as bytes_transferred
  by remote_ip
| sort total_requests desc
```

Example Operations by requester

```
stats count(*) as requests by requester, operation
| sort requests desc
```

Example Most accessed keys

```
filter operation like /REST\.(GET|PUT)\.OBJECT/
| stats count(*) as access_count, sum(bytes_sent_size) as bytes_out by key_name
| sort access_count desc
| limit 10
```

Latency analysis

The following queries help you identify slow requests and latency trends.

Example Latency by operation type

```
filter operation like /REST\.(GET|PUT)\.OBJECT/
| stats avg(total_duration) as avg_ms,
  pct(total_duration, 50) as p50_ms,
  pct(total_duration, 95) as p95_ms,
  max(total_duration) as max_ms,
  count(*) as requests
  by operation
```

Example Slowest keys by p95 latency

```
filter operation like /REST\.GET\.OBJECT/
| stats avg(total_duration) as avg_ms,
  pct(total_duration, 95) as p95_ms,
  count(*) as requests
  by key_name
| sort p95_ms desc
| limit 10
```

Example Latency over time

```
filter operation like /REST\.(GET|PUT)\.OBJECT/
| stats avg(total_duration) as avg_ms, pct(total_duration, 95) as p95_ms by bin(5m) as
 interval
| sort interval asc
```

Cost attribution

The following queries help you understand data transfer and identify cost drivers.

Example Data transfer by operation

```
filter operation like /REST\.(GET|PUT|DELETE)\.OBJECT/
| stats sum(bytes_sent_size) as total_bytes_out,
  sum(object_size) as total_object_bytes,
  count(*) as request_count
  by operation
| sort total_bytes_out desc
```

Example Largest objects being served

```
filter operation like /REST\.GET\.OBJECT/ and bytes_sent_size > 0
| stats max(object_size) as max_size, avg(object_size) as avg_size, count(*) as reads
 by key_name
| sort max_size desc
| limit 10
```

Security analysis

The following queries help you detect suspicious access patterns.

Example IPs with high error rates

```
stats count(*) as total,
  sum(http_status >= 400) as errors
  by remote_ip
| filter errors > 10
| sort errors desc
```

Example Failed access attempts by key

```
filter http_status >= 400
| stats count(*) as attempts by remote_ip, key_name, operation, http_status
| sort attempts desc
| limit 20
```

Example TLS version distribution

```
stats count(*) as cnt by tls_version
| sort cnt desc
```

Querying access logs in S3 Tables

When you enable the Amazon S3 Tables integration, Amazon CloudWatch Logs delivers your server access logs in Apache Iceberg format to the `aws-cloudwatch` managed table bucket. Because the data is in Iceberg format, you can query it with any tool that supports Apache Iceberg, including:

- **Amazon Athena** – Run SQL queries directly from the Athena console using the S3 Tables catalog.
- **Amazon SageMaker Unified Studio** – Use the built-in SQL editor to query your log data alongside other analytics workloads.

- **Amazon Redshift** – Query Iceberg tables through Redshift Spectrum or direct integration.
- **Apache Spark on Amazon EMR** – Use Spark SQL or the DataFrame API with the Iceberg connector.
- **Open-source tools** – Any tool that supports the Apache Iceberg REST catalog, such as Trino, DuckDB, or PyIceberg.

> **Note**
>
> For querying logs interactively in CloudWatch Logs Insights (without SQL), see Querying logs with CloudWatch Logs Insights.

Prerequisites

Before you can query access logs in S3 Tables, you must complete the following:

1. **Enable the S3 Tables integration.** See Enabling the S3 Tables integration (optional).
2. **Enable S3 Tables integration with analytics services.** In the Amazon S3 console, navigate to **Table buckets** and choose **Enable integration**. This creates the `s3tablescatalog` federated catalog in Data Catalog and makes your tables visible to analytics services. By default, access is controlled through IAM permissions. You can optionally use AWS Lake Formation for fine-grained access control. For more information, see Integrating S3 Tables with AWS analytics services.
3. **Wait for data to populate.** Data typically appears within an hour of the first delivery to CloudWatch Logs.

Connecting Amazon Athena

1. Open the Athena console at https://console.aws.amazon.com/athena/.
2. In the query editor, select the **Amazon S3 Tables** catalog from the data source dropdown.
3. Your log tables appear in the database list under the `logs` namespace.

The table name for server access logs is `amazon_s3__server_access`. The fully qualified table reference is:

```
"s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
```

Traffic analysis

Example Request volume over time

```
SELECT date_trunc('minute', request_time) AS interval,
  COUNT(*) AS requests
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY date_trunc('minute', request_time)
ORDER BY interval ASC;
```

Example Request mix by operation type

```
SELECT operation, COUNT(*) AS cnt
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY operation
ORDER BY cnt DESC;
```

Example Traffic by bucket

```
SELECT bucket_arn, COUNT(*) AS requests, SUM(bytes_sent_size) AS bytes_out
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY bucket_arn
ORDER BY requests DESC;
```

Error troubleshooting

Example Error rate breakdown

```
SELECT http_status, error_code, operation, COUNT(*) AS error_count
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE http_status >= 400
GROUP BY http_status, error_code, operation
ORDER BY error_count DESC;
```

Example 403 Access Denied requests

```
SELECT key_name, remote_ip, requester, COUNT(*) AS denied_count
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE http_status = 403
```

```
GROUP BY key_name, remote_ip, requester
ORDER BY denied_count DESC;
```

Example 404 Not Found requests

```
SELECT key_name, error_code, remote_ip, COUNT(*) AS miss_count
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE http_status = 404
GROUP BY key_name, error_code, remote_ip
ORDER BY miss_count DESC;
```

Example 503 SlowDown (throttling) events

```
SELECT key_name, remote_ip, COUNT(*) AS throttle_count
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE http_status = 503
GROUP BY key_name, remote_ip
ORDER BY throttle_count DESC;
```

Access patterns

Example Traffic by source IP

```
SELECT remote_ip,
  COUNT(*) AS total_requests,
  SUM(CASE WHEN http_status >= 400 THEN 1 ELSE 0 END) AS errors,
  SUM(bytes_sent_size) AS bytes_transferred
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY remote_ip
ORDER BY total_requests DESC;
```

Example Operations by requester

```
SELECT requester, operation, COUNT(*) AS requests
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY requester, operation
ORDER BY requests DESC;
```

Example Most accessed keys

```
SELECT key_name, COUNT(*) AS access_count, SUM(bytes_sent_size) AS bytes_out
```

```
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE operation IN ('REST.GET.OBJECT', 'REST.PUT.OBJECT')
GROUP BY key_name
ORDER BY access_count DESC
LIMIT 10;
```

Latency analysis

Example Latency by operation type

```
SELECT operation,
  AVG(total_duration) AS avg_ms,
  APPROX_PERCENTILE(total_duration, 0.5) AS p50_ms,
  APPROX_PERCENTILE(total_duration, 0.95) AS p95_ms,
  MAX(total_duration) AS max_ms,
  COUNT(*) AS requests
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE operation IN ('REST.GET.OBJECT', 'REST.PUT.OBJECT')
GROUP BY operation;
```

Example Slowest keys by p95 latency

```
SELECT key_name,
  AVG(total_duration) AS avg_ms,
  APPROX_PERCENTILE(total_duration, 0.95) AS p95_ms,
  COUNT(*) AS requests
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE operation = 'REST.GET.OBJECT'
GROUP BY key_name
ORDER BY p95_ms DESC
LIMIT 10;
```

Example Latency over time

```
SELECT date_trunc('minute', request_time) AS interval,
  AVG(total_duration) AS avg_ms,
  APPROX_PERCENTILE(total_duration, 0.95) AS p95_ms
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE operation IN ('REST.GET.OBJECT', 'REST.PUT.OBJECT')
GROUP BY date_trunc('minute', request_time)
ORDER BY interval ASC;
```

Cost attribution

Example Data transfer by operation

```
SELECT operation,
  SUM(bytes_sent_size) AS total_bytes_out,
  SUM(object_size) AS total_object_bytes,
  COUNT(*) AS request_count
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE operation IN ('REST.GET.OBJECT', 'REST.PUT.OBJECT', 'REST.DELETE.OBJECT')
GROUP BY operation
ORDER BY total_bytes_out DESC;
```

Example Largest objects being served

```
SELECT key_name, MAX(object_size) AS max_size, AVG(object_size) AS avg_size, COUNT(*)
 AS reads
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE operation = 'REST.GET.OBJECT' AND bytes_sent_size > 0
GROUP BY key_name
ORDER BY max_size DESC
LIMIT 10;
```

Security analysis

Example IPs with high error rates

```
SELECT remote_ip,
  COUNT(*) AS total,
  SUM(CASE WHEN http_status >= 400 THEN 1 ELSE 0 END) AS errors
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY remote_ip
HAVING SUM(CASE WHEN http_status >= 400 THEN 1 ELSE 0 END) > 10
ORDER BY errors DESC;
```

Example Failed access attempts by key

```
SELECT remote_ip, key_name, operation, http_status, COUNT(*) AS attempts
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
WHERE http_status >= 400
GROUP BY remote_ip, key_name, operation, http_status
ORDER BY attempts DESC
```

```
LIMIT 20;
```

Example TLS version distribution

```
SELECT tls_version, COUNT(*) AS cnt
FROM "s3tablescatalog/aws-cloudwatch"."logs"."amazon_s3__server_access"
GROUP BY tls_version
ORDER BY cnt DESC;
```

Using AI agents to query Amazon S3 server access logs

MCP-compatible AI agents can discover the S3 tables that contain your Amazon S3 server access logs, generate SQL queries, and analyze the results. Because your Amazon S3 server access logs are exported as Iceberg tables in the `aws-cloudwatch` table bucket, agents can query them through the same S3 Tables catalog that you use with Amazon Athena, Amazon EMR, Amazon Redshift, or any Iceberg-compatible tool.

The Agent Toolkit for AWS provides skills that give agents validated procedures for working with AWS data. The Querying CloudWatch Logs system tables skill runs SQL queries on CloudWatch Logs data exported to S3 Tables, including your Amazon S3 server access logs in the `aws-cloudwatch` table bucket. To use it, download the skill from the repository on GitHub and add it to your agent's skills directory.

For example, you can ask an agent to show the top 10 source IP addresses by request count in your S3 server access logs over the last 24 hours. The agent uses the skill to locate the access log table and run the query in Athena.

Troubleshooting CloudWatch Logs delivery

Logs not appearing in CloudWatch Logs log group

If you have configured delivery but do not see logs in your CloudWatch Logs log group, check the following:

- **Verify the delivery is active.** Run `aws logs describe-deliveries` and confirm that your delivery shows a status of `ACTIVE`.
- **Verify the delivery source.** Run `aws logs describe-delivery-sources` and confirm that the source bucket ARN and log type (`S3_SERVER_ACCESS_LOGS`) are correct.
- **Confirm the source bucket has traffic.** Server access logs are only generated when requests are made to the source bucket. If the bucket has no traffic, no logs are produced.

- **Check the log group Region.** The log group must be in the same AWS Region as the source bucket.
- **Allow time for initial delivery.** After setup, it may take a few minutes for the first logs to appear.

S3 Tables integration not populating

If logs appear in CloudWatch Logs but the S3 Tables integration is empty, check the following:

- **Verify the integration exists.** In the CloudWatch console, go to **Settings**, **Global**, and confirm that an S3 Table Integration is listed.
- **Verify the source is associated.** Run `aws logs list-sources-for-s3-table-integration --integration-arn` *`integration-arn`* and confirm that your delivery source name and type appear in the list.
- **Check the service role permissions.** The IAM role used for the integration must have the `logs:integrateWithS3Table` permission scoped to your log group ARN. See Enabling the S3 Tables integration (optional).
- **Confirm the `aws-cloudwatch` table bucket exists.** In the Amazon S3 console, navigate to **Table buckets** and look for the `aws-cloudwatch` bucket. If it does not exist, the integration may not have completed successfully.
- **Allow time for data to appear.** The integration may lag behind CloudWatch Logs delivery. Data typically appears within an hour of the first delivery to CloudWatch Logs.
- **Check that the integration processes only new data.** The S3 Tables integration does not backfill logs from before the association was created. Only log events added after the association are delivered to S3 Tables.

Permission errors

The following are common permission errors and how to resolve them.

- **Access Denied on `PutDeliverySource`** – The caller needs the `logs:PutDeliverySource` and `s3:AllowVendedLogDeliveryForResource` permission.
- **Access Denied on `CreateDelivery`** – The caller needs the `logs:CreateDelivery` permission.
- **Access Denied on `CreateS3TableIntegration`** – The caller needs the `observabilityadmin:CreateS3TableIntegration` permission, plus `s3tables:CreateTableBucket`, `s3tables:PutTableBucketEncryption`, and `s3tables:PutTableBucketPolicy`.

- **AWS KMS errors on log group** – If your log group uses AWS KMS encryption, verify that the AWS KMS key policy grants access to the CloudWatch Logs service principal. See Encryption.
- **AWS KMS errors on S3 Tables integration** – If your log group uses AWS KMS encryption and the S3 Tables integration is enabled, verify that the AWS KMS key policy grants access to both `systemtables.cloudwatch.amazonaws.com` and `maintenance.s3tables.amazonaws.com`. See Encryption.
- **Access Denied when querying in Athena** – Verify that the IAM principal running the query has permissions to access the `aws-cloudwatch` table bucket and the S3 Tables catalog. If you are using AWS Lake Formation, verify that `SELECT` and `DESCRIBE` grants are in place.

Delivery stopped unexpectedly

If logs were previously being delivered but have stopped, check the following:

- **Source bucket deleted.** If the source bucket was deleted, delivery stops. If the bucket is recreated, you must create a new delivery again.
- **Log group deleted.** If the log group was deleted, delivery stops. Create a new log group and update the delivery destination.
- **IAM permissions revoked.** If the permissions required for delivery were removed, delivery may stop. Verify that the delivery configuration still has the required permissions.
- **Service quotas.** Check CloudWatch Logs service quotas for delivery limits per account. You may have reached the maximum number of deliveries.

Managing ingestion costs

If your CloudWatch Logs ingestion costs are higher than expected, consider the following:

- **Reduce retention.** Set a shorter retention period on the log group to reduce storage costs. CloudWatch Logs automatically deletes data that exceeds the retention period.
- **Review source bucket traffic.** High-traffic buckets generate more logs. Consider whether all source buckets need CloudWatch Logs delivery, or whether the free general purpose bucket delivery path is sufficient for some buckets.
- **Use volume-based pricing.** CloudWatch Logs vended logs ingestion pricing is tiered by volume. Higher volumes receive lower per-GB rates. For current rates, see CloudWatch pricing.

Delivering logs to an Amazon S3 general purpose bucket

When you deliver server access logs to an Amazon S3 general purpose bucket, logs are written in space-delimited text format. There is no charge for log delivery. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

Topics

- Enabling Amazon S3 server access logging
- Amazon S3 server access log format
- Managing log retention
- Using Amazon S3 server access logs to identify requests
- Troubleshoot server access logging

Enabling Amazon S3 server access logging

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

> **Note**
>
> This page covers delivering server access logs to an Amazon S3 general purpose bucket. You can also deliver logs to Amazon CloudWatch Logs for structured querying, cross-account aggregation, and optional mirroring to S3 Tables. For more information, see Delivering server access logs to CloudWatch Logs.

By default, Amazon S3 doesn't collect server access logs. When you enable logging, Amazon S3 delivers access logs for a source bucket to a destination bucket (also known as a *target bucket*) that you choose. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

An access log record contains details about the requests that are made to a bucket. This information can include the request type, the resources that are specified in the request, and the time and date that the request was processed. For more information about logging basics, see Logging requests with server access logging.

Important

- There is no extra charge for enabling server access logging on an Amazon S3 bucket. However, any log files that the system delivers to you will accrue the usual charges for storage. (You can delete the log files at any time.) We do not assess data-transfer charges for log file delivery, but we do charge the normal data-transfer rate for accessing the log files.
- Your destination bucket should not have server access logging enabled. You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. However, delivering logs to the source bucket will cause an infinite loop of logs and is not recommended. For simpler log management, we recommend that you save access logs in a different bucket.
- S3 buckets that have S3 Object Lock enabled can't be used as destination buckets for server access logs. Your destination bucket must not have a default retention period configuration.
- The destination bucket must not have Requester Pays enabled.

You can enable or disable server access logging by using the Amazon S3 console, Amazon S3 API, the AWS Command Line Interface (AWS CLI), or AWS SDKs.

Permissions for log delivery

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. For access log delivery, you must grant the logging service principal (`logging.s3.amazonaws.com`) access to your destination bucket.

To grant permissions to Amazon S3 for log delivery, you can use either a bucket policy or bucket access control lists (ACLs), depending on your destination bucket's S3 Object Ownership settings. However, we recommend that you use a bucket policy instead of ACLs.

Note

Granting `s3:PutObject` to the logging service principal is not sufficient if the destination bucket uses SSE-KMS default encryption. The destination bucket must use Amazon S3 managed keys (SSE-S3). If the destination bucket uses SSE-KMS, Amazon S3 might deliver log objects that are encrypted with a key that you can't access.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. In this case, you must update the bucket policy for the destination bucket to grant access to the logging service principal. You can't update your bucket ACL to grant access to the S3 log delivery group. You also can't include destination grants (also known as *target grants*) in your PutBucketLogging configuration.

For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see Grant access to the S3 log delivery group for server access logging. For more information about Object Ownership, see Controlling ownership of objects and disabling ACLs for your bucket. When you create new buckets, ACLs are disabled by default.

Granting access by using a bucket policy

To grant access by using the bucket policy on the destination bucket, update the bucket policy to grant the `s3:PutObject` permission to the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the bucket policy on the destination bucket to grant this permission to the logging service principal. If you enable server access logging programmatically, you must manually update the bucket policy for the destination bucket to grant access to the logging service principal.

For an example bucket policy that grants access to the logging service principal, see the section called “Grant permissions to the logging service principal by using a bucket policy”.

Granting access by using bucket ACLs

You can alternately use bucket ACLs to grant access for access log delivery. You add a grant entry to the bucket ACL that grants `WRITE` and `READ_ACP` permissions to the S3 log delivery group. However, granting access to the S3 log delivery group by using bucket ACLs is not recommended. For more information, see Controlling ownership of objects and disabling ACLs for your bucket. For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see Grant access to the S3 log delivery group for server access logging. For an example ACL that grants access to the logging service principal, see the section called “Grant permissions to the log delivery group by using a bucket ACL”.

Grant permissions to the logging service principal by using a bucket policy

This example bucket policy grants the `s3:PutObject` permission to the logging service principal (`logging.s3.amazonaws.com`). To use this bucket policy, replace the *`user`*

input placeholders with your own information. In the following policy, *amzn-s3-demo-destination-bucket* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-bucket* is the source bucket. *EXAMPLE-LOGGING-PREFIX* is the optional destination prefix (also known as a *target prefix*) that you want to use for your log objects. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

> **Note**
>
> If there are Deny statements in your bucket policy, make sure that they don't prevent Amazon S3 from delivering access logs.

JSON

```

        }
    ]
}
```

Grant permissions to the log delivery group by using a bucket ACL

> **Note**
>
> As a security best practice, Amazon S3 disables access control lists (ACLs) by default in all new buckets. For more information about ACL permissions in the Amazon S3 console, see Configuring ACLs.

Although we do not recommend this approach, you can grant permissions to the log delivery group by using a bucket ACL. However, if the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination grants (also known as *target grants*) in your PutBucketLogging configuration. Instead, you must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see Permissions for log delivery.

In the bucket ACL, the log delivery group is represented by the following URL:

```
http://acs.amazonaws.com/groups/s3/LogDelivery
```

To grant `WRITE` and `READ_ACP` (ACL read) permissions, add the following grants to the destination bucket ACL:

```
<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
    </Grantee>
    <Permission>WRITE</Permission>
</Grant>
<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
    </Grantee>
    <Permission>READ_ACP</Permission>
</Grant>
```

For examples of adding ACL grants programmatically, see Configuring ACLs.

Important

When you enable Amazon S3 server access logging by using AWS CloudFormation on a bucket and you're using ACLs to grant access to the S3 log delivery group, you must also add `"AccessControl": "LogDeliveryWrite"` to your CloudFormation template. Doing so is important because you can grant those permissions only by creating an ACL for the bucket, but you can't create custom ACLs for buckets in CloudFormation. You can use only canned ACLs with CloudFormation.

To enable server access logging

To enable server access logging by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, and AWS CLI, use the following procedures.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable server access logging for.
4. Choose **Properties**.
5. In the **Server access logging** section, choose **Edit**.
6. Under **Server access logging**, choose **Enable**.
7. Under **Destination bucket**, specify a bucket and an optional prefix. If you specify a prefix, we recommend including a forward slash (/) after the prefix to make it easier to find your logs.

Note

Specifying a prefix with a slash (/) makes it simpler for you to locate the log objects. For example, if you specify the prefix value `logs/`, each log object that Amazon S3 creates begins with the `logs/` prefix in its key, as follows:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value `logs`, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

8. Under **Log object key format**, do one of the following:

   - To choose non-date-based partitioning, choose **[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**.
   - To choose date-based partitioning, choose **[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**, then choose **S3 event time** or **Log file delivery time**.

9. Choose **Save changes**.

   When you enable server access logging on a bucket, the console both enables logging on the source bucket and updates the bucket policy for the destination bucket to grant the `s3:PutObject` permission to the logging service principal (`logging.s3.amazonaws.com`). For more information about this bucket policy, see Grant permissions to the logging service principal by using a bucket policy.

   You can view the logs in the destination bucket. After you enable server access logging, it might take a few hours before the logs are delivered to the target bucket.

For more information, see Viewing the properties for an S3 general purpose bucket.

Using the REST API

To enable logging, you submit a PutBucketLogging request to add the logging configuration on the source bucket. The request specifies the destination bucket (also known as a *target bucket*) and, optionally, the prefix to be used with all log object keys.

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket and *logs/* as the prefix.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>logs/</TargetPrefix>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket, *logs/* as the prefix, and `EventTime` as the log object key format.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>logs/</TargetPrefix>
    <TargetObjectKeyFormat>
      <PartitionedPrefix>
         <PartitionDateSource>EventTime</PartitionDateSource>
      </PartitionedPrefix>
  </TargetObjectKeyFormat>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The log objects are written and owned by the S3 log delivery account, and the bucket owner is granted full permissions on the log objects. You can optionally use destination grants (also known as *target grants*) to grant permissions to other users so that they can access the logs. For more information, see PutBucketLogging.

> **Note**
>
> If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't use destination grants to grant permissions to other users. To grant permissions to others, you can update the bucket policy on the destination bucket. For more information, see Permissions for log delivery.

To retrieve the logging configuration on a bucket, use the GetBucketLogging API operation.

To delete the logging configuration, you send a `PutBucketLogging` request with an empty `BucketLoggingStatus`:

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
</BucketLoggingStatus>
```

To enable logging on a bucket, you can use either the Amazon S3 API or the AWS SDK wrapper libraries.

Using the AWS SDKs

The following examples enable logging on a bucket. You must create two buckets, a source bucket and a destination (target) bucket. The examples update the bucket ACL on the destination bucket first. They then grant the log delivery group the necessary permissions to write logs to the destination bucket, and then they enable logging on the source bucket.

These examples won't work on destination buckets that use the Bucket owner enforced setting for Object Ownership.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your PutBucketLogging configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see Permissions for log delivery.

                .build());
    }

}
```

Using the AWS CLI

We recommend that you create a dedicated logging bucket in each AWS Region that you have S3 buckets in. Then have your Amazon S3 access logs delivered to that S3 bucket. For more information and examples, see put-bucket-logging in the *AWS CLI Reference*.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your PutBucketLogging configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see Permissions for log delivery.

Example— Enable access logs with five buckets across two Regions

In this example, you have the following five buckets:

- *amzn-s3-demo-source-bucket*-us-east-1
- *amzn-s3-demo-source-bucket1*-us-east-1
- *amzn-s3-demo-source-bucket2*-us-east-1
- *amzn-s3-demo-bucket1*-us-west-2
- *amzn-s3-demo-bucket2*-us-west-2

> **Note**
>
> The final step of the following procedure provides example bash scripts that you can use to create your logging buckets and enable server access logging on these buckets. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in the following procedure.

1. Create two logging destination buckets in the US West (Oregon) and US East (N. Virginia) Regions and give them the following names:
   - *amzn-s3-demo-destination-bucket*-logs-us-east-1
   - *amzn-s3-demo-destination-bucket1*-logs-us-west-2
2. Later in these steps, you will enable server access logging as follows:
   - *amzn-s3-demo-source-bucket*-us-east-1 logs to the S3 bucket *amzn-s3-demo-destination-bucket*-logs-us-east-1 with the prefix *amzn-s3-demo-source-bucket*-us-east-1
   - *amzn-s3-demo-source-bucket1*-us-east-1 logs to the S3 bucket *amzn-s3-demo-destination-bucket*-logs-us-east-1 with the prefix *amzn-s3-demo-source-bucket1*-us-east-1

- *amzn-s3-demo-source-bucket2*-us-east-1 logs to the S3 bucket *amzn-s3-demo-destination-bucket*-logs-us-east-1 with the prefix *amzn-s3-demo-source-bucket2*-us-east-1
- *amzn-s3-demo-bucket1*-us-west-2 logs to the S3 bucket *amzn-s3-demo-destination-bucket1*-logs-us-west-2 with the prefix *amzn-s3-demo-bucket1*-us-west-2
- *amzn-s3-demo-bucket2*-us-west-2 logs to the S3 bucket *amzn-s3-demo-destination-bucket1*-logs-us-west-2 with the prefix *amzn-s3-demo-bucket2*-us-west-2

3. For each destination logging bucket, grant permissions for server access log delivery by using a bucket ACL *or* a bucket policy:

   - **Update the bucket policy** (Recommended) – To grant permissions to the logging service principal, use the following `put-bucket-policy` command. Replace *amzn-s3-demo-destination-bucket*-logs with the name of your destination bucket.

     ```
     aws s3api put-bucket-policy --bucket amzn-s3-demo-destination-bucket-logs --
     policy file://policy.json
     ```

     `Policy.json` is a JSON document in the current folder that contains the following bucket policy. To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *amzn-s3-demo-destination-bucket-logs* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-bucket* is the source bucket. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

     JSON

     ```
     {
         "Version":"2012-10-17",
         "Statement": [
             {
                 "Sid": "S3ServerAccessLogsPolicy",
                 "Effect": "Allow",
                 "Principal": {
                     "Service": "logging.s3.amazonaws.com"
                 },
     ```

```
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket-logs/
*",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-
bucket"
                },
                "StringEquals": {
                    "aws:SourceAccount": "SOURCE-ACCOUNT-ID"
                }
            }
        }
    ]
}
```

- **Update the bucket ACL** – To grant permissions to the S3 log delivery group, use the following `put-bucket-acl` command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-destination-bucket-logs  --
grant-write URI=http://acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp
 URI=http://acs.amazonaws.com/groups/s3/LogDelivery
```

4. Then, create a `logging.json` file that contains your logging configuration (based on one of the three examples that follow). After you create the `logging.json` file, you can apply the logging configuration by using the following `put-bucket-logging` command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-logging --bucket amzn-s3-demo-destination-bucket-logs --
bucket-logging-status file://logging.json
```

> **Note**
>
> Instead of using this `put-bucket-logging` command to apply the logging configuration on each destination bucket, you can use one of the bash scripts provided in the next step. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in this procedure.

The `logging.json` file is a JSON document in the current folder that contains your logging configuration. If a destination bucket uses the Bucket owner enforced setting for Object Ownership, your logging configuration can't contain destination (target) grants. For more information, see Permissions for log delivery.

Example– logging.json without destination (target) grants

The following example `logging.json` file doesn't contain destination (target) grants. Therefore, you can apply this configuration to a destination (target) bucket that uses the Bucket owner enforced setting for Object Ownership.

```
{
    "LoggingEnabled": {
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",
        "TargetPrefix": "amzn-s3-demo-destination-bucket/"
     }
 }
```

Example– logging.json with destination (target) grants

The following example `logging.json` file contains destination (target) grants.

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't include destination (target) grants in your PutBucketLogging configuration. For more information, see Permissions for log delivery.

```
{
    "LoggingEnabled": {
```

```
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",
        "TargetGrants": [
             {
                "Grantee": {
                    "Type": "CanonicalUser",
                    "ID":
"79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be"
                 },
                "Permission": "FULL_CONTROL"
             }
         ]
     }
  }
```

Grantee values

You can specify the person (grantee) to whom you're assigning access rights (by using request elements) in the following ways:

- By the person's ID:

```
{
  "Grantee": {
    "Type": "CanonicalUser",
    "ID": "ID"
  }
}
```

- By URI:

```
{
  "Grantee": {
    "Type": "Group",
    "URI": "http://acs.amazonaws.com/groups/global/AuthenticatedUsers"
  }
}
```

Example– logging.json with the log object key format set to S3 event time

The following `logging.json` file changes the log object key format to S3 event time.

```
  {
    "LoggingEnabled": {
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",
        "TargetObjectKeyFormat": {
            "PartitionedPrefix": {
                "PartitionDateSource": "EventTime"
            }
         }
    }
}
```

5. Use one of the following bash scripts to add access logging for all the buckets in your account. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket, and replace *us-west-2* with the name of the Region that your buckets are located in.

> **Note**
>
> This script works only if all of your buckets are in the same Region. If you have buckets in multiple Regions, you must adjust the script.

Example– Grant access with bucket policies and add logging for the buckets in your account

```
loggingBucket='amzn-s3-demo-destination-bucket-logs'
region='us-west-2'

# Create the logging bucket.
aws s3 mb s3://$loggingBucket --region $region

aws s3api put-bucket-policy --bucket $loggingBucket --policy file://policy.json
```

```
  # List the buckets in this account.
  buckets="$(aws s3 ls | awk '{print $3}')"

  # Put a bucket logging configuration on each bucket.
  for bucket in $buckets
      do
        # This if statement excludes the logging bucket.
        if [ "$bucket" == "$loggingBucket" ] ; then
            continue;
        fi
        printf '{
          "LoggingEnabled": {
            "TargetBucket": "%s",
            "TargetPrefix": "%s/"
        }
      }' "$loggingBucket" "$bucket"  > logging.json
      aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
      echo "$bucket done"
  done

  rm logging.json

  echo "Complete"
```

Example– Grant access with bucket ACLs and add logging for the buckets in your account

```
  loggingBucket='amzn-s3-demo-destination-bucket-logs'
  region='us-west-2'

  # Create the logging bucket.
  aws s3 mb s3://$loggingBucket --region $region

  aws s3api put-bucket-acl --bucket $loggingBucket --grant-write URI=http://
acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp URI=http://
acs.amazonaws.com/groups/s3/LogDelivery

  # List the buckets in this account.
  buckets="$(aws s3 ls | awk '{print $3}')"
```

```
  # Put a bucket logging configuration on each bucket.
  for bucket in $buckets
      do
        # This if statement excludes the logging bucket.
        if [ "$bucket" == "$loggingBucket" ] ; then
            continue;
        fi
        printf '{
          "LoggingEnabled": {
            "TargetBucket": "%s",
            "TargetPrefix": "%s/"
        }
      }' "$loggingBucket" "$bucket"  > logging.json
      aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
      echo "$bucket done"
  done

  rm logging.json

  echo "Complete"
```

Verifying your server access logs setup

After you enable server access logging, complete the following steps:

- Access the destination bucket and verify that the log files are being delivered. After the access logs are set up, Amazon S3 immediately starts capturing requests and logging them. However, it might take a few hours before the logs are delivered to the destination bucket. For more information, see the section called “Bucket logging status changes take effect over time” and the section called “Best-effort server log delivery”.

  You can also automatically verify log delivery by using Amazon S3 request metrics and setting up Amazon CloudWatch alarms for these metrics. For more information, see Monitoring metrics with Amazon CloudWatch.
- Verify that you are able to open and read the contents of the log files.

For server access logging troubleshooting information, see Troubleshoot server access logging.

Amazon S3 server access log format

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. You can use server access logs for the following purposes:

- Performing security and access audits
- Learning about your customer base
- Understanding your Amazon S3 bill

This section describes the format and other details about Amazon S3 server access log files.

> **Note**
>
> This page covers the space-delimited text format used for logs delivered to an Amazon S3 general purpose bucket. For the structured JSON format used in Amazon CloudWatch Logs, see Log format in CloudWatch Logs.

Server access log files consist of a sequence of newline-delimited log records. Each log record represents one request and consists of space-delimited fields.

The following is an example log consisting of five log records.

> **Note**
>
> Any field can be set to `-` to indicate that the data was unknown or unavailable, or that the field was not applicable to this request.

```

Topics

- Log record fields
- Additional logging for copy operations
- Custom access log information
- Programming considerations for extensible server access log format

Log record fields

The following list describes the log record fields.

Bucket Owner

The canonical user ID of the owner of the source bucket. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see AWS account identifiers in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see Finding the canonical user ID for your AWS account.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that the request was processed against. If the system receives a malformed request and cannot determine the bucket, the request will not appear in any server access log.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: `[%d/%b/%Y:%H:%M:%S %z]`

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a `-` for unauthenticated requests. If the requester was an IAM user, this field returns the requester's IAM user name along with the AWS account that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request. For **Compute checksum** job requests, the **Request ID** field displays the associated job ID. For more information, see Compute checksums.

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as `SOAP.`*`operation`*, `REST.`*`HTTP_method`*`.`*`resource_type`*, `WEBSITE.`*`HTTP_method`*`.`*`resource_type`*, or `BATCH.DELETE.OBJECT`, or `S3.action.resource_type` for S3 Lifecycle and logging. For Compute checksum job requests, the operation is listed as `S3.COMPUTE.OBJECT.CHECKSUM`.

Example entry

```
REST.PUT.OBJECT
```

```
S3.COMPUTE.OBJECT.CHECKSUM
```

Key

The key (object name) part of the request.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The `Request-URI` part of the HTTP request message. This field may include unescaped quotes from the user input.

Example Entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar HTTP/1.1"
```

HTTP status

The numeric HTTP status code of the response.

Example entry

```
200
```

Error Code

The Amazon S3 Error responses , or `-` if no error occurred.

Example entry

```
NoSuchBucket
```

Bytes Sent

The number of response bytes sent, excluding HTTP protocol overhead, or `-` if zero.

Example entry

```
2662992
```

Object Size

The total size of the object in question.

Example entry

```
3462992
```

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

```
70
```

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

```
10
```

Referer

The value of the HTTP `Referer` header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request. This field may include unescaped quotes from the user input.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP `User-Agent` header. This field may include unescaped quotes from the user input.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID in the request, or `-` if the operation doesn't take a `versionId` parameter.

Example entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s9lzHYrFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request or a `-` for unauthenticated requests.

Example entry

```
SigV2
```

Cipher Suite

The Transport Layer Security (TLS) cipher that was negotiated for an HTTPS request or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query string (presigned URL), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see Legacy endpoints. For a complete list of Amazon S3 Regions and endpoints, see Amazon S3 endpoints and quotas in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: `TLSv1.1`, `TLSv1.2`, `TLSv1.3`, or `-` if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a `-`. For more information about access points, see Using Amazon S3 access points for general purpose buckets. For more information about ARNs, see Amazon Resource Name (ARN) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is `Yes`. If no ACLs were required, the string is `-`. For more information about ACLs, see Access control list (ACL) overview. For more information about using the `aclRequired` field to disable ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

Example entry

```
Yes
```

Source region

The AWS Region from which the request originated. This field shows a dash (-) when the origin region cannot be determined (such as PrivateLink connections, Direct Connect connections, Bring your own IP addresses (BYOIP), or non-AWS IP addresses) or when the log is generated by operations triggered based on customer-set policies or actions, such as lifecycle and checksum.

Example entry

```
us-east-1
```

Additional logging for copy operations

A copy operation involves a `GET` and a `PUT`. For that reason, we log two records when performing a copy operation. The previous section describes the fields related to the `PUT` part of the operation. The following list describes the fields in the record that relate to the `GET` part of the copy operation.

Bucket Owner

The canonical user ID of the bucket that stores the object being copied. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see AWS account identifiers in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see Finding the canonical user ID for your AWS account.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that stores the object that's being copied.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: `[%d/%B/%Y:%H:%M:%S %z]`

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a `-` for unauthenticated requests. If the requester was an IAM user, this field will return the requester's IAM user name along with the AWS account root user that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request. For **Compute checksum** job requests, the **Request ID** field displays the associated job ID. For more information, see Compute checksums.

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as `SOAP.operation`, `REST.HTTP_method.resource_type`, `WEBSITE.HTTP_method.resource_type`, or `BATCH.DELETE.OBJECT`.

Example entry

```
REST.COPY.OBJECT_GET
```

Key

The key (object name) of the object being copied, or `-` if the operation doesn't take a key parameter.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The `Request-URI` part of the HTTP request message. This field may include unescaped quotes from the user input.

Example entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar"
```

HTTP status

The numeric HTTP status code of the GET portion of the copy operation.

Example entry

```
200
```

Error Code

The Amazon S3 Error responses of the GET portion of the copy operation, or - if no error occurred.

Example entry

```
NoSuchBucket
```

Bytes Sent

The number of response bytes sent, excluding the HTTP protocol overhead, or - if zero.

Example entry

```
2662992
```

Object Size

The total size of the object in question.

Example entry

```
3462992
```

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

```
70
```

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

```
10
```

Referer

The value of the HTTP `Referer` header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request. This field may include unescaped quotes from the user input.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP `User-Agent` header. This field may include unescaped quotes from the user input.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID of the object being copied, or `-` if the `x-amz-copy-source` header didn't specify a `versionId` parameter as part of the copy source.

Example Entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s9lzHYrFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request, or a `-` for unauthenticated requests.

Example entry

```
SigV4
```

Cipher Suite

The Transport Layer Security (TLS) cipher that was negotiated for an HTTPS request, or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query strings (presigned URLs), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint that was used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see Legacy endpoints. For a complete list of Amazon S3 Regions and endpoints, see Amazon S3 endpoints and quotas in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: `TLSv1.1`, `TLSv1.2`, `TLSv1.3`, or `-` if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a `-`. For more information about access points, see Using Amazon S3 access points for general purpose buckets. For more information about ARNs, see Amazon Resource Name (ARN) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is `Yes`. If no ACLs were required, the string is `-`. For more information about ACLs, see Access control list (ACL) overview. For more information about using the `aclRequired` field to disable ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

Example entry

```
Yes
```

Source region

The AWS Region from which the request originated. This field shows a dash (-) when the origin region cannot be determined (such as PrivateLink connections, Direct Connect connections,

Bring your own IP addresses (BYOIP), or non-AWS IP addresses) or when the log is generated by operations triggered based on customer-set policies or actions, such as lifecycle and checksum.

Example entry

```
us-east-1
```

Custom access log information

You can include custom information to be stored in the access log record for a request. To do this, add a custom query-string parameter to the URL for the request. Amazon S3 ignores query-string parameters that begin with `x-`, but includes those parameters in the access log record for the request, as part of the `Request-URI` field of the log record.

For example, a `GET` request for `"s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-user=johndoe"` works the same as the request for `"s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg"`, except that the `"x-user=johndoe"` string is included in the `Request-URI` field for the associated log record. This functionality is available in the REST interface only.

Programming considerations for extensible server access log format

Occasionally, we might extend the access log record format by adding new fields to the end of each line. Therefore, make sure that any of your code that parses server access logs can handle trailing fields that it might not understand.

Managing log retention

An Amazon S3 bucket with server access logging enabled can accumulate many server log objects over time. You can use Amazon S3 Lifecycle configuration to set rules so that Amazon S3 automatically deletes log objects after a specified period. If you specified a prefix in your logging configuration, you can scope the lifecycle rule to that prefix. For example, if your log objects have the prefix `logs/`, you can create a lifecycle rule to delete all objects with that prefix after a specified number of days. For more information, see Managing the lifecycle of objects.

For logs delivered to CloudWatch Logs, see Managing log retention.

Using Amazon S3 server access logs to identify requests

You can identify Amazon S3 requests by using Amazon S3 server access logs.

Note

- To identify Amazon S3 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information. For more information, see Identifying Amazon S3 requests using CloudTrail.
- Depending on how many access requests you get, analyzing your logs might require more resources or time than using CloudTrail data events.

Topics

- Querying access logs for requests by using Amazon Athena
- Identifying Signature Version 2 requests
- Identifying object access requests

Querying access logs for requests by using Amazon Athena

You can identify Amazon S3 requests with Amazon S3 access logs by using Amazon Athena.

Amazon S3 stores server access logs as objects in an S3 bucket. It is often easier to use a tool that can analyze the logs in Amazon S3. Athena supports analysis of S3 objects and can be used to query Amazon S3 access logs.

Example

The following example shows how you can query Amazon S3 server access logs in Amazon Athena. Replace the *`user input placeholders`* used in the following examples with your own information.

Note

To specify an Amazon S3 location in an Athena query, you must provide an S3 URI for the bucket where your logs are delivered to. This URI must include the bucket name and prefix in the following format: `s3://`*`amzn-s3-demo-bucket1-logs/prefix`*`/`

1. Open the Athena console at https://console.aws.amazon.com/athena/.

2. In the Query Editor, run a command similar to the following. Replace *s3_access_logs_db* with the name that you want to give to your database.

```
CREATE DATABASE s3_access_logs_db
```

> **Note**
>
> It's a best practice to create the database in the same AWS Region as your S3 bucket.

3. In the Query Editor, run a command similar to the following to create a table schema in the database that you created in step 2. Replace *s3_access_logs_db.mybucket_logs* with the name that you want to give to your table. The `STRING` and `BIGINT` data type values are the access log properties. You can query these properties in Athena. For `LOCATION`, enter the S3 bucket and prefix path as noted earlier.

   Date-based partitioning

```
CREATE EXTERNAL TABLE s3_access_logs_db.mybucket_logs(
 `bucketowner` STRING,
 `bucket_name` STRING,
 `requestdatetime` STRING,
 `remoteip` STRING,
 `requester` STRING,
 `requestid` STRING,
 `operation` STRING,
 `key` STRING,
 `request_uri` STRING,
 `httpstatus` STRING,
 `errorcode` STRING,
 `bytessent` BIGINT,
 `objectsize` BIGINT,
 `totaltime` STRING,
 `turnaroundtime` STRING,
 `referrer` STRING,
 `useragent` STRING,
 `versionid` STRING,
 `hostid` STRING,
 `sigv` STRING,
 `ciphersuite` STRING,
 `authtype` STRING,
 `endpoint` STRING,
```

```
 `tlsversion` STRING,
 `accesspointarn` STRING,
 `aclrequired` STRING,
 `sourceregion` STRING)
 PARTITIONED BY (
   `timestamp` string)
ROW FORMAT SERDE
 'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
 'input.regex'='([^ ]*) ([^ ]*) \\[(.*?)\\] ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) (-|[0-9]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) ([^ ]*)(?: ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*))?.*$')

  'projection.timestamp.type'='date',
  'storage.location.template'='s3://bucket-name/prefix-name/account-id/region/
source-bucket-name/${timestamp}')
```

Non-date-based partitioning

```
CREATE EXTERNAL TABLE `s3_access_logs_db.mybucket_logs`(
  `bucketowner` STRING,
  `bucket_name` STRING,
  `requestdatetime` STRING,
  `remoteip` STRING,
  `requester` STRING,
  `requestid` STRING,
  `operation` STRING,
  `key` STRING,
  `request_uri` STRING,
  `httpstatus` STRING,
  `errorcode` STRING,
```

```
  `bytessent` BIGINT,
  `objectsize` BIGINT,
  `totaltime` STRING,
  `turnaroundtime` STRING,
  `referrer` STRING,
  `useragent` STRING,
  `versionid` STRING,
  `hostid` STRING,
  `sigv` STRING,
  `ciphersuite` STRING,
  `authtype` STRING,
  `endpoint` STRING,
  `tlsversion` STRING,
  `accesspointarn` STRING,
  `aclrequired` STRING,
  `sourceregion` STRING)
ROW FORMAT SERDE
  'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
  'input.regex'='([^ ]*) ([^ ]*) \\[(.*?)\\] ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) (-|[0-9]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) ([^ ]*)(?: ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*))?.*$')
STORED AS INPUTFORMAT
  'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
  'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
  's3://amzn-s3-demo-bucket1-logs/prefix/'
```

4. In the navigation pane, under **Database**, choose your database.
5. Under **Tables**, choose **Preview table** next to your table name.

   In the **Results** pane, you should see data from the server access logs, such as `bucketowner`, `bucket`, `requestdatetime`, and so on. This means that you successfully created the Athena table. You can now query the Amazon S3 server access logs.

Example— Show who deleted an object and when (timestamp, IP address, and IAM user)

```
SELECT requestdatetime, remoteip, requester, key
FROM s3_access_logs_db.mybucket_logs
WHERE key = 'images/picture.jpg' AND operation like '%DELETE%';
```

Example— Show all operations that were performed by an IAM user

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE requester='arn:aws:iam::123456789123:user/user_name';
```

Example— Show all operations that were performed on an object in a specific time period

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE Key='prefix/images/picture.jpg'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2017-02-18:07:00:00','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2017-02-18:08:00:00','yyyy-MM-dd:HH:mm:ss');
```

Example— Show how much data was transferred to a specific IP address in a specific time period

```
SELECT coalesce(SUM(bytessent), 0) AS bytessenttotal
FROM s3_access_logs_db.mybucket_logs
WHERE remoteip='192.0.2.1'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-06-01','yyyy-MM-dd')
AND parse_datetime('2022-07-01','yyyy-MM-dd');
```

Example— Find request IDs for HTTP 5xx errors in a specific time period

```
SELECT requestdatetime, key, httpstatus, errorcode, requestid, hostid
FROM s3_access_logs_db.mybucket_logs
WHERE httpstatus like '5%' AND timestamp
BETWEEN '2024/01/29'
AND '2024/01/30'
```

Identifying Signature Version 2 requests

You can use server access logs to identify Signature Version 2 requests. For details on querying logs with Amazon Athena, see the Athena querying section under Delivering logs to an Amazon S3 general purpose bucket.

Identifying object access requests

You can use server access logs to identify object access patterns. For details on querying logs with Amazon Athena, see the Athena querying section under Delivering logs to an Amazon S3 general purpose bucket.

Troubleshoot server access logging

The following topics can help you troubleshoot issues that you might encounter when setting up logging with Amazon S3.

Topics

- Common error messages when setting up logging
- Troubleshooting delivery failures

Common error messages when setting up logging

The following common error messages can appear when you're enabling logging through the AWS Command Line Interface (AWS CLI) and AWS SDKs:

Error: Cross S3 location logging not allowed

If the destination bucket (also known as a *target bucket*) is in a different Region than the source bucket, a Cross S3 location logging not allowed error occurs. To resolve this error, make sure that the destination bucket configured to receive the access logs is in the same AWS Region and AWS account as the source bucket.

Error: The owner for the bucket to be logged and the target bucket must be the same

When you're enabling server access logging, this error occurs if the specified destination bucket belongs to a different account. To resolve this error, make sure that the destination bucket is in the same AWS account as the source bucket.

> **Note**
>
> We recommend that you choose a destination bucket that's different from the source bucket. When the source bucket and destination bucket are the same, additional logs are created for the logs that are written to the bucket, which can increase your storage bill. These extra logs about logs can also make it difficult to find the particular logs that you're

looking for. For simpler log management, we recommend saving access logs in a different bucket.

Error: The target bucket for logging does not exist

The destination bucket must exist prior to setting the configuration. This error indicates that the destination bucket doesn't exist or can't be found. Make sure that the bucket name is spelled correctly, and then try again.

Error: Target grants not allowed for bucket owner enforced buckets

This error indicates that the destination bucket uses the Bucket owner enforced setting for S3 Object Ownership. The Bucket owner enforced setting doesn't support destination (target) grants. For more information, see Permissions for log delivery.

Troubleshooting delivery failures

To avoid server access logging issues, make sure that you're following these best practices:

- **The S3 log delivery group has write access to the destination bucket** – The S3 log delivery group delivers server access logs to the destination bucket. A bucket policy or bucket access control list (ACL) can be used to grant write access to the destination bucket. However, we recommend that you use a bucket policy instead of an ACL. For more information about how to grant write access to your destination bucket, see Permissions for log delivery.

  Note

  If the destination bucket uses the Bucket owner enforced setting for Object Ownership, be aware of the following:

  - ACLs are disabled and no longer affect permissions. This means that you can't update your bucket ACL to grant access to the S3 log delivery group. Instead, to grant access to the logging service principal, you must update the bucket policy for the destination bucket.
  - You can't include destination grants in your `PutBucketLogging` configuration.

- **The bucket policy for the destination bucket allows access to the logs** – Check the bucket policy of the destination bucket. Search the bucket policy for any statements that contain

`"Effect": "Deny"`. Then, verify that the `Deny` statement isn't preventing access logs from being written to the bucket.

- **S3 Object Lock isn't enabled on the destination bucket** – Check if the destination bucket has Object Lock enabled. Object Lock blocks server access log delivery. You must choose a destination bucket that doesn't have Object Lock enabled.
- **The destination bucket must use Amazon S3 managed keys (SSE-S3)** – If the destination bucket uses SSE-KMS default encryption, log objects might be created but encrypted with a key that you can't access.
- **The destination bucket does not have Requester Pays enabled** – Using a Requester Pays bucket as the destination bucket for server access logging is not supported. To allow delivery of server access logs, disable the Requester Pays option on the destination bucket.
- **Review your AWS Organizations service control policies (SCPs) and resource control policies (RCPs)** – When you're using AWS Organizations, check the service control policies and resource control policies to make sure that Amazon S3 access is allowed. These policies specify the maximum permissions for principals and resources in the affected accounts. Search the policies for any statements that contain `"Effect": "Deny"` and verify that `Deny` statements aren't preventing any access logs from being written to the bucket. For more information, see Authorization policies in AWS Organizations in the *AWS Organizations User Guide*.
- **Allow some time for recent logging configuration changes to take effect** – Enabling server access logging for the first time, or changing the destination bucket for logs, requires time to fully take effect. It might take longer than an hour for all requests to be properly logged and delivered.

  To check for log delivery failures, enable request metrics in Amazon CloudWatch. If the logs are not delivered within a few hours, look for the `4xxErrors` metric, which can indicate log delivery failures. For more information about enabling request metrics, see the section called “Creating a metrics configuration for all objects”.

Monitoring metrics with Amazon CloudWatch

Amazon CloudWatch metrics for Amazon S3 can help you understand and improve the performance of applications that use Amazon S3. There are several ways that you can use CloudWatch with Amazon S3.

Daily storage metrics for buckets

Monitor bucket storage using CloudWatch, which collects and processes storage data from Amazon S3 into readable, daily metrics. These storage metrics for Amazon S3 are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor Amazon S3 requests to quickly identify and act on operational issues. The metrics are available at 1-minute intervals after some latency for processing. These CloudWatch metrics are billed at the same rate as the Amazon CloudWatch custom metrics. For information about CloudWatch pricing, see Amazon CloudWatch pricing. To learn how to opt in to getting these metrics, see CloudWatch metrics configurations.

When enabled, request metrics are reported for all object operations. By default, these 1-minute metrics are available at the Amazon S3 bucket level. You can also define a filter for the metrics using a shared prefix, object tag, or access point:

- **Access point** – Access points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. With the access point filter, you can gain insights into your access point usage. For more information about access points, see Monitoring and logging access points.
- **Prefix** – Although the Amazon S3 data model is a flat structure, you can use prefixes to infer a hierarchy. A prefix is similar to a directory name that enables you to group similar objects together in a bucket. The S3 console supports prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see Organizing objects using prefixes.
- **Tags** – Tags are key-value name pairs that you can add to objects. Tags help you find and organize objects easily. You can also use tags as a filter for metrics configurations so that only objects with those tags are included in the metrics configuration. For more information about object tags, see Tagging your objects.

To align these metrics to specific business applications, workflows, or internal organizations, you can filter on a shared prefix, object tag, or access point.

Replication metrics

Monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination AWS Region, and the total number of operations that failed replication. Replication rules that have S3 Replication Time Control (S3 RTC) or S3 Replication metrics enabled will publish replication metrics.

For more information, see Monitoring replication with metrics, event notifications, and statuses or Meeting compliance requirements with S3 Replication Time Control.

Amazon S3 Storage Lens metrics

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. S3 Storage Lens metrics are available in the `AWS/S3/Storage-Lens` namespace. The CloudWatch publishing option is available for S3 Storage Lens dashboards upgraded to *advanced metrics and recommendations*. You can enable the CloudWatch publishing option for a new or existing dashboard configuration in S3 Storage Lens.

For more information, see Monitor S3 Storage Lens metrics in CloudWatch.

All CloudWatch statistics are retained for a period of 15 months so that you can access historical information and gain a better perspective on how your web application or service is performing. For more information about CloudWatch, see What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*. You may need some additional configurations to your CloudWatch alarms, depending on your use cases. For example, you can use metric math expression to create an alarm. For more information, see Use CloudWatch metrics, Use metric math, Using Amazon CloudWatch alarms, and Create a CloudWatch alarm based on a metric math expression in the *Amazon CloudWatch User Guide*.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

For more information, see the following topics.

Topics

- Metrics and dimensions
- Accessing CloudWatch metrics
- CloudWatch metrics configurations

Metrics and dimensions

The storage metrics and dimensions that Amazon S3 sends to Amazon CloudWatch are listed in the following tables.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

Amazon S3 daily storage metrics for buckets in CloudWatch

The AWS/S3 namespace includes the following daily storage metrics for buckets.

Metric	Description
BucketSizeBytes	The amount of data in bytes that is stored in a bucket in the following storage classes: • Reduced Redundancy Storage (RRS) (REDUCED_REDUNDANCY) • S3 Express One Zone (EXPRESS_ONEZONE) • S3 Glacier Deep Archive (DEEP_ARCHIVE) • S3 Glacier Flexible Retrieval (GLACIER) • S3 Glacier Instant Retrieval (GLACIER_IR) • S3 Intelligent-Tiering (INTELLIGENT_TIERING) • S3 One Zone-Infrequent Access (ONEZONE_IA) • S3 Standard (STANDARD) • S3 Standard-Infrequent Access (STANDARD_IA) This value is calculated by summing the size of all objects and metadata (such as bucket names) in the bucket (both current and noncurrent objects), including the size of all parts for all incomplete multipart uploads to the bucket. **Note** The S3 Express One Zone storage class is available only for directory buckets. Valid storage-type filters (see the StorageType dimension): • Reduced Redundancy Storage (RRS): ReducedRedundancyStorage

Metric	Description
	• S3 Express One Zone: `ExpressOneZoneStorage` • S3 Glacier Deep Archive: `DeepArchiveObjectOverhead` , `DeepArchiveS3ObjectOverhead` , `DeepArchiveStagingStorage` , `DeepArchiveStorage` • S3 Glacier Flexible Retrieval: `GlacierObjectOverhead` , `GlacierS3ObjectOverhead` , `GlacierStagingStorage` , `GlacierStorage` • S3 Glacier Instant Retrieval: `GlacierInstantRetrievalStorage` , `GlacierIRSizeOverhead` • S3 Intelligent-Tiering: `IntelligentTieringAAStorage` , `IntelligentTieringAIAStorage` , `IntelligentTieringDAAStorage` , `IntelligentTieringFAStorage` , `IntelligentTieringIAStorage` • S3 One Zone-Infrequent Access: `OneZoneIASizeOverhead` , `OneZoneIAStorage` • S3 Standard: `StandardStorage` • S3 Standard-Infrequent Access: `StandardIAObjectOverhead` , `StandardIASizeOverhead` , `StandardIAStorage` Units: Bytes Valid statistics: Average For more information about the `StorageType` dimensions, see the section called “Amazon S3 dimensions in CloudWatch”.

Metric	Description
NumberOfObjects	The total number of objects stored in a general purpose bucket for all storage classes. This value is calculated by counting all objects in the bucket, which includes current and noncurrent objects, delete markers, and the total number of parts for all incomplete multipart uploads to the bucket. For directory buckets with objects in the S3 Express One Zone storage class, this value is calculated by counting all objects in the bucket, but it doesn't include incomplete multipart uploads to the bucket. Valid storage type filters: AllStorageTypes (see the StorageType dimension) Units: Count Valid statistics: Average

Amazon S3 request metrics in CloudWatch

The AWS/S3 namespace includes the following request metrics. These metrics include non-billable requests (in the case of GET requests from CopyObject and Replication).

Metric	Description
AllRequests	The total number of HTTP requests made to an Amazon S3 bucket, regardless of type. If you're using a metrics configuration with a filter, then this metric returns only the HTTP requests that meet the filter's requirements. Units: Count Valid statistics: Sum
GetRequests	The number of HTTP GET requests made for objects in an Amazon S3 bucket. This doesn't include list operations. This metric is incremented for the source of each CopyObject request.

Metric	Description
	Units: Count Valid statistics: Sum **Note** Paginated list-oriented requests, such as ListMultipartUploads, ListParts, ListObjectVersions, and others, are not included in this metric.
`PutRequests`	The number of HTTP `PUT` requests made for objects in an Amazon S3 bucket. This metric is incremented for the destination of each `CopyObject` request. Units: Count Valid statistics: Sum
`DeleteRequests`	The number of HTTP `DELETE` requests made for objects in an Amazon S3 bucket. This metric also includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted. Units: Count Valid statistics: Sum
`HeadRequests`	The number of HTTP `HEAD` requests made to an Amazon S3 bucket. Units: Count Valid statistics: Sum

Metric	Description
PostRequests	The number of HTTP POST requests made to an Amazon S3 bucket. Units: Count Valid statistics: Sum **Note** DeleteObjects and SelectObjectContent requests are not included in this metric.
SelectRequests	The number of Amazon S3 SelectObjectContent requests made for objects in an Amazon S3 bucket. Units: Count Valid statistics: Sum
SelectBytesScanned	The number of bytes of data scanned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9
SelectBytesReturned	The number of bytes of data returned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9

Metric	Description
`ListRequests`	The number of HTTP requests that list the contents of a bucket. Units: Count Valid statistics: Sum
`BytesDownloaded`	The number of bytes downloaded for requests made to an Amazon S3 bucket, where the response includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9
`BytesUploaded`	The number of bytes uploaded for requests made to an Amazon S3 bucket, where the request includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9
`4xxErrors`	The number of HTTP 4*xx* client error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count

Metric	Description
`5xxErrors`	The number of HTTP 5*xx* server error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
`FirstByteLatency`	The per-request time from the complete request being received by an Amazon S3 bucket to when the response starts to be returned. Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100
`TotalRequestLatency`	The elapsed per-request time from the first byte received to the last byte sent to an Amazon S3 bucket. This metric includes the time taken to receive the request body and send the response body, which is not included in `FirstByteLatency` . Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100

S3 Replication metrics in CloudWatch

You can monitor the progress of replication with S3 Replication metrics by tracking bytes pending, operations pending, and replication latency. For more information, see Monitoring progress with replication metrics.

Note

You can enable alarms for your replication metrics in Amazon CloudWatch. When you set up alarms for your replication metrics, set the **Missing data treatment** field to **Treat missing data as ignore (maintain the alarm state)**.

Metric	Description
`ReplicationLatency`	The maximum number of seconds by which the replication destination AWS Region is behind the source AWS Region for a given replication rule. Units: Seconds Valid statistics: Max
`BytesPendingReplication`	The total number of bytes of objects pending replication for a given replication rule. Units: Bytes Valid statistics: Max
`OperationsPendingReplication`	The number of operations pending replication for a given replication rule. Units: Count Valid statistics: Max
`OperationsFailedReplication`	The number of operations that failed to replicate for a given replication rule. Units: Count Valid statistics: Sum (total number of failed operations), Average (failure rate), Sample Count (total number of replication operations)

S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. S3 Storage Lens metrics are published to the `AWS/S3/Storage-Lens` namespace in CloudWatch. The CloudWatch publishing option is available for S3 Storage Lens dashboards that have been upgraded to advanced metrics and recommendations.

For a list of S3 Storage Lens metrics that are published to CloudWatch, see Amazon S3 Storage Lens metrics glossary. For a complete list of dimensions, see Dimensions.

S3 Object Lambda request metrics in CloudWatch

S3 Object Lambda includes the following request metrics.

Metric	Description
`AllRequests`	The total number of HTTP requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`GetRequests`	The number of HTTP `GET` requests made for objects by using an Object Lambda Access Point. This metric does not include list operations. Units: Count Valid statistics: Sum
`BytesUploaded`	The number of bytes uploaded to an Amazon S3 bucket by using an Object Lambda Access Point, where the request includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9

Metric	Description
`PostRequests`	The number of HTTP `POST` requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`PutRequests`	The number of HTTP `PUT` requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`DeleteRequests`	The number of HTTP `DELETE` requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. This metric includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted. Units: Count Valid statistics: Sum
`BytesDownloaded`	The number of bytes downloaded for requests made to an Amazon S3 bucket by using an Object Lambda Access Point, where the response includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9

Metric	Description
`FirstByteLatency`	The per-request time from the complete request being received by an Amazon S3 bucket through an Object Lambda Access Point to when the response starts to be returned. This metric is dependent on the AWS Lambda function's running time to transform the object before the function returns the bytes to the Object Lambda Access Point. Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100
`TotalRequestLatency`	The elapsed per-request time from the first byte received to the last byte sent to an Object Lambda Access Point. This metric includes the time taken to receive the request body and send the response body, which is not included in `FirstByteLatency` . Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100
`HeadRequests`	The number of HTTP `HEAD` requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`ListRequests`	The number of HTTP `GET` requests that list the contents of an Amazon S3 bucket. This metric includes both `ListObjects` and `ListObjectsV2` operations. Units: Count Valid statistics: Sum

Metric	Description
4xxErrors	The number of HTTP 4*xx* client error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
5xxErrors	The number of HTTP 5*xx* server error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
ProxiedRequests	The number of HTTP requests to an Object Lambda Access Point that return the standard Amazon S3 API response. (Such requests do not have a Lambda function configured.) Units: Count Valid statistics: Sum
InvokedLambda	The number of HTTP requests to an S3 object where a Lambda function was invoked. Units: Count Valid statistics: Sum

Metric	Description
LambdaResponseRequests	The number of WriteGetObjectResponse requests made by the Lambda function. This metric applies only to GetObject requests.
LambdaResponse4xx	The number of HTTP 4*xx* client errors that occur when calling WriteGetObjectResponse from a Lambda function. This metric provides the same information as 4xxErrors, but only for WriteGetObjectResponse calls.
LambdaResponse5xx	The number of HTTP 5*xx* server errors that occur when calling WriteGetObjectResponse from a Lambda function. This metric provides the same information as 5xxErrors, but only for WriteGetObjectResponse calls.

Amazon S3 dimensions in CloudWatch

The following dimensions are used to filter Amazon S3 metrics.

Dimension	Description
BucketName	This dimension filters the data that you request for the identified bucket only.
StorageType	This dimension filters the data that you have stored in a bucket by the following types of storage: • DeepArchiveObjectOverhead – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive rates for this additional storage. • DeepArchiveS3ObjectOverhead – For each object archived to S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage.

Dimension	Description
	• `DeepArchiveStagingStorage` – The number of bytes used for parts of multipart upload objects before the `CompleteMultipartUpload` request is completed on objects in the S3 Glacier Deep Archive storage class. • `DeepArchiveStorage` – The number of bytes used for objects in the S3 Glacier Deep Archive storage class. • `ExpressOneZoneStorage` – The number of bytes used for objects in the S3 Express One Zone storage class. • `GlacierInstantRetrievalStorage` – The number of bytes used for objects in the S3 Glacier Instant Retrieval storage class. • `GlacierIRSizeOverhead` – For objects smaller than 128 KB stored in the S3 Glacier Instant Retrieval storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • `GlacierObjectOverhead` – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage. • `GlacierS3ObjectOverhead` – For each object archived to S3 Glacier Flexible Retrieval, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • `GlacierStagingStorage` – The number of bytes used for parts of multipart upload objects before the `CompleteMultipartUpload` request is completed on objects in the S3 Glacier Flexible Retrieval storage class. • `GlacierStorage` – The number of bytes used for objects in the S3 Glacier Flexible Retrieval storage class. • `IntAAObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Archive Access tier, S3 Glacier adds 32 KB of storage for index and

Dimension	Description
	related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage. • `IntAAS3ObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Archive Access tier, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • `IntDAAObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Deep Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive storage rates for this additional storage. • `IntDAAS3ObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Deep Archive Access tier, Amazon S3 adds 8 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Standard rates for this additional storage. • `IntelligentTieringAAStorage` – The number of bytes used for objects in the Archive Access tier of the `INTELLIGENT_TIERING` storage class. • `IntelligentTieringAIAStorage` – The number of bytes used for objects in the Archive Instant Access tier of the `INTELLIGENT_TIERING` storage class. • `IntelligentTieringDAAStorage` – The number of bytes used for objects in the Deep Archive Access tier of the `INTELLIGENT_TIERING` storage class. • `IntelligentTieringFAStorage` – The number of bytes used for objects in the Frequent Access tier of the `INTELLIGENT_TIERING` storage class.

Dimension	Description
	• `IntelligentTieringIAStorage` – The number of bytes used for objects in the Infrequent Access tier of the `INTELLIGENT_TIERING` storage class. • `OneZoneIASizeOverhead` – For objects smaller than 128 KB stored in the S3 One Zone-Infrequent Access (`ONEZONE_IA`) storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • `OneZoneIAStorage` – The number of bytes used for objects in the S3 One Zone-Infrequent Access (`ONEZONE_IA`) storage class. • `ReducedRedundancyStorage` – The number of bytes used for objects in the Reduced Redundancy Storage (RRS) class. • `StandardIASizeOverhead` – For objects smaller than 128 KB stored in the `STANDARD_IA` storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • `StandardIAStorage` – The number of bytes used for objects in the S3 Standard-Infrequent Access (`STANDARD_IA`) storage class. • `StandardStorage` – The number of bytes used for objects in the `STANDARD` storage class.
`FilterId`	This dimension filters metrics configurations that you specify for the request metrics on a bucket. When you create a metrics configuration, you specify a filter ID (for example, a prefix, a tag, or an access point). For more information, see Creating a metrics configuration.

S3 Replication dimensions in CloudWatch

The following dimensions are used to filter S3 Replication metrics.

Dimension	Description
SourceBucket	The name of the bucket objects are replicated from.
DestinationBucket	The name of the bucket objects are replicated to.
RuleId	A unique identifier for the rule that triggered this replication metric to update.

S3 Storage Lens dimensions in CloudWatch

For a list of dimensions that are used to filter S3 Storage Lens metrics in CloudWatch, see Dimensions.

S3 Object Lambda request dimensions in CloudWatch

The following dimensions are used to filter data from an Object Lambda Access Point.

Dimension	Description
AccessPointName	The name of the access point of which requests are being made.
DataSourceARN	The source the Object Lambda Access Point is retrieving the data from. If the request invokes a Lambda function this refers to the Lambda Amazon Resource Name (ARN). Otherwise this refers to the access point ARN.

Amazon S3 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon S3 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see AWS usage metrics in the *Amazon CloudWatch User Guide*.

Amazon S3 publishes the following metrics in the AWS/Usage namespace.

Metric	Description
`ResourceCount`	The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric.

The following dimensions are used to refine the usage metrics that are published by Amazon S3.

Dimension	Description
`Service`	The name of the AWS service containing the resource. For Amazon S3 usage metrics, the value for this dimension is S3.
`Type`	The type of entity that is being reported. Currently, the only valid value for Amazon S3 usage metrics is `Resource`.
`Resource`	The type of resource that is running. Currently, the only valid value for Amazon S3 usage metrics is `GeneralPurposeBuckets` , which returns the number of general purpose buckets in an AWS account. General purpose buckets allow objects that are stored across all storage classes, except S3 Express One Zone.

Accessing CloudWatch metrics

You can use the following procedures to view the storage metrics for Amazon S3. To get the Amazon S3 metrics involved, you must set a start and end timestamp. For metrics for any given 24-hour period, set the time period to 86400 seconds, the number of seconds in a day. Also, remember to set the `BucketName` and `StorageType` dimensions.

Using the AWS CLI

For example, if you want to use the AWS CLI to get the average of a specific bucket's size in bytes, you could use the following command:

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --namespace AWS/S3
 --start-time 2016-10-19T00:00:00Z --end-time 2016-10-20T00:00:00Z --statistics Average
```

```
 --unit Bytes --region us-west-2 --dimensions Name=BucketName,Value=amzn-s3-demo-bucket
 Name=StorageType,Value=StandardStorage --period 86400 --output json
```

This example produces the following output.

```
{
    "Datapoints": [
        {
            "Timestamp": "2016-10-19T00:00:00Z",
            "Average": 1025328.0,
            "Unit": "Bytes"
        }
    ],
    "Label": "BucketSizeBytes"
}
```

Using the S3 console

To view metrics by using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Metrics**.
3. Choose the **S3** namespace.
4. (Optional) To view a metric, enter the metric name in the search box.
5. (Optional) To filter by the **StorageType** dimension, enter the name of the storage class in the search box.

To view a list of valid metrics stored for your AWS account by using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/S3"
```

For more information about the permissions required to access CloudWatch dashboards, see Amazon CloudWatch dashboard permissions in the *Amazon CloudWatch User Guide*.

CloudWatch metrics configurations

With Amazon CloudWatch request metrics for Amazon S3, you can receive 1-minute CloudWatch metrics, set CloudWatch alarms, and access CloudWatch dashboards to view near-real-time operations and performance of your Amazon S3 storage. For applications that depend on cloud storage, these metrics let you quickly identify and act on operational issues. When enabled, these 1-minute metrics are available at the Amazon S3 bucket-level, by default.

If you want to get the CloudWatch request metrics for the objects in a bucket, you must create a metrics configuration for the bucket. For more information, see Creating a CloudWatch metrics configuration for all the objects in your bucket.

You can also use a shared prefix, object tags, or an access point to define a filter for the metrics collected. This method of defining a filter allows you to align metrics filters to specific business applications, workflows, or internal organizations. For more information, see Creating a metrics configuration that filters by prefix, object tag, or access point. For more information about the CloudWatch metrics that are available and the differences between storage and request metrics, see Monitoring metrics with Amazon CloudWatch.

Keep the following in mind when using metrics configurations:

- You can have a maximum of 1,000 metrics configurations per bucket.
- You can choose which objects in a bucket to include in metrics configurations by using filters. You can filter on a shared prefix, object tag, or access point to align metrics filters to specific business applications, workflows, or internal organizations. To request metrics for the entire bucket, create a metrics configuration without a filter.
- Metrics configurations are necessary only to enable request metrics. Bucket-level daily storage metrics are always turned on, and are provided at no additional cost. Currently, it's not possible to get daily storage metrics for a filtered subset of objects.
- Each metrics configuration enables the full set of available request metrics. Operation-specific metrics (such as `PostRequests`) are reported only if there are requests of that type for your bucket or your filter.
- Request metrics are reported for object-level operations. They are also reported for operations that list bucket contents, like GET Bucket (List Objects), GET Bucket Object Versions, and List Multipart Uploads, but they are not reported for other operations on buckets.
- Request metrics support filtering by prefix, object tags, or access point, but storage metrics do not.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

For more information about working with CloudWatch metrics in Amazon S3, see the following topics.

Topics

- Creating a CloudWatch metrics configuration for all the objects in your bucket
- Creating a metrics configuration that filters by prefix, object tag, or access point
- Deleting a metrics filter

Creating a CloudWatch metrics configuration for all the objects in your bucket

When you configure request metrics, you can create a CloudWatch metrics configuration for all the objects in your bucket, or you can filter by prefix, object tag, or access point. The procedures in this topic show you how to create a configuration for all the objects in your bucket. To create a configuration that filters by object tag, prefix, or access point, see Creating a metrics configuration that filters by prefix, object tag, or access point.

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With

replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see Monitoring metrics with Amazon CloudWatch.

You can add metrics configurations to a bucket using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the objects you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

   Names can only contain letters, numbers, periods, dashes, and underscores. We recommend using the name `EntireBucket` for a filter that applies to all objects.
9. Under **Filter scope**, choose **This filter applies to all objects in the bucket**.

   You can also define a filter so that the metrics are only collected and reported on a subset of objects in the bucket. For more information, see Creating a metrics configuration that filters by prefix, object tag, or access point.
10. Choose **Save changes**.
11. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

    After about 15 minutes, CloudWatch begins tracking these request metrics. You can see them on the **Request metrics** tab. You can see graphs for the metrics on the Amazon S3 or CloudWatch console. Request metrics are billed at the standard CloudWatch rate. For more information, see Amazon CloudWatch pricing.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PUT Bucket Metric Configuration
- GET Bucket Metric Configuration
- List Bucket Metric Configuration
- DELETE Bucket Metric Configuration

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see Installing, updating, and uninstalling the AWS CLI in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. Run the following command to add a metrics configuration.

```
aws s3api put-bucket-metrics-configuration --endpoint https://s3.us-
west-2.amazonaws.com --bucket bucket-name --id metrics-config-id --metrics-
configuration '{"Id":"metrics-config-id"}'
```

Creating a metrics configuration that filters by prefix, object tag, or access point

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see Monitoring metrics with Amazon CloudWatch.

When you configure CloudWatch metrics, you can create a filter for all the objects in your bucket, or you can filter the configuration into groups of related objects within a single bucket. You can filter objects in a bucket for inclusion in a metrics configuration based on one or more of the following filter types:

- **Object key name prefix** – Although the Amazon S3 data model is a flat structure, you can infer a hierarchy by using a prefix. The Amazon S3 console supports these prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see Organizing objects using prefixes.
- **Tag** – You can add tags, which are key-value name pairs, to objects. Tags help you find and organize objects easily. You can also use tags as filters for metrics configurations. For more information about object tags, see Tagging your objects.
- **Access point** – S3 Access Points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. When you create an access point filter, Amazon S3 includes requests to the access point that you specify in the metrics configuration. For more information, see Monitoring and logging access points.

> **Note**
>
> When you create a metrics configuration that filters by access point, you must use the access point Amazon Resource Name (ARN), not the access point alias. Make sure that you use the ARN for the access point itself, not the ARN for a specific object. For more information about access point ARNs, see Using Amazon S3 access points for general purpose buckets.

If you specify a filter, only requests that operate on single objects can match the filter and be included in the reported metrics. Requests like DeleteObjects and `ListObjects` requests don't return any metrics for configurations with filters.

To request more complex filtering, choose two or more elements. Only objects that have all of those elements are included in the metrics configuration. If you don't set filters, all of the objects in the bucket are included in the metrics configuration.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **General purpose buckets**
3. In the buckets list, choose the name of the bucket that contains the objects that you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

   Names can contain only letters, numbers, periods, dashes, and underscores.
9. Under **Filter scope**, choose **Limit the scope of this filter using a prefix, object tags, and an S3 Access Point, or a combination of all three**.
10. Under **Filter type**, choose at least one filter type: **Prefix**, **Object tags**, or **Access Point**.
11. To define a prefix filter and limit the scope of the filter to a single path, in the **Prefix** box, enter a prefix.
12. To define an object tags filter, under **Object tags**, choose **Add tag**, and then enter a tag **Key** and **Value**.
13. To define an access point filter, in the **S3 Access Point** field, enter the access point ARN, or choose **Browse S3** to navigate to the access point.

    > **Important**
    >
    > You cannot enter an access point alias. You must enter the ARN for the access point itself, not the ARN for a specific object.
14. Choose **Save changes**.

    Amazon S3 creates a filter that uses the prefix, tags, or access point that you specified.
15. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

    You have now created a filter that limits the request metrics scope by prefix, object tags, or access point. About 15 minutes after CloudWatch begins tracking these request metrics, you can see charts for the metrics on both the Amazon S3 and CloudWatch consoles. Request metrics are billed at the standard CloudWatch rate. For more information, see Amazon CloudWatch pricing.

You can also configure request metrics at the bucket level. For information, see Creating a CloudWatch metrics configuration for all the objects in your bucket.

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see Installing, updating, and uninstalling the AWS CLI in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. To add a metrics configuration, run one of the following commands:

Example: To filter by prefix

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --
id metrics-config-id --metrics-configuration '{"Id":"metrics-config-id", "Filter":
{"Prefix":"prefix1"}} '
```

Example: To filter by tags

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --
id metrics-config-id --metrics-configuration '{"Id":"metrics-config-id", "Filter":
{"Tag": {"Key": "string", "Value": "string"}} '
```

Example: To filter by access point

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --
id metrics-config-id --metrics-configuration '{"Id":"metrics-config-id", "Filter":
{"AccessPointArn":"arn:aws:s3:Region:account-id:accesspoint/access-point-name"}} '
```

Example: To filter by prefix, tags, and access point

```
aws s3api put-bucket-metrics-configuration --endpoint https://
s3.Region.amazonaws.com --bucket amzn-s3-demo-bucket --id metrics-config-id --
metrics-configuration '
{
    "Id": "metrics-config-id",
    "Filter": {
        "And": {
            "Prefix": "string",
```

```
            "Tags": [
                {
                    "Key": "string",
                    "Value": "string"
                }
            ],
            "AccessPointArn": "arn:aws:s3:Region:account-id:accesspoint/access-
point-name"
        }
    }
}'
```

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PUT Bucket Metric Configuration
- GET Bucket Metric Configuration
- List Bucket Metric Configuration
- DELETE Bucket Metric Configuration

Deleting a metrics filter

You can delete an Amazon CloudWatch request metrics filter if you no longer need it. When you delete a filter, you stop being charged for request metrics that use that *specific filter*. However, charges still apply for any other filters that remain.

You cannot undo a filter deletion. After you delete a filter, you can no longer use it for request metrics.

To create a request metrics filter, see the following topics:

- Creating a CloudWatch metrics configuration for all the objects in your bucket
- Creating a metrics configuration that filters by prefix, object tag, or access point

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket you want to delete a request metrics filter for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Manage filters**.
8. Choose your filter.

   > **Important**
   >
   > Deleting a filter cannot be undone.

9. Choose **Delete**.

   Amazon S3 deletes your filter.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PUT Bucket Metric Configuration
- GET Bucket Metric Configuration
- List Bucket Metric Configuration
- DELETE Bucket Metric Configuration

Amazon S3 Event Notifications

You can use the Amazon S3 Event Notifications feature to receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that

identifies the events that you want Amazon S3 to publish. Make sure that it also identifies the destinations where you want Amazon S3 to send the notifications. You store this configuration in the *notification* subresource that's associated with a bucket. For more information, see General purpose buckets configuration options. Amazon S3 provides an API for you to manage this subresource.

> **Important**
>
> Amazon S3 event notifications are designed to be delivered at least once. Typically, event notifications are delivered in seconds but can sometimes take a minute or longer.

Overview of Amazon S3 Event Notifications

Currently, Amazon S3 can publish notifications for the following events:

- New object created events
- Object removal events
- Restore object events
- Reduced Redundancy Storage (RRS) object lost events
- Replication events
- S3 Lifecycle expiration events
- S3 Lifecycle transition events
- S3 Intelligent-Tiering automatic archival events
- Object tagging events
- Object ACL PUT events
- Object Annotation events
- Object Retention events

For full descriptions of all the supported event types, see Supported event types for SQS, SNS, and Lambda.

Amazon S3 can send event notification messages to the following destinations. You specify the Amazon Resource Name (ARN) value of these destinations in the notification configuration.

- Amazon Simple Notification Service (Amazon SNS) topics

- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda function
- Amazon EventBridge

For more information, see Supported event destinations.

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Note

AWS Lambda durable functions aren't supported as an Amazon S3 event notification destination.

Warning

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.
For more information and an example of using Amazon S3 notifications with AWS Lambda, see Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

For more information about the number of event notification configurations that you can create per bucket, see Amazon S3 service quotas in *AWS General Reference*.

For more information about event notifications, see the following sections.

Topics

- Event notification types and destinations
- Using Amazon SQS, Amazon SNS, and Lambda
- Using EventBridge

Event notification types and destinations

Amazon S3 supports several event notification types and destinations where the notifications can be published. You can specify the event type and destination when configuring your event notifications. Only one destination can be specified for each event notification. Amazon S3 event notifications send one event entry for each notification message.

Topics

- Supported event destinations
- Supported event types for SQS, SNS, and Lambda
- Supported event types for Amazon EventBridge
- Event ordering and duplicate events

Supported event destinations

Amazon S3 can send event notification messages to the following destinations.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda
- Amazon EventBridge

However, only one destination type can be specified for each event notification.

> **Note**
>
> You must grant Amazon S3 permissions to post messages to an Amazon SNS topic or an Amazon SQS queue. You must also grant Amazon S3 permission to invoke an AWS Lambda function on your behalf. For instructions on how to grant these permissions, see Granting permissions to publish event notification messages to a destination.

Amazon SNS topic

Amazon SNS is a flexible, fully managed push messaging service. You can use this service to push messages to mobile devices or distributed services. With SNS, you can publish a message once, and deliver it one or more times. Currently, Standard SNS is only allowed as an S3 event notification destination, whereas SNS FIFO is not allowed.

Amazon SNS both coordinates and manages sending and delivering messages to subscribing endpoints or clients. You can use the Amazon SNS console to create an Amazon SNS topic that your notifications can be sent to.

The topic must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SNS topic, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide* and the Amazon SNS FAQ.

Before you can use the Amazon SNS topic that you created as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SNS topic
- A valid Amazon SNS topic subscription. With it, topic subscribers are notified when a message is published to your Amazon SNS topic.

Amazon SQS queue

Amazon SQS offers reliable and scalable hosted queues for storing messages as they travel between computers. You can use Amazon SQS to transmit any volume of data without requiring other services to be always available. You can use the Amazon SQS console to create an Amazon SQS queue that your notifications can be sent to.

The Amazon SQS queue must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SQS queue, see What is Amazon Simple Queue Service and Getting started with Amazon SQS in the *Amazon Simple Queue Service Developer Guide*.

Before you can use the Amazon SQS queue as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SQS queue

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Amazon SQS message size

Amazon S3 event notification messages can be up to 64 KB. We recommend that you set the queue's `MaximumMessageSize` attribute to at least 64 KB. If an event notification exceeds the queue's configured `MaximumMessageSize`, Amazon SQS rejects the notification and doesn't deliver the event.

Lambda function

You can use AWS Lambda to extend other AWS services with custom logic, or create your own backend that operates at AWS scale, performance, and security. With Lambda, you can create discrete, event-driven applications that run only when needed. You can also use it to scale these applications automatically from a few requests a day to thousands a second.

Lambda can run custom code in response to Amazon S3 bucket events. You upload your custom code to Lambda and create what's called a Lambda function. When Amazon S3 detects an event of a specific type, it can publish the event to AWS Lambda and invoke your function in Lambda. In response, Lambda runs your function. One event type it might detect, for example, is an object created event.

You can use the AWS Lambda console to create a Lambda function that uses the AWS infrastructure to run the code on your behalf. The Lambda function must be in the same Region as your S3 bucket. You must also have the name or the ARN of a Lambda function to set up the Lambda function as an event notification destination.

Warning

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an

object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.
For more information and an example of using Amazon S3 notifications with AWS Lambda, see Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

Amazon EventBridge

Amazon EventBridge is a serverless event bus, which receives events from AWS services. You can set up rules to match events and deliver them to targets, such as an AWS service or an HTTP endpoint. For more information, see What is EventBridge in the *Amazon EventBridge User Guide*.

Unlike other destinations, you can either enable or disable events to be delivered to EventBridge for a bucket. If you enable delivery, all events are sent to EventBridge. Moreover, you can use EventBridge rules to route events to additional targets.

Supported event types for SQS, SNS, and Lambda

Amazon S3 can publish events of the following types. You specify these event types in the notification configuration.

Event types	Description
`s3:TestEvent`	When a notification is enabled, Amazon S3 publishes a test notification. This is to ensure that the topic exists and that the bucket owner has permission to publish the specified topic. If enabling the notification fails, you don't receive a test notification.

`s3:ObjectCreated:*`
 	
`s3:ObjectCreated:Put`
 	
`s3:ObjectCreated:Post`
 	
`s3:ObjectCreated:Copy`
	Amazon S3 API operations such as PUT, POST, and COPY can create an object. With these event types, you can enable notifications when an object is created using a specific API operation. Alternatively, you can use the `s3:ObjectCreated:*` event type to request notification regardless of the API that was used to create an object.

Event types	Description
s3:ObjectCreated:CompleteMultipartUpload	s3:ObjectCreated:CompleteMultipartUpload includes objects that are created using UploadPartCopy for Copy operations.
s3:ObjectRemoved:* s3:ObjectRemoved:Delete s3:ObjectRemoved:DeleteMarkerCreated	By using the ObjectRemoved event types, you can enable notification when an object or a batch of objects is removed from a bucket. You can request notification when an object is deleted or a versioned object is permanently deleted by using the s3:ObjectRemoved:Delete event type. Alternatively, you can request notification when a delete marker is created for a versioned object using s3:ObjectRemoved:DeleteMarkerCreated. For instructions on how to delete versioned objects, see Deleting object versions from a versioning-enabled bucket. You can also use a wildcard s3:ObjectRemoved:* to request notification anytime an object is deleted. These event notifications don't alert you for automatic deletes from lifecycle configurations or from failed operations.

Event types	Description

`s3:ObjectRestore:*`
 	
`s3:ObjectRestore:Post`
 	
`s3:ObjectRestore:Completed`
 	
`s3:ObjectRestore:Delete`
	By using the `ObjectRestore` event types, you can receive notifications for event initiation and completion when restoring objects from the S3 Glacier Flexible Retrieval storage class, S3 Glacier Deep Archive storage class, S3 Intelligent-Tiering Archive Access tier, and S3 Intelligent-Tiering Deep Archive Access tier. You can also receive notifications for when the restored copy of an object expires.
	
	The `s3:ObjectRestore:Post` event type notifies you of object restoration initiation. The `s3:ObjectRestore:Completed` event type notifies you of restoration completion. The `s3:ObjectRestore:Delete` event type notifies you when the temporary copy of a restored object expires.

`s3:ReducedRedundancyLostObject`	You receive this notification event when Amazon S3 detects that an object of the RRS storage class is lost.

Event types	Description

`s3:Replication:*`
 	
`s3:Replication:OperationFailedReplication`
 	
`s3:Replication:OperationMissedThreshold`
 	
`s3:Replication:OperationReplicatedAfterThreshold`
 	
`s3:Replication:OperationNotTracked`
	By using the `Replication` event types, you can receive notifications for replication configurations that have S3 Replication metrics or S3 Replication Time Control (S3 RTC) enabled. You can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For information about replication metrics, see Monitoring replication with metrics, event notifications, and statuses.
	
	• The `s3:Replication:OperationFailedReplication` event type notifies you when an object that was eligible for replication failed to replicate.
	• The `s3:Replication:OperationMissedThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.
	• The `s3:Replication:OperationReplicatedAfterThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.
	• The `s3:Replication:OperationNotTracked` event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

Event types	Description
s3:LifecycleExpiration:* s3:LifecycleExpiration:Delete s3:LifecycleExpiration:DeleteMarkerCreated	By using the LifecycleExpiration event types, you can receive a notification when Amazon S3 deletes an object based on your S3 Lifecycle configuration. The s3:LifecycleExpiration:Delete event type notifies you when an object in an unversioned bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration. The s3:LifecycleExpiration:DeleteMarkerCreated event type notifies you when S3 Lifecycle creates a delete marker when a current version of an object in versioned bucket is deleted.
s3:LifecycleTransition	You receive this notification event when an object is transitioned to another Amazon S3 storage class by an S3 Lifecycle configuration.
s3:IntelligentTiering	You receive this notification event when an object within the S3 Intelligent-Tiering storage class moved to the Archive Access tier or Deep Archive Access tier.
s3:ObjectTagging:* s3:ObjectTagging:Put s3:ObjectTagging:Delete	By using the ObjectTagging event types, you can enable notification when an object tag is added or deleted from an object. The s3:ObjectTagging:Put event type notifies you when a tag is PUT on an object or an existing tag is updated. The s3:ObjectTagging:Delete event type notifies you when a tag is removed from an object.

Event types	Description

`s3:ObjectAnnotation:*`
 	
`s3:ObjectAnnotation:Put`
 	
`s3:ObjectAnnotation:Delete`
	By using the `ObjectAnnotation` event types, you can enable notification when an annotation is created, updated, or deleted on an object.
	
	The `s3:ObjectAnnotation:Put` event type notifies you when an annotation is created or updated through `PutObjectAnnotation`. The `s3:ObjectAnnotation:Delete` event type notifies you when an annotation is deleted through `DeleteObjectAnnotation`.

`s3:ObjectAcl:Put`	You receive this notification event when an ACL is PUT on an object or when an existing ACL is changed. An event is not generated when a request results in no change to an object's ACL.
`s3:ObjectRetention:Put`	You receive this notification event when you set a retention configuration on an object using `PutObjectRetention`. This includes setting fixed or variable retention, releasing an event hold, modifying the event hold duration, and changing the retain-until-date.

Note

Note the following behavior for annotation event notifications:

- `PutObjectAnnotation` and `DeleteObjectAnnotation` send only annotation-specific events. They do not send object-level events such as `s3:ObjectCreated:*`.
- `GetObjectAnnotation` and `ListObjectAnnotations` do not send event notifications.
- `CopyObject` sends the standard `s3:ObjectCreated:Copy` event. If the copied object has annotations, the event includes a `hasObjectAnnotation` field set to `true`.
- `DeleteObject` does not include annotation-related fields in the event payload.
- Prefix and suffix filters apply to object keys only, not to annotation names.

Supported event types for Amazon EventBridge

For a list of event types Amazon S3 will send to Amazon EventBridge, see Using EventBridge.

Event ordering and duplicate events

Amazon S3 Event Notifications is designed to deliver notifications at least once, but they aren't guaranteed to arrive in the same order that the events occurred. On rare occasions, Amazon S3's retry mechanism might cause duplicate S3 Event Notifications for the same object event. For more about handling duplicate or out of order events, see Manage event ordering and duplicate events with Amazon S3 Event Notifications on the *AWS Storage Blog*.

Using Amazon SQS, Amazon SNS, and Lambda

Enabling notifications is a bucket-level operation. You store notification configuration information in the *notification* subresource that's associated with a bucket. After you create or change the bucket notification configuration, it usually takes about five minutes for the changes to take effect. When the notification is first enabled, an `s3:TestEvent` occurs. You can use any of the following methods to manage notification configuration:

- **Using the Amazon S3 console** — You can use the console UI to set a notification configuration on a bucket without having to write any code. For more information, see Enabling and configuring event notifications using the Amazon S3 console.
- **Programmatically using the AWS SDKs** — Internally, both the console and the SDKs call the Amazon S3 REST API to manage *notification* subresources that are associated with the bucket. For examples of notification configurations that use AWS SDK, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).

> **Note**
>
> You can also make the Amazon S3 REST API calls directly from your code. However, this can be cumbersome because to do so you must write code to authenticate your requests.

Regardless of the method that you use, Amazon S3 stores the notification configuration as XML in the *notification* subresource that's associated with a bucket. For information about bucket subresources, see General purpose buckets configuration options.

> **Note**
>
> If you have multiple failed event notifications due to deleted destinations you may receive the **Unable to validate the following destination configurations** when trying to delete them. You can resolve this in the S3 console by deleting all the failed notifications at the same time.

Topics

- Granting permissions to publish event notification messages to a destination
- Enabling and configuring event notifications using the Amazon S3 console
- Configuring event notifications programmatically
- Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)
- Configuring event notifications using object key name filtering
- Event message structure

Granting permissions to publish event notification messages to a destination

You must grant the Amazon S3 principal the necessary permissions to call the relevant API to publish messages to an SNS topic, an SQS queue, or a Lambda function. This is so that Amazon S3 can publish event notification messages to a destination.

To troubleshoot publishing event notification messages to a destination, see Troubleshoot to publish Amazon S3 event notifications to an Amazon Simple Notification Service topic .

Topics

- Granting permissions to invoke an AWS Lambda function
- Granting permissions to publish messages to an SNS topic or an SQS queue

Granting permissions to invoke an AWS Lambda function

Amazon S3 publishes event messages to AWS Lambda by invoking a Lambda function and providing the event message as an argument.

When you use the Amazon S3 console to configure event notifications on an Amazon S3 bucket for a Lambda function, the console sets up the necessary permissions on the Lambda function. This is

so that Amazon S3 has permissions to invoke the function from the bucket. For more information, see Enabling and configuring event notifications using the Amazon S3 console.

You can also grant Amazon S3 permissions from AWS Lambda to invoke your Lambda function. For more information, see Tutorial: Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

Granting permissions to publish messages to an SNS topic or an SQS queue

To grant Amazon S3 permissions to publish messages to the SNS topic or SQS queue, attach an AWS Identity and Access Management (IAM) policy to the destination SNS topic or SQS queue.

For an example of how to attach a policy to an SNS topic or an SQS queue, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue). For more information about permissions, see the following topics:

- Example cases for Amazon SNS access control in the *Amazon Simple Notification Service Developer Guide*
- Identity and access management in Amazon SQS in the *Amazon Simple Queue Service Developer Guide*

IAM policy for a destination SNS topic

The following is an example of an AWS Identity and Access Management (IAM) policy that you attach to the destination SNS topic. For instructions on how to use this policy to set up a destination Amazon SNS topic for event notifications, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).

JSON

```
{
    "Version":"2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "Example SNS topic policy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
```

```
            },
            "Action": [
                "SNS:Publish"
            ],
            "Resource": "arn:aws:sns:us-east-1:111122223333:example-sns-topic",
            "Condition": {
                "ArnEquals": {
                    "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
                },
                "StringEquals": {
                    "aws:SourceAccount": "bucket-owner-123456789012"
                }
            }
        }
    ]
}
```

IAM policy for a destination SQS queue

The following is an example of an IAM policy that you attach to the destination SQS queue. For instructions on how to use this policy to set up a destination Amazon SQS queue for event notifications, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).

To use this policy, you must update the Amazon SQS queue ARN, bucket name, and bucket owner's AWS account ID.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "SQS:SendMessage"
            ],
```

```
            "Resource": "arn:aws:sqs:us-east-1:111122223333:queue-name",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:*:*:amzn-s3-demo-bucket"
                },
                "StringEquals": {
                    "aws:SourceAccount": "bucket-owner-123456789012"
                }
            }
        }
    ]
}
```

For both the Amazon SNS and Amazon SQS IAM policies, you can specify the `StringLike` condition in the policy instead of the `ArnLike` condition.

When `ArnLike` is used, the partition, service, account ID, resource type, and partial resource ID portions of the ARN must exactly match to the ARN in the request context. Only the Region and resource path allow partial matching.

When `StringLike` is used instead of `ArnLike`, matching ignores the ARN structure and allows partial matching, regardless of the portion that's replaced by the wildcard character. For more information, see IAM JSON policy elements in the *IAM User Guide*.

```
"Condition": {
  "StringLike": { "aws:SourceArn": "arn:aws:s3:*:*:amzn-s3-demo-bucket" }
  }
```

AWS KMS key policy

If the SQS queue or SNS topics are encrypted with an AWS Key Management Service (AWS KMS) customer managed key, you must grant the Amazon S3 service principal permission to work with the encrypted topics or queue. To grant the Amazon S3 service principal permission, add the following statement to the key policy for the customer managed key.

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about AWS KMS key policies, see Using key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

For more information about using server-side encryption with AWS KMS for Amazon SQS and Amazon SNS, see the following:

- Key management in the *Amazon Simple Notification Service Developer Guide*.
- Key management in the *Amazon Simple Queue Service Developer Guide*.
- Encrypting messages published to Amazon SNS with AWS KMS in the *AWS Compute Blog*.

Enabling and configuring event notifications using the Amazon S3 console

You can enable certain Amazon S3 general purpose bucket events to send a notification message to a destination whenever those events occur. This section explains how to use the Amazon S3 console to enable event notifications. For information about how to use event notifications with the AWS SDKs and the Amazon S3 REST APIs, see Configuring event notifications programmatically.

Prerequisites: Before you can enable event notifications for your bucket, you must set up one of the destination types and then configure permissions. For more information, see Supported event destinations and Granting permissions to publish event notification messages to a destination.

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Topics

- Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console

Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console

To enable and configure event notifications for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and choose **Create event notification**.
6. In the **General configuration** section, specify descriptive event name for your event notification. Optionally, you can also specify a prefix and a suffix to limit the notifications to objects with keys ending in the specified characters.

   a. Enter a description for the **Event name**.

      If you don't enter a name, a globally unique identifier (GUID) is generated and used for the name.

   b. (Optional) To filter event notifications by prefix, enter a **Prefix**.

      For example, you can set up a prefix filter so that you receive notifications only when files are added to a specific folder (for example, `images/`).

   c. (Optional) To filter event notifications by suffix, enter a **Suffix**.

      For more information, see Configuring event notifications using object key name filtering.

7. In the **Event types** section, select one or more event types that you want to receive notifications for.

   For a list of the different event types, see Supported event types for SQS, SNS, and Lambda.

8. In the **Destination** section, choose the event notification destination.

   > **Note**
   >
   > Before you can publish event notifications, you must grant the Amazon S3 principal the necessary permissions to call the relevant API. This is so that it can publish notifications to a Lambda function, SNS topic, or SQS queue.

   a. Select the destination type: **Lambda Function**, **SNS Topic**, or **SQS Queue**.

   b. After you choose your destination type, choose a function, topic, or queue from the list.

   c. Or, if you prefer to specify an Amazon Resource Name (ARN), select **Enter ARN** and enter the ARN.

   For more information, see Supported event destinations.

9. Choose **Save changes**, and Amazon S3 sends a test message to the event notification destination.

Configuring event notifications programmatically

By default, notifications aren't enabled for any type of event. Therefore, the *notification* subresource initially stores an empty configuration.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</NotificationConfiguration>
```

To enable notifications for events of specific types, you replace the XML with the appropriate configuration that identifies the event types you want Amazon S3 to publish and the destination where you want the events published. For each destination, you add a corresponding XML configuration.

To publish event messages to an SQS queue

To set an SQS queue as the notification destination for one or more event types, add the `QueueConfiguration`.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>optional-id-string</Id>
    <Queue>sqs-queue-arn</Queue>
    <Event>event-type</Event>
    <Event>event-type</Event>
     ...
  </QueueConfiguration>
   ...
</NotificationConfiguration>
```

To publish event messages to an SNS topic

To set an SNS topic as the notification destination for specific event types, add the `TopicConfiguration`.

```
<NotificationConfiguration>
  <TopicConfiguration>
     <Id>optional-id-string</Id>
     <Topic>sns-topic-arn</Topic>
     <Event>event-type</Event>
     <Event>event-type</Event>
      ...
  </TopicConfiguration>
   ...
</NotificationConfiguration>
```

To invoke the AWS Lambda function and provide an event message as an argument

To set a Lambda function as the notification destination for specific event types, add the `CloudFunctionConfiguration`.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
     <Id>optional-id-string</Id>
     <CloudFunction>cloud-function-arn</CloudFunction>
     <Event>event-type</Event>
     <Event>event-type</Event>
      ...
```

```
  </CloudFunctionConfiguration>
   ...
</NotificationConfiguration>
```

To remove all notifications configured on a bucket

To remove all notifications configured on a bucket, save an empty `<NotificationConfiguration/>` element in the *notification* subresource.

When Amazon S3 detects an event of the specific type, it publishes a message with the event information. For more information, see Event message structure.

For more information about configuring event notifications, see the following topics:

- Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).
- Configuring event notifications using object key name filtering

Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)

You can receive Amazon S3 notifications using Amazon Simple Notification Service (Amazon SNS) or Amazon Simple Queue Service (Amazon SQS). In this walkthrough, you add a notification configuration to your bucket using an Amazon SNS topic and an Amazon SQS queue.

> **Note**
>
> Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Topics

- Walkthrough summary
- Step 1: Create an Amazon SQS queue
- Step 2: Create an Amazon SNS topic
- Step 3: Add a notification configuration to your bucket
- Step 4: Test the setup

Walkthrough summary

This walkthrough helps you do the following:

- Publish events of the `s3:ObjectCreated:*` type to an Amazon SQS queue.
- Publish events of the `s3:ReducedRedundancyLostObject` type to an Amazon SNS topic.

For information about notification configuration, see Using Amazon SQS, Amazon SNS, and Lambda.

You can do all these steps using the console, without writing any code. In addition, code examples using AWS SDKs for Java and .NET are also provided to help you add notification configurations programmatically.

The procedure includes the following steps:

1. Create an Amazon SQS queue.

   Using the Amazon SQS console, create an SQS queue. You can access any messages Amazon S3 sends to the queue programmatically. But, for this walkthrough, you verify notification messages in the console.

   You attach an access policy to the queue to grant Amazon S3 permission to post messages.
2. Create an Amazon SNS topic.

   Using the Amazon SNS console, create an SNS topic and subscribe to the topic. That way, any events posted to it are delivered to you. You specify email as the communications protocol. After you create a topic, Amazon SNS sends an email. You use the link in the email to confirm the topic subscription.

   You attach an access policy to the topic to grant Amazon S3 permission to post messages.
3. Add notification configuration to a bucket.

Step 1: Create an Amazon SQS queue

Follow the steps to create and subscribe to an Amazon Simple Queue Service (Amazon SQS) queue.

1. Using the Amazon SQS console, create a queue. For instructions, see Getting Started with Amazon SQS in the *Amazon Simple Queue Service Developer Guide*.

2. Replace the access policy that's attached to the queue with the following policy.

   a. In the Amazon SQS console, in the **Queues** list, choose the queue name.

   b. On the **Access policy** tab, choose **Edit**.

   c. Replace the access policy that's attached to the queue. In it, provide your Amazon SQS ARN, source bucket name, and bucket owner account ID.

      JSON

```
{
    "Version":"2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "SQS:SendMessage"
            ],
            "Resource": "arn:aws:sqs:us-west-2:111122223333:s3-
notification-queue",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:*:*:awsexamplebucket1"
                },
                "StringEquals": {
                    "aws:SourceAccount": "bucket-owner-123456789012"
                }
            }
        }
    ]
}
```

   d. Choose **Save**.

3. (Optional) If the Amazon SQS queue or the Amazon SNS topic is server-side encryption enabled with AWS Key Management Service (AWS KMS), add the following policy to the associated symmetric encryption customer managed key.

You must add the policy to a customer managed key because you cannot modify the AWS managed key for Amazon SQS or Amazon SNS.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about using SSE for Amazon SQS and Amazon SNS with AWS KMS, see the following:

- Key management in the *Amazon Simple Notification Service Developer Guide*.
- Key management in the *Amazon Simple Queue Service Developer Guide*.

4. Note the queue ARN.

   The SQS queue that you created is another resource in your AWS account. It has a unique Amazon Resource Name (ARN). You need this ARN in the next step. The ARN is of the following format:

   ```
   arn:aws:sqs:aws-region:account-id:queue-name
   ```

Step 2: Create an Amazon SNS topic

Follow the steps to create and subscribe to an Amazon SNS topic.

1. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.
2. Subscribe to the topic. For this exercise, use email as the communications protocol. For instructions, see Subscribing to an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

   You get an email requesting you to confirm your subscription to the topic. Confirm the subscription.
3. Replace the access policy attached to the topic with the following policy. In it, provide your SNS topic ARN, bucket name, and bucket owner's account ID.

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "SNS:Publish"
            ],
            "Resource": "arn:aws:sns:us-west-2:111122223333:s3-notification-topic",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:*:*:awsexamplebucket1"
                },
                "StringEquals": {
                    "aws:SourceAccount": "bucket-owner-123456789012"
                }
            }
        }
    ]
}
```

4. Note the topic ARN.

The SNS topic you created is another resource in your AWS account, and it has a unique ARN. You will need this ARN in the next step. The ARN will be of the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

Step 3: Add a notification configuration to your bucket

You can enable bucket notifications either by using the Amazon S3 console or programmatically by using AWS SDKs. Choose any one of the options to configure notifications on your bucket. This section provides code examples using the AWS SDKs for Java and .NET.

Option A: Enable notifications on a bucket using the console

Using the Amazon S3 console, add a notification configuration requesting Amazon S3 to do the following:

- Publish events of the **All object create events** type to your Amazon SQS queue.
- Publish events of the **Object in RRS lost** type to your Amazon SNS topic.

After you save the notification configuration, Amazon S3 posts a test message, which you get through email.

For instructions, see Enabling and configuring event notifications using the Amazon S3 console.

Option B: Enable notifications on a bucket using the AWS SDKs

.NET

The following C# code example provides a complete code listing that adds a notification configuration to a bucket. You must update the code and provide your bucket name and SNS topic ARN. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
```

```
namespace Amazon.DocSamples.S3
{
    class EnableNotificationsTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string snsTopic = "*** SNS topic ARN ***";
        private const string sqsQueue = "*** SQS topic ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            EnableNotificationAsync().Wait();
        }

        static async Task EnableNotificationAsync()
        {
            try
            {
               PutBucketNotificationRequest request = new
 PutBucketNotificationRequest
                {
                    BucketName = bucketName
                };

                TopicConfiguration c = new TopicConfiguration
                {
                    Events = new List<EventType> { EventType.ObjectCreatedCopy },
                    Topic = snsTopic
                };
                request.TopicConfigurations = new List<TopicConfiguration>();
                request.TopicConfigurations.Add(c);
                request.QueueConfigurations = new List<QueueConfiguration>();
                request.QueueConfigurations.Add(new QueueConfiguration()
                {
                    Events = new List<EventType> { EventType.ObjectCreatedPut },
                    Queue = sqsQueue
                });
```

```
                PutBucketNotificationResponse response = await
 client.PutBucketNotificationAsync(request);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' ",
 e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown error encountered on server.
 Message:'{0}' ", e.Message);
            }
        }
    }
}
```

Java

For examples of how to configure bucket notifications with the AWS SDK for Java, see Process S3 event notifications in the *Amazon S3 API Reference*.

Step 4: Test the setup

Now, you can test the setup by uploading an object to your bucket and verifying the event notification in the Amazon SQS console. For instructions, see Receiving a Message in the *Amazon Simple Queue Service Developer Guide "Getting Started" section*.

Configuring event notifications using object key name filtering

When configuring an Amazon S3 event notification, you must specify which supported Amazon S3 event types cause Amazon S3 to send the notification. If an event type that you didn't specify occurs in your S3 bucket, Amazon S3 doesn't send the notification.

You can configure notifications to be filtered by the prefix and suffix of the key name of objects. For example, you can set up a configuration where you're sent a notification only when image files with a "`.jpg`" file name extension are added to a bucket. Or, you can have a configuration that delivers a notification to an Amazon SNS topic when an object with the prefix "`images/`" is added to the bucket, while having notifications for objects with a "`logs/`" prefix in the same bucket delivered to an AWS Lambda function.

Note

A wildcard character ("*") can't be used in filters as a prefix or suffix. If your prefix or suffix contains a space, you must replace it with the "+" character. If you use any other special characters in the value of the prefix or suffix, you must enter them in URL-encoded (percent-encoded) format. For a complete list of special characters that must be converted to URL-encoded format when used in a prefix or suffix for event notifications, see Safe characters.

You can set up notification configurations that use object key name filtering in the Amazon S3 console. You can do so by using Amazon S3 APIs through the AWS SDKs or the REST APIs directly. For information about using the console UI to set a notification configuration on a bucket, see Enabling and configuring event notifications using the Amazon S3 console.

Amazon S3 stores the notification configuration as XML in the *notification* subresource associated with a bucket as described in Using Amazon SQS, Amazon SNS, and Lambda. You use the `Filter` XML structure to define the rules for notifications to be filtered by the prefix or suffix of an object key name. For information about the `Filter` XML structure, see PUT Bucket notification in the *Amazon Simple Storage Service API Reference*.

Notification configurations that use `Filter` cannot define filtering rules with overlapping prefixes, overlapping suffixes, or prefix and suffix overlapping. The following sections have examples of valid notification configurations with object key name filtering. They also contain examples of notification configurations that are not valid because of prefix and suffix overlapping.

Topics

- Examples of valid notification configurations with object key name filtering
- Examples of notification configurations with invalid prefix and suffix overlapping

Examples of valid notification configurations with object key name filtering

The following notification configuration contains a queue configuration identifying an Amazon SQS queue for Amazon S3 to publish events to of the `s3:ObjectCreated:Put` type. The events are published whenever an object that has a prefix of `images/` and a `jpg` suffix is PUT to a bucket.

```
<NotificationConfiguration>
  <QueueConfiguration>
```

```
      <Id>1</Id>
      <Filter>
          <S3Key>
              <FilterRule>
                  <Name>prefix</Name>
                  <Value>images/</Value>
              </FilterRule>
              <FilterRule>
                  <Name>suffix</Name>
                  <Value>jpg</Value>
              </FilterRule>
          </S3Key>
      </Filter>
      <Queue>arn:aws:sqs:us-west-2:444455556666:s3notificationqueue</Queue>
      <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping prefixes. The configuration defines that notifications for PUT requests in the `images/` folder go to queue-A, while notifications for PUT requests in the `logs/` folder go to queue-B.

```
<NotificationConfiguration>
  <QueueConfiguration>
     <Id>1</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images/</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-A</Queue>
     <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
  <QueueConfiguration>
     <Id>2</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>logs/</Value>
```

```
                </FilterRule>
            </S3Key>
     </Filter>
     <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-B</Queue>
     <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping suffixes. The configuration defines that all `.jpg` images newly added to the bucket are processed by Lambda cloud-function-A, and all newly added `.png` images are processed by cloud-function-B. The `.png` and `.jpg` suffixes aren't overlapping even though they have the same last letter. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can't end with both `.png` and `.jpg`, so the suffixes in the example configuration aren't overlapping suffixes.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
     <Id>1</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.jpg</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-A</
CloudFunction>
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
  <CloudFunctionConfiguration>
     <Id>2</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.png</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-B</
CloudFunction>
```

```
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
</NotificationConfiguration>
```

Your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes for the same event types. They can only do so, if the overlapping prefixes that are used with suffixes that don't overlap. The following example configuration shows how objects created with a common prefix but non-overlapping suffixes can be delivered to different destinations.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
     <Id>1</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images</Value>
                </FilterRule>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.jpg</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-A</
CloudFunction>
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
  <CloudFunctionConfiguration>
     <Id>2</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images</Value>
                </FilterRule>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.png</Value>
                </FilterRule>
            </S3Key>
     </Filter>
```

```
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-B</
CloudFunction>
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
</NotificationConfiguration>
```

Examples of notification configurations with invalid prefix and suffix overlapping

For the most part, your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes, overlapping suffixes, or overlapping combinations of prefixes and suffixes for the same event types. You can have overlapping prefixes as long as the suffixes don't overlap. For an example, see Configuring event notifications using object key name filtering.

You can use overlapping object key name filters with different event types. For example, you can create a notification configuration that uses the prefix `image/` for the `ObjectCreated:Put` event type and the prefix `image/` for the `ObjectRemoved:*` event type.

You get an error if you try to save a notification configuration that has invalid overlapping name filters for the same event types when using the Amazon S3 console or API. This section shows examples of notification configurations that aren't valid because of overlapping name filters.

Any existing notification configuration rule is assumed to have a default prefix and suffix that match any other prefix and suffix, respectively. The following notification configuration isn't valid because it has overlapping prefixes. Specifically, the root prefix overlaps with any other prefix. The same thing is true if you use a suffix instead of a prefix in this example. The root suffix overlaps with any other suffix.

```
<NotificationConfiguration>
     <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-notification-one</Topic>
         <Event>s3:ObjectCreated:*</Event>
    </TopicConfiguration>
    <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-notification-two</Topic>
         <Event>s3:ObjectCreated:*</Event>
         <Filter>
             <S3Key>
                 <FilterRule>
                     <Name>prefix</Name>
                     <Value>images</Value>
                 </FilterRule>
            </S3Key>
```

```
        </Filter>
    </TopicConfiguration>
</NotificationConfiguration>
```

The following notification configuration isn't valid because it has overlapping suffixes. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can end with `jpg` and `pg`. So, the suffixes overlap. The same is true for prefixes. If a given string can begin with both prefixes, the two prefixes are considered overlapping.

```
 <NotificationConfiguration>
     <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-one</Topic>
         <Event>s3:ObjectCreated:*</Event>
         <Filter>
             <S3Key>
                 <FilterRule>
                     <Name>suffix</Name>
                     <Value>jpg</Value>
                 </FilterRule>
            </S3Key>
        </Filter>
    </TopicConfiguration>
    <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-two</Topic>
         <Event>s3:ObjectCreated:Put</Event>
         <Filter>
             <S3Key>
                 <FilterRule>
                     <Name>suffix</Name>
                     <Value>pg</Value>
                 </FilterRule>
            </S3Key>
        </Filter>
    </TopicConfiguration>
</NotificationConfiguration
```

The following notification configuration isn't valid because it has overlapping prefixes and suffixes.

```
<NotificationConfiguration>
     <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-one</Topic>
         <Event>s3:ObjectCreated:*</Event>
```

```
        <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images</Value>
                </FilterRule>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>jpg</Value>
                </FilterRule>
            </S3Key>
        </Filter>
    </TopicConfiguration>
    <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-two</Topic>
         <Event>s3:ObjectCreated:Put</Event>
         <Filter>
             <S3Key>
                 <FilterRule>
                     <Name>suffix</Name>
                     <Value>jpg</Value>
                 </FilterRule>
             </S3Key>
         </Filter>
    </TopicConfiguration>
</NotificationConfiguration>
```

Event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format.

For a general overview and instructions on configuring event notifications, see Amazon S3 Event Notifications.

This example shows *version 2.6* of the event notification JSON structure. Previously, Amazon S3 used different versions for different event types. General events used version 2.1, cross-Region replication events used 2.2, and S3 Lifecycle, S3 Intelligent-Tiering, object ACL, object tagging, and object restoration delete events used version 2.3.

Starting with version 2.4, Amazon S3 uses a single unified version for all event types, and the version increments consistently across all event types whenever the schema evolves. Each event contains extra information specific to the operation.

The maximum size of an event notification message is 64 KB. When using Amazon SQS as a destination, we recommend that you set your queue's `MaximumMessageSize` attribute to at least 64 KB. If an event notification exceeds the queue's configured `MaximumMessageSize`, Amazon SQS rejects the notification and doesn't deliver the event. For more information, see Event notification types and destinations.

```
{
   "Records":[
      {
         "eventVersion":"2.6",
         "eventSource":"aws:s3",
         "awsRegion":"us-west-2",
         "eventTime":"The time, in ISO-8601 format (for example,
 1970-01-01T00:00:00.000Z) when Amazon S3 finished processing the request",
         "eventName":"The event type",
         "userIdentity":{
            "principalId":"The unique ID of the IAM resource that caused the event"
         },

               "eTag":"The object entity tag (ETag)",
```

```
                "versionId":"The object version if the bucket is versioning-enabled;
 null or not present if the bucket isn't versioning-enabled",
                "sequencer": "A string representation of a hexadecimal value used to
 determine event sequence; only used with PUT and DELETE requests"
             }
          },
          "glacierEventData": {
             "restoreEventData": {
                "lifecycleRestorationExpiryTime": "The time, in ISO-8601 format (for
 example, 1970-01-01T00:00:00.000Z), when the temporary copy of the restored object
 expires",
                "lifecycleRestoreStorageClass": "The source storage class for restored
 objects"
             }
          },
          "objectRetentionEventData": {
             "mode": "The Object Lock retention mode applied to the object: COMPLIANCE
 or GOVERNANCE",
             "retainUntilDate": "The date, in ISO-8601 format, until which the object is
 retained",
             "eventHold": "The event hold state after the change: ON or OFF; present for
 event-hold operations",
             "eventHoldDuration": "The event hold duration after the change, as {"days":
 N} or {"years": N}. Present when an event hold duration is set or modified."
          }
       }
    ]
}
```

Note the following about the event message structure:

- The `eventVersion` key value contains a major and minor version in the form *`major.minor`*.

  The major version is incremented if Amazon S3 makes a change to the event structure that's not backward compatible. This includes removing a JSON field that's already present or changing how the contents of a field are represented (for example, a date format).

  The minor version is incremented if Amazon S3 makes a backward-compatible change to the event structure. This includes adding new fields to the event structure or introducing new event types. To stay compatible with new minor versions of the event structure, we recommend that your applications ignore new fields.

To ensure that your applications can parse the event structure correctly, we recommend that you do an equal-to comparison on the major version number. To ensure that the fields that are expected by your application are present, we also recommend doing a greater-than-or-equal-to comparison on the minor version.

- The `eventName` key value references the list of event notification types but doesn't contain the `s3:` prefix.
- The `userIdentity` key value references the unique ID of the AWS Identity and Access Management (IAM) resource (a user, role, group, and so on) that caused the event. For a definition of each IAM identification prefix (for example, AIDA, AROA, AGPA) and information about how to get the unique identifier, see Unique identifiers in the *IAM User Guide*.
- The `responseElements` key value is useful if you want to trace a request by following up with AWS Support. Both `x-amz-request-id` and `x-amz-id-2` help Amazon S3 trace an individual request. These values are the same as those that Amazon S3 returns in the response to the request that initiates the events. Therefore, you can use these values to match the event to the request.
- The `s3` key value provides information about the bucket and object involved in the event. The object key name value is URL encoded. For example, `red flower.jpg` becomes `red +flower.jpg`. (Amazon S3 returns "`application/x-www-form-urlencoded`" as the content type in the response.)

  The `ownerIdentity` key value corresponds to the Amazon retail (Amazon.com) customer ID of the bucket owner. This ID value is no longer used and is maintained only for backward compatibility.
- The `sequencer` key value provides a way to determine the sequence of events. Event notifications aren't guaranteed to arrive in the same order that the events occurred. However, notifications from events that create objects (PUT requests) and delete objects contain a `sequencer`. You can use this value to determine the order of events for a given object key.

  If you compare the `sequencer` strings from two event notifications on the same object key, the event notification with the greater `sequencer` hexadecimal value is the event that occurred later. If you're using event notifications to maintain a separate database or index of your Amazon S3 objects, we recommend that you compare and store the `sequencer` values as you process each event notification.

  Note the following:

  - You can't use the `sequencer` key value to determine the order for events on different object keys.
  - The `sequencer` strings can be of different lengths. So, to compare these values, first left-pad the shorter value with zeros, and then do a lexicographical comparison.
- The `glacierEventData` key value is only visible for `s3:ObjectRestore:Completed` events.
- The `restoreEventData` key value contains attributes that are related to your restore request.
- The `replicationEventData` key value is only visible for replication events.
- The `intelligentTieringEventData` key value is only visible for S3 Intelligent-Tiering events.
- The `lifecycleEventData` key value is only visible for S3 Lifecycle transition events.
- The `objectAnnotation` key value is only visible for annotation events (`ObjectAnnotation:Put` and `ObjectAnnotation:Delete`). It contains an array with the annotation `name`, `size` (Put events only), and `eTag` (Put events only).
- For `ObjectCreated:Copy` events, the `object` block includes a `hasObjectAnnotation` boolean field that indicates whether the copied object has annotations.
- The `objectRetentionEventData` key value is only visible for Object Lock retention events (`ObjectRetention:Put`). It contains the object's Object Lock retention state after the change. The `mode` and `retainUntilDate` fields are always present. The `eventHold` field (`ON` or `OFF`) is present for event-hold operations, and `eventHoldDuration` is present when an event hold duration is set or modified.

Example messages

The following are examples of Amazon S3 event notification messages.

Amazon S3 test message

After you configure an event notification on a bucket, Amazon S3 sends the following test message.

```
{
   "Service":"Amazon S3",
   "Event":"s3:TestEvent",
   "Time":"2014-10-13T15:57:02.089Z",
   "Bucket":"amzn-s3-demo-bucket",
   "RequestId":"5582815E1AEA5ADF",
   "HostId":"8cLeGAmw098X5cv4Zkwcmo8vvZa3eH3eKxsPzbB9wrR+YstdA6Knx4Ip8EXAMPLE"
```

```
}
```

> **Note**
>
> The `s3:TestEvent` message uses a different format than regular S3 event notifications. Unlike other event notifications that use the `Records` array structure shown earlier, the test event uses a simplified format with direct fields. When implementing event handling, ensure your code can distinguish between and properly handle both message formats.

Example message when an object is created using a PUT request

The following is an example of a message that Amazon S3 sends to publish an `s3:ObjectCreated:Put` event.

```
{
   "Records":[
      {
         "eventVersion":"2.6",
         "eventSource":"aws:s3",
         "awsRegion":"us-west-2",
         "eventTime":"1970-01-01T00:00:00.000Z",
         "eventName":"ObjectCreated:Put",
         "userIdentity":{
            "principalId":"AIDAJDPLRKLG7UEXAMPLE"
         },
         "requestParameters":{
            "sourceIPAddress":"172.16.0.1"
         },
         "responseElements":{
            "x-amz-request-id":"C3D13FE58DE4C810",
            "x-amz-id-2":"FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvANOjpD"
         },
         "s3":{
            "s3SchemaVersion":"1.0",
            "configurationId":"testConfigRule",
            "bucket":{
               "name":"amzn-s3-demo-bucket",
               "ownerIdentity":{
                  "principalId":"A3NL1KOZZKExample"
               },
```

```
                "arn":"arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "object":{
                "key":"HappyFace.jpg",
                "size":1024,
                "eTag":"d41d8cd98f00b204e9800998ecf8427e",
                "versionId":"096fKKXTRTtl3on89fVO.nfljtsv6qko",
                "sequencer":"0055AED6DCD90281E5"
            }
         }
      }
   ]
}
```

Using EventBridge

Amazon S3 can send events to Amazon EventBridge whenever certain events happen in your bucket. Unlike other destinations, you don't need to select which event types you want to deliver. After EventBridge is enabled, all events below are sent to EventBridge. You can use EventBridge rules to route events to additional targets. The following lists the events Amazon S3 sends to EventBridge.

Event type	Description
Object Created	An object was created. The reason field in the event message structure indicates which S3 API was used to create the object: PutObject, POST Object, CopyObject, or CompleteMultipartUpload.
Object Deleted (DeleteObject) *Object Deleted (Lifecycle expiration)*	An object was deleted. When an object is deleted using an S3 API call, the reason field is set to DeleteObject. When an object is deleted by an S3 Lifecycle expiration rule, the reason field is set to Lifecycle Expiration. For more information, see Expiring objects. When an unversioned object is deleted, or a versioned object is permanently deleted, the deletion-type field

Event type	Description
	is set to Permanently Deleted. When a delete marker is created for a versioned object, the `deletion-type` field is set to Delete Marker Created. For more information, see Deleting object versions from a versioning-enabled bucket.
Object Restore Initiated	An object restore was initiated from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class or from S3 Intelligent-Tiering Archive Access or Deep Archive Access tier. For more information, see Working with archived objects.
Object Restore Completed	An object restore was completed.
Object Restore Expired	The temporary copy of an object restored from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive expired and was deleted.
Object Storage Class Changed	An object was transitioned to a different storage class. For more information, see Transitioning objects using Amazon S3 Lifecycle.
Object Access Tier Changed	An object was transitioned to the S3 Intelligent-Tiering Archive Access tier or Deep Archive Access tier. For more information, see Managing storage costs with Amazon S3 Intelligent-Tiering.
Object ACL Updated	An object's access control list (ACL) was set using `PutObjectAcl`. An event is not generated when a request results in no change to an object's ACL. For more information, see Access control list (ACL) overview.
Object Tags Added	A set of tags was added to an object using `PutObjectTagging`. For more information, see Tagging your objects.

Event type	Description
Object Tags Deleted	All tags were removed from an object using `DeleteObjectTagging`. For more information, see Tagging your objects.
Object Annotation Created	An annotation was created or updated on an object using `PutObjectAnnotation`. For more information, see Annotating your objects.
Object Annotation Removed	An annotation was deleted from an object using `DeleteObjectAnnotation`. For more information, see Annotating your objects.
Object Retention Updated	Amazon S3 sends this event when an object's Object Lock retention settings are changed through a `PutObjectRetention` request. This includes setting fixed or variable retention, releasing an event hold, modifying an event hold duration, and setting or extending a retain-until-date.

Note

For more information about how Amazon S3 event types map to EventBridge event types, see Amazon EventBridge mapping and troubleshooting.

You can use Amazon S3 Event Notifications with EventBridge to write rules that take actions when an event occurs in your bucket. For example, you can have it send you a notification. For more information, see What is EventBridge? in the *Amazon EventBridge User Guide*.

For more information about the actions and data types you can interact with using the EventBridge API, see the Amazon EventBridge API Reference in the *Amazon EventBridge API Reference*.

For information about pricing, see Amazon EventBridge pricing.

Topics

- Amazon EventBridge permissions

- Enabling Amazon EventBridge
- EventBridge event message structure
- Amazon EventBridge mapping and troubleshooting

Amazon EventBridge permissions

Amazon S3 does not require any additional permissions to deliver events to Amazon EventBridge.

Enabling Amazon EventBridge

You can enable Amazon EventBridge by using the S3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API.

> **Note**
>
> After you enable EventBridge, it takes around five minutes for the changes to take effect.

Using the S3 console

To enable EventBridge event delivery in the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and find the **Amazon EventBridge** subsection. Choose **Edit**.
6. Under **Send notifications to Amazon EventBridge for all events in this bucket** choose **On**.

Using the AWS CLI

The following example creates a bucket notification configuration for bucket *amzn-s3-demo-bucket1* with Amazon EventBridge enabled.

```
aws s3api put-bucket-notification-configuration --bucket amzn-s3-demo-bucket1 --
notification-configuration='{ "EventBridgeConfiguration": {} }'
```

Using the REST API

You can programmatically enable Amazon EventBridge on a bucket by calling the Amazon S3 REST API. For more information, see PutBucketNotificationConfiguration in the *Amazon Simple Storage Service API Reference*.

The following example shows the XML used to create a bucket notification configuration with Amazon EventBridge enabled.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <EventBridgeConfiguration>
  </EventBridgeConfiguration>
</NotificationConfiguration>
```

Creating EventBridge rules

Once enabled you can create Amazon EventBridge rules for certain tasks. For example, you can send email notifications when an object is created. For a full tutorial, see Tutorial: Send a notification when an Amazon S3 object is created in the *Amazon EventBridge User Guide*.

EventBridge event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format. When Amazon S3 sends an event to Amazon EventBridge, the following fields are present.

- `version` – Currently 0 (zero) for all events. This is an Amazon EventBridge envelope field and is not used for schema versioning. For event schema versioning, see the *event-version* field in the *detail* field.
- `id` – A UUID generated for every event.
- `detail-type` – The type of event that's being sent. See Using EventBridge for a list of event types.
- `source` – Identifies the service that generated the event.
- `account` – The 12-digit AWS account ID of the bucket owner.
- `time` – The time the event occurred.
- `region` – Identifies the AWS Region of the bucket.

- `resources` – A JSON array that contains the Amazon Resource Name (ARN) of the bucket.
- `detail` – A JSON object that contains information about the event. For more information about what can be included in this field, see Event message detail field.

Event message structure examples

The following are examples of some of the Amazon S3 event notification messages that can be sent to Amazon EventBridge.

Object created

```
{
  "version": "0",
  "id": "17793124-05d4-b198-2fde-7ededc63b103",

Event message detail field

The detail field contains a JSON object with information about the event. The following fields may be present in the detail field.

- `version` – Currently 0 (zero) for all events.
- `event-version` – The event schema version in the form *`major`*`.`*`minor`* (for example, `1.1`).

  The major version is incremented if Amazon S3 makes a change to the event structure that's not backward compatible. This includes removing a JSON field that's already present or changing how the contents of a field are represented (for example, a date format).

  The minor version is incremented if Amazon S3 makes a backward-compatible change to the event structure. This includes adding new fields to the event structure or introducing new event types. To stay compatible with new minor versions of the event structure, we recommend that your applications ignore new fields.

  To ensure that your applications can parse the event structure correctly, we recommend that you do an equal-to comparison on the major version number. To ensure that the fields that are expected by your application are present, we also recommend doing a greater-than-or-equal-to comparison on the minor version.
- `bucket` – Information about the Amazon S3 bucket involved in the event.
- `aws-generated-tags` – Tags attached to the bucket by AWS services. Only present when AWS generated tags exist on the bucket. This field is not present for cross-Region replication events.
- `object` – Information about the Amazon S3 object involved in the event.
- `request-id` – Request ID in S3 response.
- `requester` – AWS account ID or AWS service principal of requester.
- `source-ip-address` – Source IP address of S3 request. Only present for events triggered by an S3 request.
- `reason` – For **Object Created** events, the S3 API used to create the object: PutObject, POST Object, CopyObject, or CompleteMultipartUpload. For **Object Deleted** events, this is set to

DeleteObject when an object is deleted by an S3 API call, or **Lifecycle Expiration** when an object is deleted by an S3 Lifecycle expiration rule. For more information, see Expiring objects.

- `deletion-type` – For **Object Deleted** events, when an unversioned object is deleted, or a versioned object is permanently deleted, this is set to **Permanently Deleted**. When a delete marker is created for a versioned object, this is set to **Delete Marker Created**. For more information, see Deleting object versions from a versioning-enabled bucket.

> **Note**
>
> Some object attributes (such as `etag` and `size`) are present only when a delete marker is created.

- `restore-expiry-time` – For **Object Restore Completed** events, the time when the temporary copy of the object will be deleted from S3. For more information, see Working with archived objects.
- `source-storage-class` – For **Object Restore Initiated** and **Object Restore Completed** events, the storage class of the object being restored. For more information, see Working with archived objects.
- `destination-storage-class` – For **Object Storage Class Changed** events, the new storage class of the object. For more information, see Transitioning objects using Amazon S3 Lifecycle.
- `destination-access-tier` – For **Object Access Tier Changed** events, the new access tier of the object. For more information, see Managing storage costs with Amazon S3 Intelligent-Tiering.
- `object-annotation` – For **Object Annotation Created** and **Object Annotation Removed** events, the `detail` field includes an `object-annotation` field containing information about the annotation.
- `has-object-annotation` – For **Object Created** events with reason `CopyObject`, the `object` block includes a `has-object-annotation` boolean field that indicates whether the copied object has annotations.
- `object-retention-event-data` – For **Object Retention Updated** events, a block that contains the object's Object Lock retention state after the change. This block contains the following fields.
  - `mode` – The Object Lock retention mode applied to the object after the change: `COMPLIANCE` or `GOVERNANCE`.

- `retain-until-date` – The date in ISO-8601 format until which the object is retained after the change. For objects with an active event hold, this is the dynamically computed date at the time Amazon S3 processes the event.
- `event-hold` – The event hold state after the change: `ON` or `OFF`. Only present for event-hold operations (setting or releasing an event hold).
- `event-hold-duration` – The event hold duration as `{"days": N}` or `{"years": N}`. Only present when an event hold duration is set or modified.

Amazon EventBridge mapping and troubleshooting

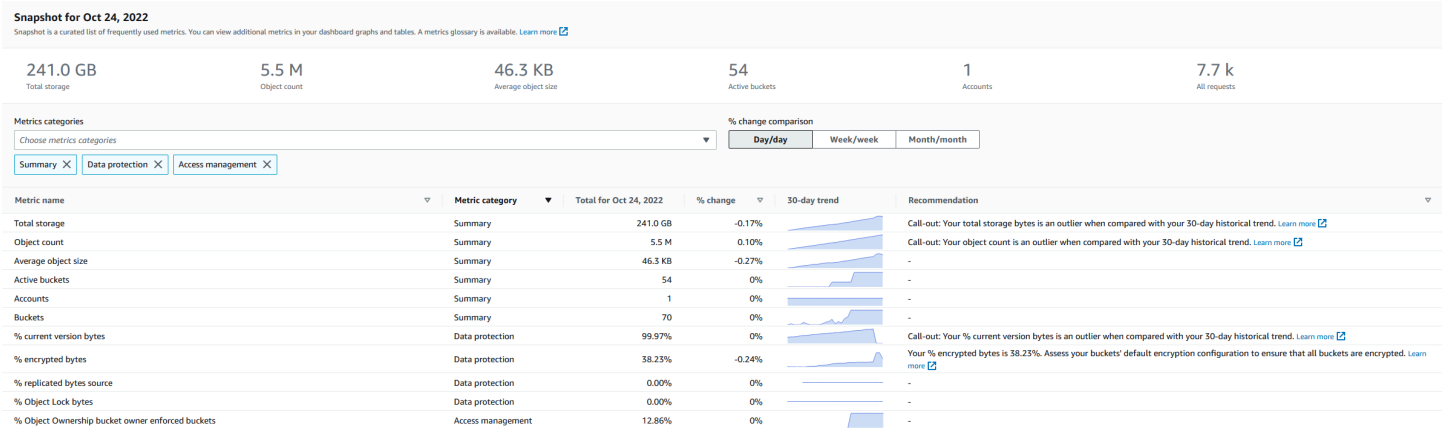
The following table describes how Amazon S3 event types are mapped to Amazon EventBridge event types.

S3 event type	Amazon EventBridge detail type
ObjectCreated:Put ObjectCreated:Post ObjectCreated:Copy ObjectCreated:CompleteMultipartUpload	Object Created
ObjectRemoved:Delete ObjectRemoved:DeleteMarkerCreated LifecycleExpiration:Delete LifecycleExpiration:DeleteMarkerCreated	Object Deleted
ObjectRestore:Post	Object Restore Initiated
ObjectRestore:Completed	Object Restore Completed
ObjectRestore:Delete	Object Restore Expired

S3 event type	Amazon EventBridge detail type
LifecycleTransition	Object Storage Class Changed
IntelligentTiering	Object Access Tier Changed
ObjectTagging:Put	Object Tags Added
ObjectTagging:Delete	Object Tags Deleted
ObjectAcl:Put	Object ACL Updated
ObjectAnnotation:Put	Object Annotation Created
ObjectAnnotation:Delete	Object Annotation Removed
ObjectRetention:Put	Object Retention Updated

Amazon EventBridge troubleshooting

For information about how to troubleshoot EventBridge, see Troubleshooting Amazon EventBridge in the *Amazon EventBridge User Guide*.



Monitoring your storage activity and usage with Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object storage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

You can use S3 Storage Lens metrics to generate summary insights. For example, you can find out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost optimization opportunities, implement data protection and access management best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules set up to expire incomplete multipart uploads that are more than 7 days old.

You can also identify buckets that aren't following data protection best practices, such as using S3 Replication or S3 Versioning.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

S3 Storage Lens metrics and features

S3 Storage Lens provides an interactive *default dashboard* that is updated daily. S3 Storage Lens preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. Metrics from this dashboard are also summarized in your account snapshot on the **Buckets** page. For more information, see Default dashboard.

To create other dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations), you create an S3 Storage Lens dashboard configuration. You can create and manage S3 Storage Lens dashboard configurations by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

S3 Storage Lens offers free tier metrics and advanced tier metrics, which you can upgrade to for an additional charge. With the advanced tier, you can access additional metrics and features for gaining insight into your storage. These features include advanced metric categories, prefix

aggregation, contextual recommendations, expanded prefixes metrics reports, and Amazon CloudWatch publishing. Prefix aggregation and contextual recommendations are available only in the Amazon S3 console. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

Metrics categories

Within the free and advanced tiers, metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to the advanced tier, you can enable advanced cost optimization and data protection metrics. You can use these advanced metrics to further reduce your S3 storage costs and improve your data protection stance. You can also enable activity metrics and detailed status-code metrics to improve the performance of application workloads that are accessing your S3 buckets. For more information about the free and advanced metrics categories, see Metrics selection.

You can assess your storage based on S3 best practices, such as analyzing the percentage of your buckets that have encryption or S3 Object Lock or S3 Versioning enabled. You can also identify potential cost-savings opportunities. For example, you can use S3 Lifecycle rule count metrics to identify buckets that are missing lifecycle expiration or transition rules. You can also analyze your request activity per bucket to find buckets where objects could be transitioned to a lower-cost storage class. For more information, see Amazon S3 Storage Lens metrics use cases.

Metrics export

Default metrics report

The default metrics report in S3 Storage Lens includes free metrics and advanced tier metrics covering object storage usage and activity trends across your AWS accounts. The report includes prefix aggregation for prefixes whose objects comprise at least 1% of the total data stored in the bucket, and supports up to 10 levels of prefix depth. The report can be exported daily in CSV or Parquet format to an S3 general purpose bucket. The report can also be sent to an AWS-managed S3 table bucket (with name `aws-s3`) making it easy to query using AWS analytics services or third-party tools.

With the default metrics report, you can identify cost optimization opportunities like buckets without S3 Lifecycle rules for incomplete multipart uploads and buckets not following data protection best practices such as S3 Replication or S3 Versioning. The default metrics report also provides contextual recommendations for optimizing storage costs and applying data protection best practices, at no additional charge beyond standard S3 storage costs.

Expanded prefixes metrics report

The Storage Lens expanded prefixes metrics report provides comprehensive prefix-level analytics across your entire S3 storage data, expanding coverage to support billions of prefixes in your bucket. This report delivers metrics for all prefixes in your buckets, including storage usage, bytes transferred, request counts by status code, and data protection compliance metrics, which you can export daily in CSV or Parquet format to S3 general purpose bucket. You can also export the metrics directly to the `aws-s3` AWS-managed S3 table bucket.

> **Note**
>
> The report processes metrics for prefixes up to 50 levels deep and excludes prefix-level metrics for any bucket where the prefix and storage class combinations exceed twice the object count.

With the expanded prefixes metrics report, you can identify performance optimization opportunities, such as high error rates, small objects, or sub-optimal request patterns, across billions of prefixes in your bucket. Unlike the default metrics report, the expanded prefixes metrics report delivers metrics for granular prefixes in your bucket. For example, you can identify prefixes with large numbers of objects of size less than 128KB to quickly isolate such datasets for compaction that will improve application performance. This report is available in all AWS Regions as an opt-in feature in the Storage Lens advanced tier dashboard configuration.

Metrics publishing

Amazon CloudWatch publishing

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. The CloudWatch publishing option is available for dashboards that are upgraded to the S3 Storage Lens advanced tier. For more information about support for S3 Storage Lens metrics in CloudWatch, see Monitor S3 Storage Lens metrics in CloudWatch.

For more information about using S3 Storage Lens, see the following topics.

Understanding Amazon S3 Storage Lens

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket. You can create and manage S3 Storage Lens dashboards by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

S3 Storage Lens concepts and terminology

This section contains the terminology and concepts that are essential for successfully understanding and using Amazon S3 Storage Lens.

Topics

- Dashboard configuration
- Default dashboard
- Dashboards
- Account snapshot
- Metrics export
- Metrics export destinations
- Home Region
- Retention period
- Metrics categories
- Recommendations
- Metrics selection
- Prefix delimiter
- S3 Storage Lens and AWS Organizations

Dashboard configuration

S3 Storage Lens requires a dashboard configuration that contains the properties required to aggregate metrics on your behalf for a single dashboard or export. When you create a

configuration, you choose the dashboard name and the home Region, which you can't change after you create the dashboard. You can optionally add tags and configure a metrics export in CSV or Parquet format.

In the dashboard configuration, you also define the dashboard scope and the metrics selection. The scope can include all the storage for your organization account or sections that are filtered by Region, bucket, and account. When you configure the metrics selection, you choose between free tier metrics and advanced tier metrics, which you can upgrade to for an additional charge. With the advanced tier, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

Default dashboard

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. S3 preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from free tier metrics to advanced tier metrics. You can configure the optional metrics export or even disable the dashboard. However, you can't delete the default dashboard.

> **Note**
>
> If you disable your default dashboard, it's no longer updated. You'll no longer receive any new daily metrics in your S3 Storage Lens dashboard, your metrics export, or the account snapshot on the S3 **Buckets** page. If your dashboard uses advanced metrics, you'll no longer be charged. You can still see historic data in the dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics. To access historic data, you can re-enable the dashboard within the expiration period.

Dashboards

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations). When you create or edit a S3 Storage Lens dashboard, you define your dashboard scope and metrics selection. S3 Storage Lens offers free tier metrics and advanced tier metrics, which you can upgrade to for an additional charge. With advanced metrics, you can access additional metrics and features for gaining insight into

your storage. These include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

You can also disable or delete dashboards. If you disable a dashboard, it's no longer updated, and you will no longer receive any new daily metrics. You can still see historic data until the 14-day expiration period. If you enabled advanced metrics for that dashboard, this period is 15 months. To access historic data, you can re-enable the dashboard within the expiration period.

If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

Note

- You can use S3 Storage Lens to create up to 50 dashboards per home Region.
- Organization-level dashboards can be limited only to a Regional scope.

Account snapshot

The S3 Storage Lens **Account snapshot** summarizes metrics from your default dashboard and displays your total storage, object count, and average object size on the S3 console **Buckets** page. This account snapshot gives you quick access to insights about your storage without having to leave the **Buckets** page. The account snapshot also provides one-click access to your interactive S3 Storage Lens dashboard.

You can use your dashboard to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate insights at the organization, account, bucket, object, or prefix level. You can also send a once-daily metrics export to an S3 bucket in CSV or Parquet format.

You can't modify the dashboard scope of the **default-account dashboard** because it's linked to the **Account snapshot**. However, you can upgrade the metrics selection in your **default-account-dashboard** from free metrics to paid advanced metrics. After upgrading, you can then display all requests, bytes uploaded, and bytes downloaded in the S3 Storage Lens **Account snapshot**.

> **Note**
>
> If you disable your default dashboard, your **Account snapshot** is no longer updated. To continue displaying metrics in the **Account snapshot**, you can re-enable the **default-account-dashboard**.

Metrics export

An S3 Storage Lens metrics export is a file that contains all the metrics identified in your S3 Storage Lens configuration. This information is generated daily in CSV or Parquet format and is sent to a general purpose S3 bucket. You can also export the metrics directly to the `aws-s3` AWS-managed S3 table bucket making it easy to query using AWS analytics services or third-party tools. You can use the metrics export for further analysis by using the metrics tool of your choice. The bucket specified for your metrics export must be in the same Region as your S3 Storage Lens configuration. You can generate an S3 Storage Lens metrics export from the S3 console by editing your dashboard configuration. You can also configure a metrics export by using the AWS CLI and AWS SDKs.

There are two types of metric exports available in Storage Lens:

- **Default metrics report** – The default metrics report in S3 Storage Lens includes free metrics and activity trends across your AWS account and aggregates usage metrics for top prefixes.
- **Expanded prefixes metrics report** – The Storage Lens expanded prefixes metrics report provides granular storage and activity metrics (such as storage usage, bytes transferred, and request counts by status code) at the prefix level for every prefix in your bucket. This report is available as an opt-in feature in all AWS Regions, through the advanced pricing tier in your Storage Lens dashboard configuration. For information about S3 Storage Lens feature pricing, see Amazon S3 pricing.

> **Note**
>
> Storage Lens only generates metrics for S3 general purpose buckets.

Metrics export destinations

When exporting Storage Lens metrics data, you can choose both an S3 general purpose bucket or an S3 table bucket as your destination. General purpose buckets provide broad compatibility with existing tools and applications, offering flexibility to process data within your account, using your preferred analytics services. This option supports standard S3 access patterns and integrations for data analysis within individual buckets in your Region. In contrast, S3 table bucket lets you run immediate queries across multiple accounts and regions, create custom dashboards with AWS Quick, and join data with other AWS services or third-party tools, without the need for additional processing infrastructure. For example, you can combine Storage Lens metrics with S3 Metadata to analyze object activity patterns across your organization.

S3 general purpose bucket

Exporting Storage Lens metrics to an S3 general purpose bucket offers flexibility and continuity for storing your Storage Lens data. You can maintain existing workflows and operational consistency by continuing to use your current infrastructure and existing extract, transform, and load (ETL) processes, analytics tools, or automated workflows. General purpose buckets also work with the full range of AWS services and third-party tools that support standard S3 APIs. This gives you maximum flexibility in how you process, analyze, or visualize your Storage Lens insights. Additionally, you can implement S3 lifecycle policies to automatically manage data retention, transitioning older metrics to lower-cost storage classes or deleting them after specified periods to optimize costs. Therefore, if operational continuity and workflow flexibility are your priorities for Storage Lens implementation, then consider choosing an S3 general purpose bucket for exporting your Storage Lens data. For more information about S3 general purpose buckets pricing, see Amazon S3 pricing.

S3 table bucket

When exporting Storage Lens metrics to S3 table bucket, you can easily analyze your storage usage and activity metrics without building data pipelines. Your metrics are organized in S3 Tables that are created in an AWS-managed S3 table bucket called `aws-s3` for optimal query performance, with customizable retention periods and encryption settings to meet your data management needs. With your metrics in S3 Tables, you can run queries across multiple accounts and Regions using SQL tools and AWS analytics services (like Amazon Athena, AWS Quick, Amazon EMR, and Amazon Redshift) to create custom dashboards and generate deeper insights. For example, you can join S3 Storage Lens metrics with S3 Metadata to identify objects in prefixes that aren't showing any recent activity. Any data stored in an S3 table bucket incurs S3 Tables costs. For more information about S3 Tables pricing, see Amazon S3 pricing.

Home Region

The home Region is the AWS Region where all S3 Storage Lens metrics for a given dashboard configuration are stored. You must choose a home Region when you create your S3 Storage Lens dashboard configuration. After you choose a home Region, you can't change it. Also, if you're creating a Storage Lens group, we recommend that you choose the same home Region as your Storage Lens dashboard.

Note

You can choose one of the following Regions as your home Region:

- US East (N. Virginia) – `us-east-1`
- US East (Ohio) – `us-east-2`
- US West (N. California) – `us-west-1`
- US West (Oregon) – `us-west-2`
- Asia Pacific (Mumbai) – `ap-south-1`
- Asia Pacific (Seoul) – `ap-northeast-2`
- Asia Pacific (Singapore) – `ap-southeast-1`
- Asia Pacific (Sydney) – `ap-southeast-2`
- Asia Pacific (Tokyo) – `ap-northeast-1`
- Canada (Central) – `ca-central-1`
- China (Beijing) – `cn-north-1`
- China (Ningxia) – `cn-northwest-1`
- Europe (Frankfurt) – `eu-central-1`
- Europe (Ireland) – `eu-west-1`
- Europe (London) – `eu-west-2`
- Europe (Paris) – `eu-west-3`
- Europe (Stockholm) – `eu-north-1`
- South America (São Paulo) – `sa-east-1`

Retention period

S3 Storage Lens metrics are retained so that you can see historical trends and compare differences in your storage and activity over time. You can use Amazon S3 Storage Lens metrics for queries so that you can see historical trends and compare differences in your storage usage and activity over time.

All S3 Storage Lens metrics are retained for a period of 15 months. However, metrics are only available for queries for a specific duration, which depends on your metrics selection. This duration can't be modified. Free metrics are available for queries for a 14-day period, and advanced metrics are available for queries for a 15-month period.

Metrics categories

Within the free and advanced tiers, S3 Storage Lens metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics, you can enable additional cost optimization and data protection metrics that you can use to further reduce your S3 storage costs and ensure your data is protected. You can also enable activity metrics and detailed status-code metrics that you can use to improve the performance of application workflows.

The following list shows all of the free and advanced metric categories. For a complete list of the individual metrics included in each category, see Amazon S3 Storage Lens metrics glossary.

Summary metrics

Summary metrics provide general insights about your S3 storage, including your total storage bytes and object count.

Cost optimization metrics

Cost optimization metrics provide insights that you can use to manage and optimize your storage costs. For example, you can identify buckets that have incomplete multipart uploads that are more than 7-days old.

With advanced metrics, you can enable advanced cost optimization metrics. These metrics include S3 Lifecycle rule count metrics that you can use to get per-bucket expiration and transition S3 Lifecycle rule counts.

Data-protection metrics

Data-protection metrics provide insights for data protection features, such as encryption and S3 Versioning. You can use these metrics to identify buckets that are not following data protection best practices. For example, you can identify buckets that are not using default encryption with AWS Key Management Service keys (SSE-KMS) or S3 Versioning.

With advanced metrics, you can enable advanced data protection metrics. These metrics include per-bucket replication rule count metrics.

Access management metrics

Access management metrics provide insights for S3 Object Ownership. You can use these metrics to see which Object Ownership settings your buckets use.

Event metrics

Event metrics provide insights for S3 Event Notifications. With event metrics, you can see which buckets have S3 Event Notifications configured.

Performance metrics

Performance metrics provide insights for S3 Transfer Acceleration. With performance metrics, you can see which buckets have Transfer Acceleration enabled.

Activity metrics (advanced)

If you upgrade your dashboard to the **Advanced tier**, you can enable activity metrics. Activity metrics provide details about how your storage is requested (for example, all requests, Get requests, Put requests), bytes uploaded or downloaded, and errors.

Prefix-level activity metrics can be used to help you determine which prefixes are being used infrequently, so that you can transition to a more optimal storage class using S3 Lifecycle.

Detailed status code metrics (advanced)

If you upgrade your dashboard to the **Advanced tier**, you can enable detailed status code metrics. Detailed status code metrics provide insights for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable, that you can use to troubleshoot access or performance issues. For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied.

Prefix-level detailed status code metrics can be used to gain a better understanding of the HTTP status code occurrences by prefix. For example, 503 error count metrics enable you to identify prefixes receiving throttling requests during data ingestion.

Advanced cost optimization metrics

Advanced cost optimization metrics provide detailed insights into your S3 lifecycle management configurations to help you optimize storage costs through automated data transitions and deletions. These metrics track the number of lifecycle rules configured across different lifecycle rule types. You can use these metrics to ensure comprehensive lifecycle rule coverage across your buckets and identify opportunities to implement additional cost optimization strategies through automated data management.

Advanced data protection metrics

Advanced data protection metrics help you protect your data by providing insights into replication rule counts, SSE-KMS encryption usage, and security vulnerabilities such as unsupported signature and TLS requests. (**Note:** Replication rule count metrics aren't available for prefixes.)

This visibility enables you to ensure proper data redundancy, validate encryption compliance, identify security risks from outdated protocols, troubleshoot replication misconfigurations, and maintain robust data protection strategies at the organization, account, and bucket levels.

Advanced performance metrics

Advanced performance metrics reveal how your applications interact with data in S3 and can help identify opportunities to optimize application performance such as inefficient I/O patterns, cross-region access, and unique object access count. Storage Lens advanced performance metrics eliminates the need for expensive custom monitoring tools and enables customers to implement S3 best practices more effectively, particularly benefiting performance sensitive applications such as machine learning training, data analytics, and other high-performance compute workloads.

Recommendations

S3 Storage Lens provides automated recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the S3 Storage Lens dashboard. Historical data is not eligible for recommendations because recommendations are relevant to what is happening in the most recent period. Recommendations appear only when they are relevant.

S3 Storage Lens recommendations come in the following forms:

- **Suggestions**

Suggestions alert you to trends within your storage and activity that might indicate a storage-cost optimization opportunity or a data protection best practice. You can use the suggested topics in the *Amazon S3 User Guide* and the S3 Storage Lens dashboard to drill down for more details about the specific Regions, buckets, or prefixes.

- **Call-outs**

  Call-outs are recommendations that alert you to interesting anomalies within your storage and activity over a period that might need further attention or monitoring.

  - **Outlier call-outs**

    S3 Storage Lens provides call-outs for metrics that are outliers, based on your recent 30-day trend. The outlier is calculated by using a standard score, also known as a *z-score*. In this score, the current day's metric is subtracted from the average of the last 30 days for that metric. The current day's metric is then divided by the standard deviation for that metric over the last 30 days. The resulting score is usually between -3 and +3. This number represents the number of standard deviations that the current day's metric is from the mean.

    S3 Storage Lens considers metrics with a score >2 or <-2 to be outliers because they are higher or lower than 95 percent of normally distributed data.

  - **Significant change call-outs**

    The significant change call-out applies to metrics that are expected to change less frequently. Therefore, it's set to a higher sensitivity than the outlier calculation, which is typically in the range of +/- 20 percent versus the prior day, week, or month.

    Addressing call-outs in your storage and activity – If you receive a significant change call-out, it’s not necessarily a problem. The call-out could be the result of an anticipated change in your storage. For example, you might have recently added a large number of new objects, deleted a large number of objects, or made similar planned changes.

    If you see a significant change call-out on your dashboard, take note of it and determine whether it can be explained by recent circumstances. If not, use the S3 Storage Lens dashboard to drill down for more details to understand the specific Regions, buckets, or prefixes that are driving the fluctuation.

- **Reminders**

Reminders provide insights into how Amazon S3 works. They can help you learn more about ways to use S3 features to reduce storage costs or apply data protection best practices.

Metrics selection

S3 Storage Lens offers two metrics selections that you can choose for your dashboard and export: *free tier* and *advanced tier*.

- **Free tier**

  S3 Storage Lens offers free metrics for all dashboards and configurations. Free metrics contain metrics that are relevant to your storage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics (for example, cost optimization and data protection metrics) that you can use to investigate whether your storage is configured according to S3 best practices. All free tier metrics are collected daily and can be exported to either an S3 general purpose bucket (CSV or Parquet format) or S3 table bucket (Parquet format only). Data is available for queries for 14 days in the Amazon S3 console. For more information about which metrics are available with free metrics, see the Amazon S3 Storage Lens metrics glossary.

- **Advanced tier**

  S3 Storage Lens offers free metrics for all dashboards and configurations with the option to upgrade to advanced metrics. Additional charges apply. For more information, see Amazon S3 pricing.

  Advanced tier metrics include all the metrics in free metrics along with additional metrics, such as advanced data protection and cost optimization metrics, activity metrics, and detailed status-code metrics. Advanced tier metrics also provide recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the dashboard.

  Advanced tier includes the following features:

  - **Advanced metrics categories** – Generate additional metrics. For a complete list of advanced metric categories, see Metrics categories. For a complete list of metrics, see the Amazon S3 Storage Lens metrics glossary.
  - **Amazon CloudWatch publishing** – Publishes S3 Storage Lens metrics to CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch API operations and features, such as alarms and triggered actions, metric math,

and anomaly detection, to monitor and take action on S3 Storage Lens metrics. For more information, see Monitor S3 Storage Lens metrics in CloudWatch.

- **Default metrics report** – The default metrics report in S3 Storage Lens includes free metrics and prefix aggregation capabilities for top prefixes for object storage usage and activity trends across your AWS accounts. With the default metrics report, you can identify cost optimization opportunities at no additional charge beyond standard S3 storage costs.
- **Expanded prefixes metrics report** – The Storage Lens expanded prefixes metrics report provides comprehensive prefix-level analytics across your entire S3 storage data, expanding coverage to support up to billions of prefixes per bucket.
- **Additional metrics aggregation**
  - **Prefix aggregation** – Collects metrics at the prefix level. This setting specifies the prefixes aggregated as part of the default metrics report, which is displayed in the Storage Lens dashboard. Note that metrics that are applicable at the prefix level are available with **Prefix aggregation**, except for bucket-level settings and rule count metrics. Prefix-level metrics don't apply to the expanded prefixes metrics export and aren't published to CloudWatch.
  - **Storage Lens group aggregation** – Collects metrics at the Storage Lens group level. After you enable the advanced tier metrics and Storage Lens group aggregation, you can specify which Storage Lens groups to include or exclude from your Storage Lens dashboard. At least one Storage Lens group must be specified. Storage Lens groups that are specified must also reside within the designated home Region in the dashboard account. Storage Lens group-level metrics are not published to CloudWatch.

All advanced metrics are collected daily. Data is available for querying for up to 15 months in the Amazon S3 console. For more information about the storage metrics that are aggregated by S3 Storage Lens, see Amazon S3 Storage Lens metrics glossary.

Prefix delimiter

Prefix delimiters determine how Storage Lens counts prefix depth, by separating the hierarchical levels within object keys. You can only specify a single character to indicate each level within your prefixes. If the prefix delimiter is undefined, Amazon S3 uses "/" as the default delimiter.

> **Note**
>
> When you're updating your Storage Lens dashboard configuration through the API, the *delimiter* and the updated *prefix delimiter* must be defined in the same way, or you'll

receive an error. The delimiter only applies to prefix-level metrics that are exported to the default metrics report. The prefix delimiter applies to all prefixes that are exported to the expanded prefixes metrics report.

S3 Storage Lens and AWS Organizations

AWS Organizations is an AWS service that helps you aggregate all of your AWS accounts under one organization hierarchy. Amazon S3 Storage Lens works with AWS Organizations to provide a single view of object storage and activity across your Amazon S3 storage.

For more information, see Using Amazon S3 Storage Lens with AWS Organizations.

- **Trusted access**

  Using your organization's management account, you must enable trusted access for S3 Storage Lens to aggregate storage metrics and usage data for all member accounts in your organization. You can then create dashboards or exports for your organization by using your management account or by giving delegated administrator access to other accounts in your organization.

  You can disable trusted access for S3 Storage Lens at any time, which stops S3 Storage Lens from aggregating metrics for your organization.

- **Delegated administrator**

  You can create dashboards and metrics for S3 Storage Lens for your organization by using your AWS Organizations management account, or by giving *delegated administrator* access to other accounts in your organization. You can deregister delegated administrators at any time. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

For more information, see Amazon S3 Storage Lens and AWS Organizations in the *AWS Organizations User Guide*.

Amazon S3 Storage Lens service-linked roles

Along with AWS Organizations trusted access, Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that's linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens

and include all the permissions that it requires to collect daily storage and activity metrics from member accounts in your organization.

For more information, see Using service-linked roles for Amazon S3 Storage Lens.

Amazon S3 Storage Lens metrics glossary

The Amazon S3 Storage Lens metrics glossary provides a complete list of free and advanced metrics for S3 Storage Lens.

S3 Storage Lens offers free metrics for all dashboards and configurations, with the option to upgrade to advanced metrics.

- **Free metrics** contain metrics that are relevant to your storage usage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics, such as cost-optimization and data-protection metrics. All free metrics are collected daily, and data is available for queries for up to 14 days.
- **Advanced metrics** include all the metrics in free metrics along with additional metrics, such as advanced performance, advanced data protection, and advanced cost optimization metrics. Advanced metrics also include additional metric categories, such as activity metrics and detailed status-code metrics. Advanced metrics data is available for queries for 15 months.

  There are additional charges when you use S3 Storage Lens with advanced metrics and recommendations. For more information, see Amazon S3 pricing. For more information about advanced metrics and recommendations features, see Metrics selection.

> **Note**
>
> For Storage Lens groups, only free tier storage metrics are available. Advanced tier metrics are not available at the Storage Lens group level.

Metric names

The **Metric name** column in the following table provides the name of each S3 Storage Lens in the S3 console. The **CloudWatch and export** column provides the name of each metric in Amazon CloudWatch and the metrics export file that you can configure in your S3 Storage Lens dashboard.

Derived metric formulas

Derived metrics are not available for the metrics export and the CloudWatch publishing option. However, you can use the metrics formulas shown in the **Derived metrics formula** column to compute them.

Interpreting the Amazon S3 Storage Lens prefix symbols for metrics unit multiples (K, M, G, and so on)

S3 Storage Lens metrics unit multiples are written with prefix symbols. These prefix symbols match the International System of Units (SI) symbols that are standardized by the International Bureau of Weights and Measures (BIPM). These symbols are also used in the Unified Code for Units of Measure (UCUM). For more information, see List of SI prefix symbols.

Note

- The unit of measurement for S3 storage bytes is in binary gigabytes (GB), where 1 GB is 2^{30} bytes, 1 TB is 2^{40} bytes, and 1 PB is 2^{50} bytes. This unit of measurement is also known as a gibibyte (GiB), as defined by the International Electrotechnical Commission (IEC).
- When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. S3 Storage Lens doesn't include metrics for objects that have expired but haven't been removed. For more information about expiration actions in S3 Lifecycle, see Expiring objects.
- Amazon S3 stores metadata (object key, timestamps, etc.) for every object, which requires minimum storage even for 0KB data files. This is why 0KB objects appear in the (0KB-128KB] size range in S3 Storage Lens.
- S3 Storage Lens provides best-effort tracking of cross-region data transfers, primarily focusing on requests from customer-managed resources like EC2 instances. Requests made through AWS PrivateLink or certain in-Region requests are unclassified.

The following table shows the S3 Storage Lens metrics glossary.

Metric name	CloudWatch and export	Description	Tier	Cate	D	Deri met forn	Storage Lens groups
Total storage	StorageBytes	Total storage, inclusive of incomplet e multipart uploads, object metadata, and delete markers	Free	Sum	N	-	Y
Object count	ObjectCount	Total number of objects inclusive of current version, noncurren t versions, incomplet e multipart uploads, and delete markers	Free	Sum	N	-	Y
Average object size	-	Average object size	Free	Sum	Y	sum geBy sum tCou	Y
Active buckets	-	Number of buckets with storage > 0 bytes	Free	Sum	Y	-	Y
Buckets	-	Number of buckets	Free	Sum	Y	-	Y
Accounts	-	Number of accounts whose	Free	Sum	Y	-	Y

Metric name	CloudWatch and export	Description	Tier	Cate	D	Deri met form	Storage Lens groups
		storage is in scope					
Current version bytes	CurrentVersionStorageBytes	Number of bytes that are a current version of an object	Free	Cost optimization	N	-	Y

Setting Amazon S3 Storage Lens permissions

Amazon S3 Storage Lens requires new permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to enable or disable S3 Storage Lens, or to access any S3 Storage Lens dashboard or configuration.

The IAM user or role must belong to the account that created or owns the dashboard or configuration, unless both of the following conditions are true:

- Your account is a member of AWS Organizations.
- You were given access to create organization-level dashboards by your management account as a delegated administrator.

Note

- You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required IAM permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see Security best practices in IAM in the *IAM User Guide*.
- Using S3 Storage Lens on the Amazon S3 console can require multiple permissions. For example, to edit a dashboard on the console, you need the following permissions:
  - `s3:ListStorageLensConfigurations`
  - `s3:GetStorageLensConfiguration`
  - `s3:PutStorageLensConfiguration`

Topics

- Setting account permissions to use S3 Storage Lens
- Setting account permissions to use S3 Storage Lens groups
- Setting permissions to use S3 Storage Lens with AWS Organizations

Setting account permissions to use S3 Storage Lens

To create and manage S3 Storage Lens dashboards and Storage Lens dashboard configurations, you must have the following permissions, depending on which actions you want to perform:

The following table shows Amazon S3 Storage Lens related IAM permissions.

Action	IAM permissions

Create or update an S3 Storage Lens dashboard in the Amazon S3 console.	`s3:ListStorageLensConfigurations`
	`s3:GetStorageLensConfiguration`
	`s3:GetStorageLensConfigurationTagging`
	`s3:PutStorageLensConfiguration`
	`s3:PutStorageLensConfigurationTagging`

Get the tags of an S3 Storage Lens dashboard on the Amazon S3 console.	`s3:ListStorageLensConfigurations` `s3:GetStorageLensConfigurationTagging`

View an S3 Storage Lens dashboard on the Amazon S3 console.	`s3:ListStorageLensConfigurations`
	`s3:GetStorageLensConfiguration`
	`s3:GetStorageLensDashboard`

Delete an S3 Storage Lens dashboard on Amazon S3 console.	`s3:ListStorageLensConfigurations`
	`s3:GetStorageLensConfiguration`
	`s3:DeleteStorageLensConfiguration`

Create or update an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	`s3:PutStorageLensConfiguration`

Action	IAM permissions
	`s3:PutStorageLensConfigurationTagging`
Get the tags of an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	`s3:GetStorageLensConfigurationTagging`
View an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	`s3:GetStorageLensConfiguration`
Delete an S3 Storage Lens configuration by using the AWS CLI or AWS SDK.	`s3:DeleteStorageLensConfiguration`

Note

- You can use resource tags in an IAM policy to manage permissions.
- An IAM user or role with these permissions can see metrics from buckets and prefixes that they might not have direct permission to read or list objects from.
- For S3 Storage Lens dashboards with prefix-level metrics enabled, if a selected prefix path matches with an object key, the dashboard might display the object key as another prefix.
- For metrics exports, which are stored in a bucket in your account, permissions are granted by using the existing `s3:GetObject` permission in the IAM policy. Similarly, for an AWS Organizations entity, the organization's management account or delegated administrator accounts can use IAM policies to manage access permissions for organization-level dashboard and configurations.

Setting account permissions to use S3 Storage Lens groups

You can use S3 Storage Lens groups to understand the distribution of your storage within buckets based on prefix, suffix, object tag, object size, or object age. You can attach Storage Lens groups to your dashboards to view their aggregated metrics.

To work with Storage Lens groups, you need certain permissions. For more information, see the section called “Storage Lens groups permissions”.

Setting permissions to use S3 Storage Lens with AWS Organizations

You can use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. The following table shows the actions and permissions related to using S3 Storage Lens with Organizations.

Action	IAM Permissions
Enable trusted access for S3 Storage Lens for your organization.	`organizations:EnableAWSServiceAccess`
Disable trusted access for S3 Storage Lens for your organization.	`organizations:DisableAWSServiceAccess`
Register a delegated administrator to create S3 Storage Lens dashboards or configurations for your organization.	`organizations:RegisterDelegatedAdministrator`
Deregister a delegated administrator so that they can no longer create S3 Storage Lens dashboards or configurations for your organization.	`organizations:DeregisterDelegatedAdministrator`

Additional permissions to create S3 Storage Lens organization-wide configurations.	`organizations:DescribeOrganization`
	`organizations:ListAccounts`
	`organizations:ListAWSServiceAccessForOrganization`
	`organizations:ListDelegatedAdministrators`
	`iam:CreateServiceLinkedRole`

Working with Amazon S3 Storage Lens by using the console and API

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

> **Note**
>
> Storage Lens only aggregates metrics for S3 general purpose buckets.

The following sections contain examples of creating, updating, and viewing S3 Storage Lens configurations and performing operations related to the feature. If you are using S3 Storage Lens with AWS Organizations, these examples also cover those use cases. In the examples, replace any placeholder values.

Topics

- Create an Amazon S3 Storage Lens dashboard
- Update an Amazon S3 Storage Lens dashboard
- Disable an Amazon S3 Storage Lens dashboard

- Delete an Amazon S3 Storage Lens dashboard
- List Amazon S3 Storage Lens dashboards
- View an Amazon S3 Storage Lens dashboard configuration details
- Managing AWS resource tags with S3 Storage Lens
- Helper files for using Amazon S3 Storage Lens

Create an Amazon S3 Storage Lens dashboard

You can create additional S3 Storage Lens custom dashboards that can be scoped to your organization in AWS Organizations or to specific AWS Regions or buckets within an account.

> **Note**
>
> Any updates to your dashboard configuration can take up to 48 hours to accurately display or visualize.

Using the S3 console

Use the following steps to create an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Configure general settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, under **S3 Storage Lens**, choose **Dashboards**.
4. Choose **Create dashboard**.
5. On the **Dashboard** page, in the **General** section, do the following:
    a. View the **Home Region** for your dashboard. The home Region is the AWS Region where the configuration and metrics for this Storage Lens dashboard are stored.
    b. Enter a dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces.

> **Note**
>
> You can't change this dashboard name after the dashboard is created.

c. Choose **Enabled** to display updated daily metrics in your dashboard.

d. (Optional) You can choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens. For more information, see Controlling access to AWS resources using tags in the *IAM User Guide* and Using AWS-generated tags in the *AWS Billing User Guide*.

> **Note**
>
> You can add up to 50 tags to your dashboard configuration.

6. Choose **Next** to save your changes and proceed.

Step 2: Define the dashboard scope

1. In the **Dashboard scope** section, choose the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.
2. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option isn't available when you create organization-level dashboards.

> **Note**
>
> - You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
> - You can choose up to 50 buckets to include or exclude.

3. Choose **Next** to save your changes and proceed.

Step 3: Choose your Storage Lens tier

1. In the **Storage Lens tier** section, choose the tier of features that you want to aggregate for this dashboard.

   a. To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free tier**.

   b. To enable advanced metrics, choose **Advanced tier**. These options include prefix or Storage Lens groups aggregation, Amazon CloudWatch publishing, the expanded prefixes report, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see Amazon S3 pricing.

   For more information about advanced metrics and free metrics, see Metrics selection.

2. Under **Advanced metric categories**, select the category of metrics that you want to enable:

   - **Activity metrics**
   - **Detailed status code metrics**
   - **Cost optimization metrics**
   - **Data protection metrics**
   - **Performance metrics**

   To preview which metrics are included in each category, use the drop-down arrow button below the metrics category checkbox list. For more information about metrics categories, see Metrics categories. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

3. Choose or specify a **Prefix delimiter** to distinguish levels within each prefix. This value is used to identify each prefix level. The default value in Amazon S3 is the "/" character, but your storage structure might use other delimiter characters.

4. Choose **Next** to save your changes and proceed.

Step 4: (Optional) Choose your metrics aggregation

1. Under **Additional metrics aggregation**, choose which metrics you want to aggregate:

   - Prefix aggregation

- Storage Lens group aggregation

2. If you've enabled **Prefix aggregation**, specify the minimum **Prefix threshold** for your dashboard and **Prefix depth**. Then, choose **Next** to save and proceed.

> **Note**
>
> The **Prefix depth** setting determines how many hierarchical levels deep S3 Storage Lens will analyze your object prefixes, with a maximum limit of 10 levels. The **Prefix threshold** specifies the minimum percentage of total storage that a prefix must represent before it's included in Storage Lens metrics.

3. If you've enabled **Storage Lens group aggregation**, choose one of the following:

- **Include Storage Lens groups**
- **Exclude Storage Lens groups**

4. When you include Storage Lens groups in your aggregation, you can either **Include all Storage Lens groups in your home Region** or specify Storage Lens groups to include.
5. Choose **Next** to save your changes and proceed.

Step 5: (Optional) Choose your metrics export and publishing settings

1. Under **Metrics publishing**, choose **CloudWatch publishing** if you want to access your Storage Lens metrics in your CloudWatch dashboard.

> **Note**
>
> Prefix-level metrics aren't available in CloudWatch.

2. Under **Metrics export**, choose which Storage Lens dashboard data you want exported daily:

- **Default metrics report**
- **Expanded prefixes metrics report**

3. (Optional) If you chose **Default metrics report**, in the **Default metrics report** settings, choose the bucket type. You can export the report to either a general purpose Amazon S3 bucket or AWS-managed S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings** options.

> **Note**
>
> The **default metrics report** only includes prefixes within the set threshold and depth set in prefix aggregation settings.
> If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see Using an AWS KMS key to encrypt your metrics exports.

4. (Optional) If you chose **Expanded prefixes metrics report**, in the **Expanded prefixes metrics report** settings, choose the bucket type. You can export the report to either a general purpose Amazon S3 bucket or a read-only S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings**.

> **Note**
>
> The **Expanded prefixes metrics report** includes all prefixes up to prefix depth 50 in all selected buckets that are specified in your dashboard scope.
> If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see Using an AWS KMS key to encrypt your metrics exports.

5. Choose **Next** to save your changes and proceed.
6. Review everything on the **Review and Create** page. If there are no additional changes, choose **Next** to save your changes and to create your dashboard.

Step 6: Review your dashboard configuration and create your dashboard

1. In the **General** section, review your settings. Choose **Edit** to make any changes.
2. In the **Dashboard scope** section, review your settings. Choose **Edit** to make any changes.
3. In the **Storage Lens tier** section, review your settings. Choose **Edit** to make any changes.
4. In the **Metrics aggregation** section, review your settings. Choose **Edit** to make any changes.

5. In the **Metrics export** section, review your settings. Choose **Edit** to make any changes.
6. After reviewing and confirming all your dashboard configuration settings, choose **Submit** to create your dashboard.

After you've successfully created your new Storage Lens dashboard, you can view your new dashboard listed under your Storage Lens **Dashboard** page.

Using the AWS CLI

Example

The following example command creates a Amazon S3 Storage Lens configuration with tags. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-
configuration=file://./config.json --tags=file://./tags.json
```

Example

The following example command creates a Amazon S3 Storage Lens configuration without tags. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=222222222222 --config-
id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./
config.json
```

Using the AWS SDK for Java

Example– Create and update an Amazon S3 Storage Lens configuration

The following example creates and updates an Amazon S3 Storage Lens configuration in SDK for Java:

```
package aws.example.s3control;

import software.amazon.awssdk.awscore.exception.AwsServiceException;
import software.amazon.awssdk.core.exception.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.AccountLevel;
import software.amazon.awssdk.services.s3control.model.ActivityMetrics;
import software.amazon.awssdk.services.s3control.model.AdvancedCostOptimizationMetrics;
import software.amazon.awssdk.services.s3control.model.AdvancedDataProtectionMetrics;
import software.amazon.awssdk.services.s3control.model.AdvancedPerformanceMetrics;
import software.amazon.awssdk.services.s3control.model.BucketLevel;
import software.amazon.awssdk.services.s3control.model.CloudWatchMetrics;
import software.amazon.awssdk.services.s3control.model.DetailedStatusCodesMetrics;
import software.amazon.awssdk.services.s3control.model.Format;
import software.amazon.awssdk.services.s3control.model.Include;
import software.amazon.awssdk.services.s3control.model.OutputSchemaVersion;
import software.amazon.awssdk.services.s3control.model.PrefixLevel;
import software.amazon.awssdk.services.s3control.model.PrefixLevelStorageMetrics;
import
 software.amazon.awssdk.services.s3control.model.PutStorageLensConfigurationRequest;
import software.amazon.awssdk.services.s3control.model.S3BucketDestination;
import software.amazon.awssdk.services.s3control.model.SSES3;
import software.amazon.awssdk.services.s3control.model.SelectionCriteria;
import software.amazon.awssdk.services.s3control.model.StorageLensAwsOrg;
import software.amazon.awssdk.services.s3control.model.StorageLensConfiguration;
import software.amazon.awssdk.services.s3control.model.StorageLensDataExport;
import software.amazon.awssdk.services.s3control.model.StorageLensDataExportEncryption;
import
 software.amazon.awssdk.services.s3control.model.StorageLensExpandedPrefixesDataExport;
import software.amazon.awssdk.services.s3control.model.StorageLensTableDestination;
import software.amazon.awssdk.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

public class CreateAndUpdateDashboard {

            );

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();

 s3ControlClient.putStorageLensConfiguration(PutStorageLensConfigurationRequest.builder()
                    .accountId(sourceAccountId)
                    .configId(configurationId)
                    .storageLensConfiguration(configuration)
                    .tags(tags)
                    .build()
            );

        } catch (AwsServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

For access to S3 Storage Lens groups or expanded prefixes, you must upgrade your dashboard to use the advanced tier. Additional charges apply. For more information about the free and advanced tiers, see Metrics selection. For more information about S3 Storage Lens groups, see the section called “Working with Storage Lens groups”.

Update an Amazon S3 Storage Lens dashboard

The Amazon S3 Storage Lens default dashboard is `default-account-dashboard`. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export, or even disable the default dashboard. The default dashboard can't be deleted, and can only be disabled. For more information, see Using the S3 console.

Using the S3 console

Use the following steps to update an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Update your dashboard and configure your general settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit.
4. Choose **View dashboard configuration**.
5. Choose **Edit**. You can now review the dashboard configuration, step by step. To make changes to any of the steps, you can choose the step directly using the left navigation. For instructions on how to update those steps,

   > **Note**
   >
   > You can't change the following:
   >
   > - The dashboard name
   > - The home Region

6. On the **Dashboard** page, in the **General** section, you can make changes to the following:

   - Choose **Enabled** or **Disabled** to update whether you're receiving daily metrics in your dashboard.

- (Optional) You can choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens. For more information, see Controlling access to AWS resources using tags in the *IAM User Guide* and Using AWS-generated tags in the *AWS Billing User Guide*.

> **Note**
>
> You can add up to 50 tags to your dashboard configuration.

7. Choose **Next** to save your changes and proceed.

Step 2: Update the dashboard scope

1. In the **Dashboard scope** section, update the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.

> **Note**
>
> - You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
> - You can choose up to 50 buckets to include or exclude.

2. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option isn't available when you create organization-level dashboards.

> **Note**
>
> - You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
> - You can choose up to 50 buckets to include or exclude.

3. Choose **Next** to save your changes and proceed.

Step 3: Update your Storage Lens tier Configure the metrics selection

1. In the **Storage Lens tier Metrics selection** section, update the tier of metrics that you want to aggregate for this dashboard.

   > **Note**
   >
   > - If you're updating from the **Free tier** to the **Advanced tier**, you'll need to update your **Metrics aggregation** settings. To update your **Metrics aggregation settings**, see **Step 4: Update your metrics aggregation**.
   > - If you're updating your Storage Lens tier from the **Advanced tier** to the **Free tier**, you won't need to update any **Metrics aggregation** settings. The **Metrics aggregation** feature only applies to **Advanced tier** metric categories.

2. To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free tier**.
3. To enable advanced metrics, choose **Advanced tier**. These options include prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see Amazon S3 pricing.

   For more information about advanced metrics and free metrics, see Metrics selection.
4. Under **Advanced metric categories**, choose the category of metrics that you want to enable:

   - **Activity metrics**
   - **Detailed status code metrics**
   - **Cost optimization metrics**
   - **Data protection metrics**
   - **Performance metrics**

   To preview which metrics are included in each category, use the drop-down arrow button below the metrics category checkbox list. For more information about metrics categories, see Metrics categories. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

5. Choose or specify a **Prefix delimiter** to distinguish levels within each prefix. This value is used to identify each prefix level. The default value in Amazon S3 is the "/" character, but your storage structure might use other delimiter characters.
6. Choose **Next** to save your changes and proceed.

Step 4: (Optional) Update your metrics aggregation

1. Under **Additional metrics aggregation**, update which metrics you want to aggregate by choosing one of the following:
   - Prefix aggregation
   - Storage Lens group aggregation
2. If you've enabled **Prefix aggregation**, specify the minimum **Prefix threshold** for your dashboard and **Prefix depth**. Then, choose **Next** to save and proceed.
3. If you've enabled **Storage Lens group aggregation**, choose one of the following:
   - **Include Storage Lens groups**
   - **Exclude Storage Lens groups**
4. When you include Storage Lens groups in your aggregation, you can either **Include all Storage Lens groups in your home Region** or specify Storage Lens groups to include.
5. Choose **Next** to save your changes and proceed.

Step 5: (Optional) Update your metrics export and publishing settings

1. Under **Metrics publishing**, choose **CloudWatch publishing** if you want to access your Storage Lens metrics in your CloudWatch dashboard.

   > **Note**
   >
   > Prefix-level metrics aren't available in CloudWatch.

2. Under **Metrics export**, choose which Storage Lens dashboard data you want exported daily:
   - **Default metrics report**
   - **Expanded prefixes metrics report**

3. (Optional) If you chose **Default metrics report**, in the **Default metrics report** settings, choose the bucket type. You can export the report to either a general purpose S3 bucket or a read-only S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings** options.

   Note

   - The **default metrics report** only includes prefixes within the set threshold and depth set in prefix aggregation settings. If your prefix aggregation isn't already configured, the threshold includes up to the 100 largest prefixes by size.
   - If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see Using an AWS KMS key to encrypt your metrics exports.

4. Choose **Next** to save your changes and proceed.

5. (Optional) If you chose **Expanded prefixes metrics report**, in the **Expanded prefixes metrics report** settings, choose the bucket type. You can export the report to either a general purpose S3 bucket or a read-only S3 table bucket. Based on the selected bucket type, update the **General purpose bucket destination settings** or **Table bucket destination settings**.

   Note

   - The **Expanded prefixes metrics report** includes prefixes in all buckets that are specified in your dashboard scope.
   - If you choose to specify an encryption key, you must choose an AWS KMS key (SSE-KMS) or Amazon S3 managed key (SSE-S3). If your destination bucket policy requires encryption, you must provide an encryption key for your metrics export. Without the encryption key, the export to S3 fails. For more information, see Using an AWS KMS key to encrypt your metrics exports.

6. Choose **Next** to save your changes and proceed.

Step 6: Review and update your dashboard configuration

1. In the **General** section, review your settings. Choose **Edit** to make any changes.
2. In the **Dashboard scope** section, review your settings. Choose **Edit** to make any changes.
3. In the **Storage Lens tier** section, review your settings. Choose **Edit** to make any changes.
4. In the **Metrics aggregation** section, review your settings. Choose **Edit** to make any changes.
5. In the **Metrics export** section, review your settings. Choose **Edit** to make any changes.
6. After reviewing and confirming all your dashboard configuration settings, choose **Submit** to update your dashboard.

After you've successfully updated your new Storage Lens dashboard, you can view your updated dashboard configuration listed under your Storage Lens **Dashboard** page.

Using the AWS CLI

Example

The following example command updates a Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-
configuration=file://./config.json --tags=file://./tags.json
```

Using the AWS SDK for Java

Example– Update a Amazon S3 Storage Lens configuration with advanced metrics and recommendations

The following examples shows you how to update the default S3 Storage Lens configuration with advanced metrics and recommendations in SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
```

```
import com.amazonaws.services.s3control.model.ActivityMetrics;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.Format;
import com.amazonaws.services.s3control.model.Include;
import com.amazonaws.services.s3control.model.OutputSchemaVersion;

            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

For access to S3 Storage Lens groups or expanded prefixes, you must upgrade your dashboard to use the advanced tier. Additional charges apply. For more information about the free and advanced tiers, see Metrics selection. For more information about S3 Storage Lens groups, see the section called “Working with Storage Lens groups”.

Disable an Amazon S3 Storage Lens dashboard

You can disable an Amazon S3 Storage Lens dashboard from the Amazon S3 console. Disabling a dashboard prevents it from generating metrics in the future. A disabled dashboard still retains its configuration information, so that it can be easily resumed when re-enabled. A disabled dashboard retains its historical data until it's no longer available for queries.

Using the S3 console

Use the following steps to disable an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

To disable an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to disable, and then choose **Disable**.
4. On the confirmation page, confirm that you want to disable the dashboard by entering the name of dashboard in the text field, and then choose **Confirm**.

Delete an Amazon S3 Storage Lens dashboard

You can't delete the default dashboard. However, you can disable it. Before deleting a dashboard that you've created, consider the following:

- As an alternative to deleting a dashboard, you can *disable* the dashboard so that it is available to be re-enabled in the future. For more information, see Using the S3 console.
- Deleting the dashboard deletes all the configuration settings that are associated with it.
- Deleting a dashboard makes all the historic metrics data unavailable. This historical data is still retained for 15 months. If you want to access this data again, create a dashboard with the same name in the same home Region as the one that was deleted.

Using the S3 console

You can delete an Amazon S3 Storage Lens dashboard from the Amazon S3 console. However, deleting a dashboard prevents it from generating metrics in the future.

Deleting an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.

3. In the **Dashboards** list, choose the dashboard that you want to delete, and then choose **Delete**.
4. On the **Delete dashboards** page, confirm that you want to delete the dashboard by entering the name of dashboard in the text field. Then choose **Confirm**.

Using the AWS CLI

Example

The following example deletes a S3 Storage Lens configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control delete-storage-lens-configuration --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Using the AWS SDK for Java

Example– Delete an Amazon S3 Storage Lens dashboard configuration

The following example shows you how to delete an S3 Storage Lens configuration using SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
```

```
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.deleteStorageLensConfiguration(new
 DeleteStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

List Amazon S3 Storage Lens dashboards

Using the S3 console

To list S3 Storage Lens dashboards

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**. You can now view the dashboards in your AWS account.

Using the AWS CLI

Example

The following example command lists the S3 Storage Lens dashboards in your AWS account. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-
east-1 --next-token=abcdefghij1234
```

Example

The following example lists S3 Storage Lens configurations without a next token. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1
```

Using the AWS SDK for Java

Example– List S3 Storage Lens dashboard configurations

The following examples shows you how to list S3 Storage Lens configurations in SDK for Java. To use this example, replace the *user input placeholders* with your own information." to each example description.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationEntry;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationsRequest;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class ListDashboard {

    public static void main(String[] args) {
        String sourceAccountId = "111122223333";
        String nextToken = "nextToken";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();
```

```
            final List<ListStorageLensConfigurationEntry> configurations =
                    s3ControlClient.listStorageLensConfigurations(new
 ListStorageLensConfigurationsRequest()
                            .withAccountId(sourceAccountId)
                            .withNextToken(nextToken)
                    ).getStorageLensConfigurationList();

            System.out.println(configurations.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

View an Amazon S3 Storage Lens dashboard configuration details

You can view a Amazon S3 Storage Lens dashboard from the Amazon S3 console, AWS CLI, and SDK for Java.

Using the S3 console

To view S3 Storage Lens dashboard configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. From the **Dashboards** list, choose the dashboard that you want to view. You can now view the details of your Storage Lens dashboard.

Using the AWS CLI

Example

The following example retrieves an S3 Storage Lens configuration so that you can view the configuration details. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control get-storage-lens-configuration --account-id=222222222222 --config-
id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

Example– Retrieve and view an S3 Storage Lens configuration

The following example shows you how to retrieve an S3 Storage Lens configuration in SDK for Java so that you can view the configuration details. To use this example, replace the *`user input placeholders`* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationResult;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();
```

```
            final StorageLensConfiguration configuration =
                    s3ControlClient.getStorageLensConfiguration(new
 GetStorageLensConfigurationRequest()
                            .withAccountId(sourceAccountId)
                            .withConfigId(configurationId)
                    ).getStorageLensConfiguration();

            System.out.println(configuration.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Managing AWS resource tags with S3 Storage Lens

Each Amazon S3 Storage Lens dashboard is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens dashboard, you can optionally add AWS resource tags to the dashboard. You can add up to 50 tags for each Storage Lens dashboard. To create a Storage Lens dashboard with tags, you must have the following S3 Storage Lens permissions:

- `s3:ListStorageLensConfigurations`
- `s3:GetStorageLensConfiguration`
- `s3:GetStorageLensConfigurationTagging`
- `s3:PutStorageLensConfiguration`
- `s3:PutStorageLensConfigurationTagging`

You can use AWS resource tags to categorize resources according to department, line of business, or project. This is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific S3 Storage Lens dashboard based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens dashboard, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes such as tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with `aws:`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens dashboard.

Topics

- Add AWS resource tags to a Storage Lens dashboard
- Retrieve AWS resource tags for a Storage Lens dashboard
- Updating Storage Lens dashboard tags
- Deleting AWS resource tags from a S3 Storage Lens dashboard

Add AWS resource tags to a Storage Lens dashboard

The following examples demonstrate how to add AWS resource tags to an S3 Storage Lens dashboard. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add AWS resource tags to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, navigate to **Storage Lens** on the left navigation panel.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard that you want to update. Then, choose **Edit**.
5. Under **General**, choose **Add tag**.
6. On the **Add tag** page, add the new key-value pair.

> **Note**
>
> Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens dashboard.
8. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
9. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds tags to a S3 Storage Lens dashboard configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=222222222222 --
region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

The following example adds tags to an Amazon S3 Storage Lens configuration in SDK for Java. To use this example, replace the *`user input placeholders`* with your own information.

Example– Add tags to an S3 Storage Lens configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
```

```
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
 com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                    new StorageLensTag().withKey("key-1").withValue("value-1"),
                    new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
 PutStorageLensConfigurationTaggingRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
```

```
        }
    }
}
```

Retrieve AWS resource tags for a Storage Lens dashboard

The following examples demonstrate how to retrieve AWS resource tags for a S3 Storage Lens dashboard. You can get resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To retrieve the AWS resource tags for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

   > **Note**
   >
   > Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command retrieves tags for a S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration-tagging --account-id=222222222222 --
region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

Example– Get tags for an S3 Storage Lens dashboard configuration

The following example shows you how to retrieve tags for an S3 Storage Lens dashboard configuration in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;
import
 com.amazonaws.services.s3control.model.GetStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
```

```
                    .withRegion(US_WEST_2)
                    .build();

            final List<StorageLensTag> s3Tags = s3ControlClient
                    .getStorageLensConfigurationTagging(new
 GetStorageLensConfigurationTaggingRequest()
                            .withAccountId(sourceAccountId)
                            .withConfigId(configurationId)
                    ).getTags();

            System.out.println(s3Tags.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Updating Storage Lens dashboard tags

The following examples demonstrate how to update Storage Lens dashboard tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

> **Note**
>
> Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds or replaces tags on an existing Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=111122223333 --
config-id=example-dashboard-configuration-id --region=us-east-1 --config-id=your-
configuration-id
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates the AWS resource tags on an existing Storage Lens dashboard. To use this example, replace the *`user input placeholders`* with your own information.

Example– Update tags on an existing Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
 com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;
```

```
import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                    new StorageLensTag().withKey("key-1").withValue("value-1"),
                    new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
 PutStorageLensConfigurationTaggingRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting AWS resource tags from a S3 Storage Lens dashboard

The following examples demonstrate how to delete AWS resource tags from an existing Storage Lens dashboard. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete AWS resource tags from an existing Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. Choose **Remove** next to the tag that you want to remove.
7. Choose **Save changes**.

Using the AWS CLI

The following AWS CLI command deletes AWS resource tags from an existing Storage Lens dashboard. To use this example command, replace the *`user input placeholders`* with your own information.

Example

```
aws s3control delete-storage-lens-configuration-tagging --account-id=222222222222 --
config-id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes an AWS resource tag from the Storage Lens dashboard using the Amazon Resource Name (ARN) that you specify in account *`111122223333`*. To use this example, replace the *`user input placeholders`* with your own information.

Example– Delete tags for an S3 Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
 com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationTaggingRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.deleteStorageLensConfigurationTagging(new
 DeleteStorageLensConfigurationTaggingRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Helper files for using Amazon S3 Storage Lens

Use the following JSON files and its key inputs for your examples.

S3 Storage Lens example configuration in JSON

Example `config.json`

The `config.json` file contains the details of a S3 Storage Lens Organizations-level *advanced metrics and recommendations* configuration. To use the following example, replace the *`user input placeholders`* with your own information.

> **Note**
>
> Additional charges apply for advanced metrics and recommendations. For more information, see advanced metrics and recommendations.

```
{
  "Id": "SampleS3StorageLensConfiguration", //Use this property to identify your S3
 Storage Lens configuration.
  "AwsOrg": { //Use this property when enabling S3 Storage Lens for AWS Organizations.
    "Arn": "arn:aws:organizations::123456789012:organization/o-abcdefgh"
  },
  "AccountLevel": {
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },

      "IsEnabled": true
    }
  }
}
```

S3 Storage Lens example configuration with Storage Lens groups in JSON

Example `config.json`

The `config.json` file contains the details that you want to apply to your Storage Lens configuration when using Storage Lens groups. To use the example, replace the *`user input placeholders`* with your own information.

To attach all Storage Lens groups to your dashboard, update your Storage Lens configuration with the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
      "IsEnabled":true
      },
    "StorageLensGroupLevel": {},
  "IsEnabled": true
}
```

To include only two Storage Lens groups in your Storage Lens dashboard configuration (*`slg-1`* and *`slg-2`*), use the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
```

```
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
      "IsEnabled":true
      },
   "StorageLensGroupLevel": {
        "SelectionCriteria": {
            "Include": [
                "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slg-1",
                "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slg-2"
            ]
    },
  "IsEnabled": true
}
```

To exclude only certain Storage Lens groups from being attached to your dashboard configuration, use the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
      "IsEnabled":true
      },
   "StorageLensGroupLevel": {
```

```
        "SelectionCriteria": {
            "Exclude": [
                "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slg-1",
                "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slg-2"
            ]
    },
  "IsEnabled": true
}
```

S3 Storage Lens example tags configuration in JSON

Example `tags.json`

The `tags.json` file contains the tags that you want to apply to your S3 Storage Lens configuration. To use this example, replace the *`user input placeholders`* with your own information.

```
[
    {
        "Key": "key1",
        "Value": "value1"
    },
    {
        "Key": "key2",
        "Value": "value2"
    }
]
```

S3 Storage Lens example configuration IAM permissions

Example `permissions.json` – Specific dashboard name

This example policy shows an S3 Storage Lens IAM `permissions.json` file with a specific dashboard name specified. Replace *`value1`*, *`us-east-1`*, *`your-dashboard-name`*, and *`example-account-id`* with your own values.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetStorageLensConfiguration",
                "s3:DeleteStorageLensConfiguration",
                "s3:PutStorageLensConfiguration"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/key1": "value1"
                }
            },
            "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens/your-
dashboard-name"
        }
    ]
}
```

Example `permissions.json` – No specific dashboard name

This example policy shows an S3 Storage Lens IAM `permissions.json` file without a specific dashboard name specified. Replace *value1*, *us-east-1*, and *example-account-id* with your own values.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetStorageLensConfiguration",
                "s3:DeleteStorageLensConfiguration",
                "s3:PutStorageLensConfiguration"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/key1": "value1"
                }
            },
```

```
            "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens/*"
        }
    ]
}
```

Viewing metrics with Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket.

By default, all dashboards are configured with free metrics, which include metrics that you can use to understand usage and activity across your S3 storage, optimize your storage costs, and implement data-protection and access-management best practices. Free metrics are aggregated down to the bucket level. With free metrics, data is available for queries for up to 14 days.

Advanced metrics and recommendations include the following additional features that you can use to gain further insight into usage and activity across your storage and best practices for optimizing your storage:

- Contextual recommendations (available only in the dashboard)
- Advanced metrics (including activity metrics aggregated by bucket)
- Prefix aggregation
- Storage Lens group aggregation
- Storage Lens group aggregation
- Amazon CloudWatch publishing

Advanced metrics data is available for queries for 15 months. There are additional charges for using S3 Storage Lens with advanced metrics. For more information, see Amazon S3 pricing. For more information about free and advanced metrics, see Metrics selection.

Topics

- Viewing Amazon S3 Storage Lens metrics using a data export
- Monitor S3 Storage Lens metrics in CloudWatch
- Amazon S3 Storage Lens metrics use cases

Viewing S3 Storage Lens metrics on the dashboards

In the Amazon S3 console, S3 Storage Lens provides an interactive default dashboard that you can use to visualize insights and trends in your data. You can also use this dashboard to flag outliers and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the account, bucket, AWS Region, prefix, or Storage Lens group level. If you've enabled S3 Storage Lens to work with AWS Organizations, you can also generate insights at the organization level (such as data for all accounts that are part of your AWS Organizations hierarchy). The dashboard always loads for the latest date that has metrics available.

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. Amazon S3 pre-configures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing.

You can disable the default dashboard, but you can't delete it. If you disable your default dashboard, it is no longer updated. You also will no longer receive any new daily metrics in S3 Storage Lens or in the **Account snapshot** section on the **Buckets** page. You can still see historic data in the default dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access this data, you can re-enable the default dashboard within the expiration period.

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts. You can also scope your dashboards by organization if you've enabled Storage Lens to work with AWS Organizations. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

You can disable or delete any additional dashboards that you create.

- If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data for free metrics until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access this data, you can re-enable the dashboard within the expiration period.
- If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

- Understanding your S3 Storage Lens dashboard

Viewing an Amazon S3 Storage Lens dashboard

The following procedure shows how to view an S3 Storage Lens dashboard in the S3 console. For use-case based walkthroughs that show how to use your dashboard to optimize costs, implement best practices, and improve the performance of applications that access your S3 buckets, see Amazon S3 Storage Lens metrics use cases.

> **Note**
>
> You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required AWS Identity and Access Management (IAM) permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see Setting Amazon S3 Storage Lens permissions and Security best practices in IAM in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

Your dashboard opens in S3 Storage Lens. The **Snapshot for *date*** section shows the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads the latest date that has metrics available.

4. (Optional) To change the date for your S3 Storage Lens dashboard, in the date selector, choose a new date.
5. (Optional) To apply temporary filters to further limit the scope of your dashboard data, do the following:

   a. Expand the **Filters** section.

   b. To filter by specific accounts, AWS Regions, storage classes, buckets, prefixes, or Storage Lens groups, choose the options to filter by.

   > **Note**
   >
   > The **Prefixes** filter and the **Storage Lens groups** filter can't be applied at the same time.

   c. To update a filter, choose **Apply**.

   d. To remove a filter, choose the **X** next to the filter.
6. In any section in your S3 Storage Lens dashboard, to see data for a specific metric, for **Metric**, choose the metric name.
7. In any chart or visualization in your S3 Storage Lens dashboard, you can drill down into deeper levels of aggregation by using the **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes**, or **Storage Lens groups** tabs. For an example, see Uncover cold Amazon S3 buckets.

Understanding your S3 Storage Lens dashboard

Your S3 Storage Lens dashboard has a primary **Overview** tab, and up to five additional tabs that represent each aggregation level:

- **Accounts**
- **AWS Regions**
- **Storage classes**
- **Buckets**
- **Prefixes**

- **Storage Lens groups**

On the **Overview** tab, your dashboard data is aggregated into three different sections: **Snapshot for *date***, **Trends and distributions**, and **Top N overview**.

For more information about your S3 Storage Lens dashboard, see the following sections.

Snapshot

The **Snapshot for *date*** section shows summary metrics that S3 Storage Lens has aggregated for the date selected. These summary metrics include the following metrics:

- **Total storage** – The total amount of storage used in bytes.
- **Object count** – The total number of objects in your AWS account.
- **Average object size** – The average object size.
- **Active buckets** – The total number of active buckets in active usage with storage > 0 bytes in your account.
- **Accounts** – The number of accounts whose storage is in scope. This value is **1** unless you are using AWS Organizations and your S3 Storage Lens has trusted access with a valid service-linked role. For more information, see Using service-linked roles for Amazon S3 Storage Lens.
- **Buckets** – The total number of buckets in your account.

Metric data

For each metric that appears in the snapshot, you can see the following data:

- **Metric name** – The name of the metric.
- **Metric category** – The category that the metric is organized into.
- **Total for *date*** – The total count for the date selected.
- **% change** – The percentage change from the last snapshot date.
- **30-day trend** – A trend-line showing the changes for the metric over a 30-day period.
- **Recommendation** – A contextual recommendation based on the data that's provided in the snapshot. Recommendations are available with advanced metrics and recommendations. For more information, see Recommendations.

Metrics categories

You can optionally update your dashboard **Snapshot for *date*** section to display metrics for other categories. If you want to see snapshot data for additional metrics, you can choose from the following **Metrics categories**:

- **Cost optimization**
- **Data protection**
- **Activity** (available with advanced metrics)
- **Access management**
- **Performance**
- **Events**

The **Snapshot for *date*** section displays only a selection of metrics for each category. To see all metrics for a specific category, choose the metric in the **Trends and distributions** or **Top N overview** sections. For more information about metric categories, see Metrics categories. For a complete list of S3 Storage Lens metrics, see Amazon S3 Storage Lens metrics glossary.

Trends and distributions

The second section of the **Overview** tab is **Trends and distributions**. In the **Trends and distributions** section, you can choose two metrics to compare over a date range that you define. The **Trends and distributions** section shows the relationship between two metrics over time. This section displays charts that you can use to see the **Storage class** and **Region** distribution between the two trends that you are tracking. You can optionally drill down into a data point in one of the charts for deeper analysis.

For a walkthrough that uses the **Trends and distributions** section, see Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS).

Top N overview

The third section of the S3 Storage Lens dashboard is **Top N overview** (sorted in ascending or descending order). This section displays your selected metrics across the top number of accounts, AWS Regions, buckets, prefixes, or Storage Lens groups. If you enabled S3 Storage Lens to work with AWS Organizations, you can also see your selected metrics across your organization.

For a walkthrough that uses the **Top N overview** section, see Identify your largest S3 buckets.

Drill down and analyze by options

To provide a fluid experience for analysis, the S3 Storage Lens dashboard provides an action menu, which appears when you choose any chart value. To use this menu, choose any chart value to see the associated metrics values, and then choose from two options in the box that appears:

- The **Drill down** action applies the selected value as a filter across all tabs of your dashboard. You can then drill down into that value for deeper analysis.
- The **Analyze by** action takes you to the **Dimension** tab that you select and applies that tab value as a filter. These tabs include **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes** (for dashboards that have **Advanced metrics** and **Prefix aggregation** enabled), and **Storage Lens groups** (for dashboards that have **Advanced metrics** and **Storage Lens group aggregation** enabled). With **Analyze by**, you can view the data in the context of the new dimension for deeper analysis.

The **Drill down** and **Analyze by** actions might be disabled if the outcome would yield illogical results or would not have any value. Both the **Drill down** and **Analyze by** actions apply filters on top of any existing filters across all tabs of the dashboard. You can also remove the filters as needed.

Tabs

The dimension-level tabs provide a detailed view of all values within a particular dimension. For example, the **AWS Regions** tab shows metrics for all AWS Regions, and the **Buckets** tab shows metrics for all buckets. Each dimension tab contains an identical layout consisting of four sections:

- A trend chart that displays your top *N* items within the dimension over the last 30 days for the selected metric. By default, this chart displays the top 10 items, but you can decrease it to at least 3 items or increase it up to 50 items.
- A histogram chart that shows a vertical bar chart for the selected date and metric. If you have a large number of items to display in this chart, you might need to scroll horizontally.
- A bubble analysis chart that plots all items within the dimension. This chart represents the first metric on the x axis and the second metric on the y axis. The third metric is represented by the size of the bubble.
- A metric grid view that contains each item in the dimension listed in rows. The columns represent each available metric, arranged in metrics category tabs for easier navigation.

Viewing Amazon S3 Storage Lens metrics using a data export

Amazon S3 Storage Lens metrics are generated daily in CSV or Apache Parquet-formatted metrics export files and placed in an S3 general purpose bucket in your account. From there, you can ingest the metrics export into the analytics tools of your choice, such as AWS Quick and Amazon Athena, where you can analyze storage usage and activity trends. You can also send daily metric exports to an AWS-managed S3 table bucket for immediate querying, using AWS analytics services or third-party tools.

Topics

- Using an AWS KMS key to encrypt your metrics exports
- What is an S3 Storage Lens export manifest?
- Understanding the Amazon S3 Storage Lens export schemas

Using an AWS KMS key to encrypt your metrics exports

To grant Amazon S3 Storage Lens permission to encrypt your metrics exports by using a customer managed key, you must use a key policy. To update your key policy so that you can use a KMS key to encrypt your S3 Storage Lens metrics exports, follow these steps.

To grant S3 Storage Lens permissions to encrypt data by using your KMS key

1. Sign into the AWS Management Console by using the AWS account that owns the customer managed key.
2. Open the AWS KMS console at https://console.aws.amazon.com/kms.
3. To change the AWS Region, use the **Region selector**.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the key that you want to use to encrypt the metrics exports. AWS KMS keys are Region-specific and must be in the same Region as the metrics export destination S3 bucket.
6. Under **Key policy**, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. Under **Edit key policy**, add the following key policy to the existing key policy. To use this policy, replace the *user input placeholders* with your information.

```
{
```

```
    "Sid": "Allow Amazon S3 Storage Lens use of the KMS key",
     "Effect": "Allow",
    "Principal": {
        "Service": "storage-lens.s3.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
       "StringEquals": {
           "aws:SourceArn": "arn:aws:s3:us-east-1:       source-account-
id:storage-lens/your-dashboard-name",
           "aws:SourceAccount": "source-account-id"
        }
     }
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following topics in the *AWS Key Management Service Developer Guide*:

- Create a KMS key
- Key policies in AWS KMS

You can also use the AWS KMS PUT key policy API operation (PutKeyPolicy) to copy the key policy to the customer managed keys that you want to use to encrypt the metrics exports by using the REST API, AWS CLI, and SDKs.

What is an S3 Storage Lens export manifest?

S3 Storage Lens daily metrics exports in general-purpose buckets may be split into multiple files due to the large amount of data aggregated. The manifest file `manifest.json` describes where the metrics export files for that day are located. Whenever a new export is delivered, it's accompanied by a new manifest. Each manifest contained in the `manifest.json` file provides metadata and other basic information about the export.

The manifest information includes the following properties:

- `sourceAccountId` – The account ID of the configuration owner.
- `configId` – A unique identifier for the dashboard.
- `destinationBucket` – The destination bucket Amazon Resource Name (ARN) that the metrics export is placed in.
- `reportVersion` – The version of the export.
- `reportDate` – The date of the report.
- `reportFormat` – The format of the report.
- `reportSchema` – The schema of the report.
- `reportFiles` – The actual list of the export report files that are in the destination bucket.

Manifest destination path example:

```
user-defined-prefix/StorageLens/111122223333/example-dashboard-configuration-id/V_1/
manifests/dt=2025-03-18/manifest.json
```

The following example shows a `manifest.json` file for a CSV-formatted Storage Lens default metrics report:

```
{
   "sourceAccountId": "111122223333",
   "configId": "example-dashboard-configuration-id",
   "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",
   "reportVersion": "V_1",
   "reportDate": "2025-07-15",
   "reportFormat": "CSV",
   "reportSchema":
 "version_number,configuration_id,report_date,aws_account_number,aws_region,storage_class,recor

   "reportFiles": [
        {
            "key": "DestinationPrefix/StorageLens/111122223333/example-dashboard-
configuration-id/V_1/reports/dt=2025-07-15/12345678-1234-1234-1234-123456789012.csv",
            "size": 1603959,
            "md5Checksum": "2177e775870def72b8d84febe1ad3574"
        }
   ]
}
```

The following example shows a `manifest.json` file for a CSV-formatted Storage Lens expanded prefixes metrics report:

```
{
   "sourceAccountId": "111122223333",
   "configId": "example-dashboard-configuration-id",
   "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",
   "reportVersion": "V_1",
   "reportDate": "2025-11-03",
   "reportFormat": "CSV",
   "reportSchema":
 "version_number,configuration_id,report_date,aws_account_number,aws_region,storage_class,recor

   "reportFiles": [
        {
            "key": "DestinationPrefix/StorageLensExpandedPrefixes/111122223333/example-
dashboard-configuration-id/V_1/reports/dt=2025-11-03/EXAMPLE1234-56ab-78cd-90ef-
EXAMPLE11111.csv",
            "size": 1603959,
            "md5Checksum": "2177e775870def72b8d84febe1ad3574"
        }
      ]
}
```

The following example shows a `manifest.json` file for a Parquet-formatted Storage Lens default metrics report:

```
{
   "sourceAccountId": "111122223333",
   "configId": "example-dashboard-configuration-id",
   "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",
   "reportVersion": "V_1",
   "reportDate": "2025-11-03",
   "reportFormat": "Parquet",
   "reportSchema": "message s3.storage.lens { required string version_number;
 required string configuration_id; required string report_date; required string
 aws_account_number; required string aws_region; required string storage_class;
 required string record_type; required string record_value; required string
 bucket_name; required string metric_name; required long metric_value; }",
   "reportFiles": [
      {
         "key": "DestinationPrefix/StorageLens/111122223333/example-dashboard-
configuration-id/V_1/reports/dt=2025-11-03/bd23de7c-b46a-4cf4-bcc5-b21aac5be0f5.par",
```

```
         "size": 14714,
         "md5Checksum": "b5c741ee0251cd99b90b3e8eff50b944"
      }
   ]
}
```

The following example shows a `manifest.json` file for a Parquet-formatted Storage Lens expanded prefixes metrics report:

```
{
   "sourceAccountId": "111122223333",
   "configId": "example-dashboard-configuration-id",
   "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",
   "reportVersion": "V_1",
   "reportDate": "2025-11-03",
   "reportFormat": "Parquet",
   "reportSchema": "message s3.storage.lens { required string version_number;
 required string configuration_id; required string report_date; required string
 aws_account_number; required string aws_region; required string storage_class;
 required string record_type; required string record_value; required string
 bucket_name; required string metric_name; required long metric_value; }",
   "reportFiles": [
      {
         "key": "DestinationPrefix/StorageLensExpandedPrefixes/111122223333/example-
dashboard-configuration-id/V_1/reports/dt=2025-11-03/bd23de7c-b46a-4cf4-bcc5-
b21aac5be0f5.par",
         "size": 14714,
         "md5Checksum": "b5c741ee0251cd99b90b3e8eff50b944"
      }
   ]
}
```

You can configure your metrics export to be generated as part of your dashboard configuration in the Amazon S3 console or by using the Amazon S3 REST API, AWS CLI, and SDKs.

Understanding the Amazon S3 Storage Lens export schemas

S3 Storage Lens export schemas vary depending on your export destination. Choose the appropriate schema based on whether you're exporting to S3 general purpose buckets or S3 tables.

Topics

- Export schema for S3 general purpose buckets

- Export schemas for S3 tables

Export schema for S3 general purpose buckets

The following table contains the schema of your S3 Storage Lens metrics export when exporting to S3 general purpose buckets.

Attribute name	Data type	Column name	Description
VersionNumber	String	version_number	The version of the export report.
ConfigurationId	String	configuration_id	The configuration_id of your S3 Storage Lens configuration.
ReportDate	String	report_date	The date that the metrics were tracked.
AwsAccountNumber	String	aws_account_number	Your AWS account number.
AwsRegion	String	aws_region	The AWS Region for which the metrics are being tracked.
StorageClass	String	storage_class	The storage class of the bucket in question.
RecordType	ENUM	record_type	The type of artifact that is being reported (ACCOUNT, BUCKET, or PREFIX).
RecordValue	String	record_value	The value of the RecordType artifact.

Attribute name	Data type	Column name	Description
			Note The `record_value` is URL-encoded.
`BucketName`	String	`bucket_name`	The name of the bucket that is being reported.
`MetricName`	String	`metric_name`	The name of the metric that is being reported.
`MetricValue`	Long	`metric_value`	The value of the metric that is being reported.

Example of an S3 Storage Lens metrics export

The following is an example of an S3 Storage Lens metrics export based on this schema.

Note

You can identify metrics for Storage Lens groups by looking for the `STORAGE_LENS_GROUP_BUCKET` or `STORAGE_LENS_GROUP_ACCOUNT` values in the `record_type` column. The `record_value` column will display the Amazon Resource Name (ARN) for the Storage Lens group, for example, `arn:aws:s3:us-east-1:123456789012:storage-lens-group/slg-1`.

version_r	configuration_id	report_date	aws_account_number	aws_region	storage_class	record_type	record_value	bucket_name	metric_name	metric_value

Export schemas for S3 tables

When exporting S3 Storage Lens metrics to S3 tables, the data is organized into three separate table schemas: storage metrics, bucket property metrics, and activity metrics.

Topics

- Storage metrics table schema
- Bucket property metrics table schema
- Activity metrics table schema

Storage metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamptz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to
aws_region	string	Region
storage_class	string	Storage Class
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX, LENS_GROUP.
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix
bucket_name	string	Bucket name
object_count	long	Number of objects stored for the current referenced item
storage_bytes	DECIMAL(38,0)	Number of bytes stored for the current referenced item
bucket_key_sse_kms_object_count	long	Number of objects encrypted with a customer managed key stored for the current referenced item
bucket_key_sse_kms_storage_bytes	DECIMAL(38,0)	Number of bytes encrypted with a customer managed key stored for the current referenced item

Name	Type	Description
current_version_object_count	long	Number of current version objects stored for the current referenced item
current_version_storage_bytes	DECIMAL(38,0)	Number of current version bytes stored for the current referenced item
delete_marker_object_count	long	Number of delete marker objects stored for the current referenced item
delete_marker_storage_bytes	DECIMAL(38,0)	Number of delete marker bytes stored for the current referenced item
encrypted_object_count	long	Number of encrypted objects stored for the current referenced item
encrypted_storage_bytes	DECIMAL(38,0)	Number of encrypted bytes stored for the current referenced item
incomplete_mpu_object_older_than_7_days_count	long	Number of incomplete multipart upload objects older than 7 days stored for the current referenced item
incomplete_mpu_storage_older_than_7_days_bytes	DECIMAL(38,0)	Number of incomplete multipart upload bytes stored older than 7 days for the current referenced item

Name	Type	Description
incomplete_mpu_object_count	long	Number of incomplete multipart upload objects stored for the current referenced item
incomplete_mpu_storage_bytes	DECIMAL(38,0)	Number of incomplete multipart upload bytes stored for the current referenced item
non_current_version_object_count	long	Number of non-current version objects stored for the current referenced item
non_current_version_storage_bytes	DECIMAL(38,0)	Number of non-current version bytes stored for the current referenced item
object_lock_enabled_object_count	long	Number of objects stored for for objects with lock enabled in the current referenced item
object_lock_enabled_storage_bytes	DECIMAL(38,0)	Number of bytes stored for objects with lock enabled in the current referenced item
replicated_object_count	long	Number of objects replicated for the current referenced item
replicated_storage_bytes	DECIMAL(38,0)	Number of bytes replicated for the current referenced item
replicated_object_source_count	long	Number of objects replicated as source stored for the current referenced item

Name	Type	Description
replicated_storage_source_bytes	DECIMAL(38,0)	Number of bytes replicated as source for the current referenced item
sse_kms_object_count	long	Number of objects encrypted with SSE key stored for the current referenced item
sse_kms_storage_bytes	DECIMAL(38,0)	Number of bytes encrypted with SSE key stored for the current referenced item
object_0kb_count	long	Number of objects with size equal to 0KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_0kb_to_128kb_count	long	Number of objects with size greater than 0KB and less than or equal to 128KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_128kb_to_256kb_count	long	Number of objects with size greater than 128KB and less than or equal to 256KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_256kb_to_512kb_count	long	Number of objects with size greater than 256KB and less than or equal to 512KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_512kb_to_1mb_count	long	Number of objects with size greater than 512KB and less than or equal to 1MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Name	Type	Description
object_1mb_to_2mb_count	long	Number of objects with size greater than 1MB and less than or equal to 2MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_2mb_to_4mb_count	long	Number of objects with size greater than 2MB and less than or equal to 4MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_4mb_to_8mb_count	long	Number of objects with size greater than 4MB and less than or equal to 8MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_8mb_to_16mb_count	long	Number of objects with size greater than 8MB and less than or equal to 16MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_16mb_to_32mb_count	long	Number of objects with size greater than 16MB and less than or equal to 32MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_32mb_to_64mb_count	long	Number of objects with size greater than 32MB and less than or equal to 64MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_64mb_to_128mb_count	long	Number of objects with size greater than 64MB and less than or equal to 128MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Name	Type	Description
object_128mb_to_256mb_count	long	Number of objects with size greater than 128MB and less than or equal to 256MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_256mb_to_512mb_count	long	Number of objects with size greater than 256MB and less than or equal to 512MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_512mb_to_1gb_count	long	Number of objects with size greater than 512MB and less than or equal to 1GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_1gb_to_2gb_count	long	Number of objects with size greater than 1GB and less than or equal to 2GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_2gb_to_4gb_count	long	Number of objects with size greater than 2GB and less than or equal to 4GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_larger_than_4gb_count	long	Number of objects with size greater than 4GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Bucket property metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table

Name	Type	Description
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamptz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX, LENS GROUP.
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix.
aws_region	string	Region
storage_class	string	Storage Class
bucket_name	string	Bucket name
versioning_enabled_bucket_count	long	Number of buckets with versioning enabled for the current referenced item
mfa_delete_enabled_bucket_count	long	Number of buckets with MFA delete enabled for the current referenced item
sse_kms_enabled_bucket_count	long	Number of buckets with KMS enabled for the current referenced item

Name	Type	Description
object_ownership_bucket_owner_enforced_bucket_count	long	Number of buckets with Object Ownership bucket owner enforced for the current referenced item
object_ownership_bucket_owner_preferred_bucket_count	long	Number of buckets with Object Ownership bucket owner preferred for the current referenced item
object_ownership_object_writer_bucket_count	long	Number of buckets with Object Ownership object writer for the current referenced item
transfer_acceleration_enabled_bucket_count	long	Number of buckets with transfer acceleration enabled for the current referenced item
event_notification_enabled_bucket_count	long	Number of buckets with event notification enabled for the current referenced item
transition_lifecycle_rule_count	long	Number of transition lifecycle rules for the current referenced item

Name	Type	Description
expiration_lifecycle_rule_count	long	Number of expiration lifecycle rules for the current referenced item
non_current_version_transition_lifecycle_rule_count	long	Number of noncurrent version transition lifecycle rules for the current referenced item
non_current_version_expiration_lifecycle_rule_count	long	Number of noncurrent version expiration lifecycle rules for the current referenced item
abort_incomplete_multipart_upload_lifecycle_rule_count	long	Number of abort incomplete multipart upload lifecycle rules for the current referenced item
expired_object_delete_marker_lifecycle_rule_count	long	Number of expire object delete marker lifecycle rules for the current referenced item
same_region_replication_rule_count	long	Number of Same-Region Replication rule count for the current referenced item

Name	Type	Description
cross_region_replication_rule_count	long	Number of Cross-Region Replication rule count for the current referenced item
same_account_replication_rule_count	long	Number of Same-account replication rule count for the current referenced item
cross_account_replication_rule_count	long	Number of Cross-account replication rule count for the current referenced item
invalid_destination_replication_rule_count	long	Number of buckets with Invalid destination replication for the current referenced item

Activity metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamp tz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to

Name	Type	Description
aws_region	string	Region
storage_class	string	Storage Class
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX.
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix
bucket_name	string	Bucket name
all_request_count	long	Number of _all_ requests for the current referenced item
all_sse_kms_encrypted_request_count	long	Number of KMS encrypted requests for the current referenced item
all_unsupported_sig_request_count	long	Number of unsupported sig requests for the current referenced item
all_unsupported_tls_request_count	long	Number of unsupported TLS requests for the current referenced item
bad_request_error_400_count	long	Number of 400 bad request errors for the current referenced item
delete_request_count	long	Number of delete requests for the current referenced item

Name	Type	Description
downloaded_bytes	decimal(0,0)	Number of downloaded bytes for the current referenced item
error_4xx_count	long	Number of 4xx errors for the current referenced item
error_5xx_count	long	Number of 5xx errors for the current referenced item
forbidden_error_403_count	long	Number of 403 forbidden errors for the current referenced item
get_request_count	long	Number of get requests for the current referenced item
head_request_count	long	Number of head requests for the current referenced item
internal_server_error_500_count	long	Number of 500 internal server errors for the current referenced item
list_request_count	long	Number of list requests for the current referenced item
not_found_error_404_count	long	Number of 404 not found errors for the current referenced item
ok_status_200_count	long	Number of 200 OK requests for the current referenced item
partial_content_status_206_count	long	Number of 206 partial content requests for the current referenced item
post_request_count	long	Number of post requests for the current referenced item

Name	Type	Description
put_request_count	long	Number of put requests for the current referenced item
select_request_count	long	Number of select requests for the current referenced item
select_returned_bytes	decimal(0,0)	Number of bytes returned by select requests for the current referenced item
select_scanned_bytes	decimal(0,0)	Number of bytes scanned by select requests for the current referenced item
service_unavailable_error_503_count	long	Number of 503 service unavailable errors for the current referenced item
uploaded_bytes	decimal(0,0)	Number of uploaded bytes for the current referenced item
average_first_byte_latency	long	Average per-request time between when an S3 bucket receives a complete request and when it starts returning the response, measured over the past 24 hours
average_total_request_latency	long	Average elapsed per-request time between the first byte received and the last byte sent to an S3 bucket, measured over the past 24 hours
read_0kb_request_count	long	Number of GetObject requests with data sizes of 0KB, including both range-based requests and whole object requests
read_0kb_to_128kb_request_count	long	Number of GetObject requests with data sizes greater than 0KB and up to 128KB, including both range-based requests and whole object requests

Name	Type	Description
read_128kb_to_256kb_request_count	long	Number of GetObject requests with data sizes greater than 128KB and up to 256KB, including both range-based requests and whole object requests
read_256kb_to_512kb_request_count	long	Number of GetObject requests with data sizes greater than 256KB and up to 512KB, including both range-based requests and whole object requests
read_512kb_to_1mb_request_count	long	Number of GetObject requests with data sizes greater than 512KB and up to 1MB, including both range-based requests and whole object requests
read_1mb_to_2mb_request_count	long	Number of GetObject requests with data sizes greater than 1MB and up to 2MB, including both range-based requests and whole object requests
read_2mb_to_4mb_request_count	long	Number of GetObject requests with data sizes greater than 2MB and up to 4MB, including both range-based requests and whole object requests
read_4mb_to_8mb_request_count	long	Number of GetObject requests with data sizes greater than 4MB and up to 8MB, including both range-based requests and whole object requests
read_8mb_to_16mb_request_count	long	Number of GetObject requests with data sizes greater than 8MB and up to 16MB, including both range-based requests and whole object requests
read_16mb_to_32mb_request_count	long	Number of GetObject requests with data sizes greater than 16MB and up to 32MB, including both range-based requests and whole object requests

Name	Type	Description
read_32mb_to_64mb_request_count	long	Number of GetObject requests with data sizes greater than 32MB and up to 64MB, including both range-based requests and whole object requests
read_64mb_to_128mb_request_count	long	Number of GetObject requests with data sizes greater than 64MB and up to 128MB, including both range-based requests and whole object requests
read_128mb_to_256mb_request_count	long	Number of GetObject requests with data sizes greater than 128MB and up to 256MB, including both range-based requests and whole object requests
read_256mb_to_512mb_request_count	long	Number of GetObject requests with data sizes greater than 256MB and up to 512MB, including both range-based requests and whole object requests
read_512mb_to_1gb_request_count	long	Number of GetObject requests with data sizes greater than 512MB and up to 1GB, including both range-based requests and whole object requests
read_1gb_to_2gb_request_count	long	Number of GetObject requests with data sizes greater than 1GB and up to 2GB, including both range-based requests and whole object requests
read_2gb_to_4gb_request_count	long	Number of GetObject requests with data sizes greater than 2GB and up to 4GB, including both range-based requests and whole object requests
read_larger_than_4gb_request_count	long	Number of GetObject requests with data sizes greater than 4GB, including both range-based requests and whole object requests

Name	Type	Description
write_0kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes of 0KB
write_0kb_to_128kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 0KB and up to 128KB
write_128kb_to_256kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 128KB and up to 256KB
write_256kb_to_512kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 256KB and up to 512KB
write_512kb_to_1mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 512KB and up to 1MB
write_1mb_to_2mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 1MB and up to 2MB
write_2mb_to_4mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 2MB and up to 4MB
write_4mb_to_8mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 4MB and up to 8MB
write_8mb_to_16mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 8MB and up to 16MB

Name	Type	Description
write_16mb_to_32mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 16MB and up to 32MB
write_32mb_to_64mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 32MB and up to 64MB
write_64mb_to_128mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 64MB and up to 128MB
write_128mb_to_256mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 128MB and up to 256MB
write_256mb_to_512mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 256MB and up to 512MB
write_512mb_to_1gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 512MB and up to 1GB
write_1gb_to_2gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 1GB and up to 2GB
write_2gb_to_4gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 2GB and up to 4GB

Name	Type	Description
write_larger_than_4gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 4GB
concurrent_put_503_error_count	long	Number of 503 errors that are generated due to concurrent writes to the same object
cross_region_request_count	long	Number of requests that originate from a client in different Region than bucket's home Region
cross_region_transferred_bytes	decimal(0,0)	Number of bytes that are transferred from calls in different Region than bucket's home Region
cross_region_without_replication_request_count	long	Number of requests that originate from a client in different Region than bucket's home Region, excluding cross-region replication requests
cross_region_without_replication_transferred_bytes	decimal(0,0)	Number of bytes that are transferred from calls in different Region than bucket's home Region, excluding cross-region replication bytes
inregion_request_count	long	Number of requests that originate from a client in same Region as bucket's home Region
inregion_transferred_bytes	decimal(0,0)	Number of bytes that are transferred from calls from same Region as bucket's home Region

Name	Type	Description
`unique_objects_accessed_daily_count`	long	Number of objects that were accessed at least once in last 24 hrs

Monitor S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the Amazon CloudWatch User Guide.

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, and AWS SDKs. Dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations can use the CloudWatch publishing option. For S3 Storage Lens advanced metrics and recommendations pricing, see Amazon S3 pricing. No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see Amazon CloudWatch pricing.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

> **Note**
>
> S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for

S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

After you enable the CloudWatch publishing option, you can use the following CloudWatch features to monitor and analyze your S3 Storage LensStorage Lens data:

- Dashboards – Use CloudWatch dashboards to create customized S3 Storage Lens dashboards. Share your CloudWatch dashboard with people who don't have direct access to your AWS account, across teams, with stakeholders, and with people external to your organizations.
- Alarms and triggered actions – Configure alarms that watch metrics and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.
- Anomaly detection – Enable anomaly detection to continuously analyze metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on the expected value of a metric. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.
- Metric math – You can also use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric to get the average object size by dividing `StorageBytes` by `ObjectCount`.

For more information about the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

- Working with S3 Storage Lens metrics in CloudWatch

S3 Storage Lens metrics and dimensions

To send S3 Storage Lens metrics to CloudWatch, you must enable the CloudWatch publishing option within S3 Storage Lens advanced metrics. After advanced metrics are enabled, you can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. You can use dimensions to filter your S3

Storage Lens metrics in CloudWatch by organization, account, bucket, storage class, Region, and metrics configuration ID.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

> **Note**
>
> S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

For more information about S3 Storage Lens metrics and dimensions in CloudWatch, see the following topics.

Topics

- Metrics
- Dimensions

Metrics

S3 Storage Lens metrics are available as metrics within CloudWatch. S3 Storage Lens metrics are published to the `AWS/S3/Storage-Lens` namespace. This namespace is only for S3 Storage Lens metrics. Amazon S3 bucket, request, and replication metrics are published to the `AWS/S3` namespace.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for

bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

In S3 Storage Lens, metrics are aggregated and stored only in the designated home Region. S3 Storage Lens metrics are also published to CloudWatch in the home Region that you specify in the S3 Storage Lens configuration.

For a complete list of S3 Storage Lens metrics, including a list of those metrics available in CloudWatch, see Amazon S3 Storage Lens metrics glossary.

> **Note**
>
> The valid statistic for S3 Storage Lens metrics in CloudWatch is Average. For more information about statistics in CloudWatch, see CloudWatch statistics definitions in the *Amazon CloudWatch User Guide*.

Granularity of S3 Storage Lens metrics in CloudWatch

S3 Storage Lens offers metrics at organization, account, bucket, and prefix granularity. S3 Storage Lens publishes organization, account, and bucket-level S3 Storage Lens metrics to CloudWatch. Prefix-level S3 Storage Lens metrics are not available in CloudWatch.

For more information about the granularity of S3 Storage Lens metrics available in CloudWatch, see the following list:

- **Organization** – Metrics aggregated across the member accounts in your organization. S3 Storage Lens publishes metrics for member accounts to CloudWatch in the management account.
  - **Organization and account** – Metrics for the member accounts in your organization.
  - **Organization and bucket** – Metrics for Amazon S3 buckets in the member accounts of your organization.
- **Account** (Non-organization level) – Metrics aggregated across the buckets in your account.
- **Bucket** (Non-organization level) – Metrics for a specific bucket. In CloudWatch, S3 Storage Lens publishes these metrics to the AWS account that created the S3 Storage Lens configuration. S3 Storage Lens publishes these metrics only for non-organization configurations.

Dimensions

When S3 Storage Lens sends data to CloudWatch, dimensions are attached to each metric. Dimensions are categories that describe the characteristics of metrics. You can use dimensions to filter the results that CloudWatch returns.

For example, all S3 Storage Lens metrics in CloudWatch have the `configuration_id` dimension. You can use this dimension to differentiate between metrics associated with a specific S3 Storage Lens configuration. The `organization_id` identifies organization-level metrics. For more information about dimensions in CloudWatch, see Dimensions in the *CloudWatch User Guide*.

Different dimensions are available for S3 Storage Lens metrics depending on the granularity of the metrics. For example, you can use the `organization_id` dimension to filter organization-level metrics by the AWS Organizations ID. However, you can't use this dimension for bucket and account-level metrics. For more information, see Filtering metrics using dimensions.

To see which dimensions are available for your S3 Storage Lens configuration, see the following table.

Dimension	Description	Bucket	Account	Organization	Organization and account	Organization and bucket
`configuration_id`	The dashboard name for the S3 Storage Lens configuration reported in the metrics	✓	✓	✓	✓	✓
`metrics_version`	The version of the S3 Storage Lens metrics. The metrics version has a fixed value of `1.0`.	✓	✓	✓	✓	✓
`organization_id`	The AWS Organizations ID for the metrics	✗	✗	✓	✓	✓
`aws_account_number`	The AWS account that's associated with the metrics	✓	✓	✗	✓	✓
`aws_region`	The AWS Region for the metrics	✓	✓	✓	✓	✓

Dimension	Description	Bucket	Account	Organization	Organization and account	Organization and bucket
bucket_name	The name of the S3 bucket that's reported in the metrics	✓	✗	✗	✓	✗
storage_class	The storage class for the bucket that's reported in the metrics	✓	✓	✓	✓	✓
record_type	The granularity of the metrics: ORGANIZATION, ACCOUNT, BUCKET	✓ BUCKET	✓ ACCOUNT	✓ ORGANIZATION	✓ ACCOUNT	✓ BUCKET

Enabling CloudWatch publishing for S3 Storage Lens

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the Amazon CloudWatch User Guide.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

You can enable CloudWatch support for new or existing dashboard configurations by using the S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see Amazon S3 pricing. No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply.

To enable the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

> **Note**
>
> S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.
> Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

Using the S3 console

When you update an S3 Storage Lens dashboard, you can't change the dashboard name or home Region. You also can't change the scope of the default dashboard, which is scoped to your entire account's storage.

To update an S3 Storage Lens dashboard to enable CloudWatch publishing

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **S3 Storage Lens**, **Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit.**
4. Under **Metrics selection**, choose **Advanced metrics and recommendations**.

   Advanced metrics and recommendations are available for an additional charge. Advanced metrics and recommendations include a 15-month period for data queries, usage metrics aggregated at the prefix level, activity metrics aggregated by bucket, the CloudWatch publishing option, and contextual recommendations that help you optimize storage costs and apply data-protection best practices. For more information, see Amazon S3 pricing.
5. Under **Select Advanced metrics and recommendations features**, select **CloudWatch publishing**.

> **Important**
>
> If your configuration enables prefix aggregation for usage metrics, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

6. Choose **Save changes**.

To create a new S3 Storage Lens dashboard that enables CloudWatch support

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. Choose **Create dashboard**.
4. Under **General**, define the following configuration options:

   a. For **Dashboard name**, enter your dashboard name.

   Dashboard names must be fewer than 65 characters and must not contain special characters or spaces. You can't change the dashboard name after you create your dashboard.

   b. Choose the **Home Region** for your dashboard.

   Metrics for all Regions included in this dashboard scope are stored centrally in the designated home Region. In CloudWatch, S3 Storage Lens metrics are also available in the home Region. You can't change the home Region after you create your dashboard.

5. (Optional) To add tags, choose **Add tag** and enter the tag **Key** and **Value**.

> **Note**
>
> You can add up to 50 tags to your dashboard configuration.

6. Define the scope for your configuration:

   a. If you're creating an organization-level configuration, choose the accounts to include in the configuration: **Include all accounts in your configuration** or **Limit the scope to your signed-in account**.

> **Note**
>
> When you create an organization-level configuration that includes all accounts, you can include or exclude only Regions, not buckets.

b. Choose the Regions and buckets that you want S3 Storage Lens to include in the dashboard configuration by doing the following:

- To include all Regions, choose **Include Regions and buckets**.
- To include specific Regions, clear **Include all Regions**. Under **Choose Regions to include**, choose the Regions that you want S3 Storage Lens to include in the dashboard.
- To include specific buckets, clear **Include all buckets**. Under **Choose buckets to include**, choose the buckets that you want S3 Storage Lens to include in the dashboard.

> **Note**
>
> You can choose up to 50 buckets.

7. For **Metrics selection**, choose **Advanced metrics and recommendations**.

   For more information about advanced metrics and recommendations pricing, see Amazon S3 pricing.

8. Under **Advanced metrics and recommendations features**, select the options that you want to enable:

- **Advanced metrics**
- **CloudWatch publishing**

> **Important**
>
> If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

- **Prefix aggregation**

> **Note**
>
> For more information about advanced metrics and recommendations features, see Metrics selection.

9. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

   - **Activity metrics**
   - **Detailed status code metrics**
   - **Advanced cost optimization metrics**
   - **Advanced data protection metrics**

   For more information about metrics categories, see Metrics categories. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

10. (Optional) Configure your metrics export.

    For more information about how to configure a metrics export, see step Using the S3 console.

11. Choose **Create dashboard**.

Using the AWS CLI

The following AWS CLI example enables the CloudWatch publishing option by using a S3 Storage Lens organization-level advanced metrics and recommendations configuration. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=555555555555 --config-
id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./
config.json

config.json

        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Using the REST API

To enable the CloudWatch publishing option by using the Amazon S3 REST API, you can use PutStorageLensConfiguration.

Next steps

After you enable the CloudWatch publishing option, you can access your S3 Storage Lens metrics in CloudWatch. You also can leverage CloudWatch features to monitor and analyze your S3 Storage Lens data in CloudWatch. For more information, see the following topics:

- S3 Storage Lens metrics and dimensions
- Working with S3 Storage Lens metrics in CloudWatch

Working with S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications,

including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the Amazon CloudWatch User Guide.

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see Amazon S3 pricing. No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see Amazon CloudWatch pricing.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics, you can access account-level and bucket-level metrics by configuration ID, account, bucket (for bucket-level metrics only), Region, and storage class in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.
Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

For more information about working with S3 Storage Lens metrics in CloudWatch, see the following topics.

Topics

- Working with CloudWatch dashboards
- Setting alarms, triggering actions, and using anomaly detection
- Filtering metrics using dimensions
- Calculating new metrics with metric math

- Using search expressions in graphs

Working with CloudWatch dashboards

You can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view.

CloudWatch has broad permissions control that doesn't support limiting access to a specific set of metrics or dimensions. Users in your account or organization who have access to CloudWatch will have access to metrics for all S3 Storage Lens configurations where the CloudWatch support option is enabled. You can't manage permissions for specific dashboards as you can in S3 Storage Lens. For more information about CloudWatch permissions, see Managing access permissions to your CloudWatch resources in the *Amazon CloudWatch User Guide*.

For more information about using CloudWatch dashboards and configuring permissions, see Using Amazon CloudWatch dashboards and Sharing CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

Setting alarms, triggering actions, and using anomaly detection

You can configure CloudWatch alarms that watch S3 Storage Lens metrics in CloudWatch and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.

You can also enable anomaly detection to continuously analyze your S3 Storage Lens metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on a metric's expected value. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

For more information and examples, see Using Amazon CloudWatch alarms and Creating an alarm from a metric on a graph in the *Amazon CloudWatch User Guide*.

Filtering metrics using dimensions

You can use dimensions to filter S3 Storage Lens metrics in the CloudWatch console. For example, you can filter by `configuration_id`, `aws_account_number`, `aws_region`, `bucket_name`, and more.

S3 Storage Lens supports multiple dashboard configurations per account. This means that different configurations can include the same bucket. When these metrics are published to CloudWatch, the bucket will have duplicate metrics within CloudWatch. To view metrics only for a specific S3 Storage Lens configuration in CloudWatch, you can use the `configuration_id` dimension. When you filter by `configuration_id`, you see only the metrics that are associated with the configuration that you identify.

For more information about filtering by configuration ID, see Searching for available metrics in the *Amazon CloudWatch User Guide*.

Calculating new metrics with metric math

You can use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric for unencrypted objects by subtracting Encrypted Objects from Object Count. You can also create a metric to get the average object size by dividing `StorageBytes` by `ObjectCount` or the number bytes accessed on one day by dividing `BytesDownloaded` by `StorageBytes`.

For more information, see Using metric math in the *Amazon CloudWatch User Guide*.

Using search expressions in graphs

With S3 Storage Lens metrics, you can create a search expression. For example, you can create a search expression for all metrics that are named **IncompleteMultipartUploadStorageBytes** and add SUM to the expression. With this search expression, you can see your total incomplete multipart upload bytes across all dimensions of your storage in a single metric.

This example shows the syntax that you would use to create a search expression for all metrics named **IncompleteMultipartUploadStorageBytes**.

```
SUM(SEARCH('{AWS/S3/Storage-
Lens,aws_account_number,aws_region,configuration_id,metrics_version,record_type,storage_class}
 MetricName="IncompleteMultipartUploadStorageBytes"', 'Average',86400))
```

For more information about this syntax, see CloudWatch search expression syntax in the *Amazon CloudWatch User Guide*. To create a CloudWatch graph with a search expression, see Creating a CloudWatch graph with a search expressionin the *Amazon CloudWatch User Guide*.

Amazon S3 Storage Lens metrics use cases

You can use your Amazon S3 Storage Lens dashboard to visualize insights and trends, flag outliers, and receive recommendations. S3 Storage Lens metrics are organized into categories that align with key use cases. You can use these metrics to do the following:

- Identify cost-optimization opportunities
- Apply data-protection best practices
- Apply access-management best practices
- Improve the performance of application workloads

For example, with cost-optimization metrics, you can identify opportunities to reduce your Amazon S3 storage costs. You can identify buckets with multipart uploads that are more than 7-days old or buckets that are accumulating noncurrent versions.

Similarly, you can use data-protection metrics to identify buckets that aren't following data-protection best practices within your organization. For example, you can identify buckets that don’t use AWS Key Management Service keys (SSE-KMS) for default encryption or don't have S3 Versioning enabled.

With S3 Storage Lens access-management metrics, you can identify bucket settings for S3 Object Ownership so that you can migrate access control list (ACL) permissions to bucket policies and disable ACLs.

If you have S3 Storage Lens advanced metrics enabled, you can use detailed status-code metrics to get counts for successful or failed requests that you can use to troubleshoot access or performance issues.

With advanced metrics, you can also access additional cost-optimization and data-protection metrics that you can use to identify opportunities to further reduce your overall S3 storage costs and better align with best practices for protecting your data. For example, advanced cost-optimization metrics include lifecycle rule counts that you can use to identify buckets that don't have lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. Advanced data-protection metrics include replication rule counts.

For more information about metrics categories, see Metrics categories. For a complete list of S3 Storage Lens metrics, see Amazon S3 Storage Lens metrics glossary.

Topics

- Using Amazon S3 Storage Lens to optimize your storage costs
- Using S3 Storage Lens to protect your data
- Using S3 Storage Lens to audit Object Ownership settings
- Using S3 Storage Lens metrics to improve performance

Using Amazon S3 Storage Lens to optimize your storage costs

You can use S3 Storage Lens cost-optimization metrics to reduce the overall cost of your S3 storage. Cost-optimization metrics can help you confirm that you've configured Amazon S3 cost effectively and according to best practices. For example, you can identify the following cost-optimization opportunities:

- Buckets with incomplete multipart uploads older than 7 days
- Buckets that are accumulating numerous noncurrent versions
- Buckets that don't have lifecycle rules to abort incomplete multipart uploads
- Buckets that don't have lifecycle rules to expire noncurrent versions objects
- Buckets that don't have lifecycle rules to transition objects to a different storage class

You can then use this data to add additional lifecycle rules to your buckets.

The following examples show how you can use cost- optimization metrics in your S3 Storage Lens dashboard to optimize your storage costs.

Topics

- Identify your largest S3 buckets
- Uncover cold Amazon S3 buckets
- Locate incomplete multipart uploads
- Reduce the number of noncurrent versions retained
- Identify buckets that don't have lifecycle rules and review lifecycle rule counts

Identify your largest S3 buckets

You pay for storing objects in S3 buckets. The rate that you're charged depends on your objects' sizes, how long you store the objects, and their storage classes. With S3 Storage Lens, you get a centralized view of all the buckets in your account. To see all the buckets in all of your

organization's accounts, you can configure an AWS Organizations-level S3 Storage Lens dashboard. From this dashboard view, you can identify your largest buckets.

Step 1: Identify your largest buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

   When the dashboard opens, you can see the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads to the latest date that has metrics available.
4. To see a ranking of your largest buckets by the **Total storage** metric for a selected date range, scroll down to the **Top N overview for *date*** section.

   You can toggle the sort order to show the smallest buckets. You can also adjust the **Metric** selection to rank your buckets by any of the available metrics. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.
5. For more detailed insights about your buckets, scroll up to the top of the page, and then choose the **Bucket** tab.

   On the **Bucket** tab, you can see details such as the recent growth rate, the average object size, the largest prefixes, and the number of objects.

Step 2: Navigate to your buckets and investigate

After you've identified your largest S3 buckets, you can navigate to each bucket within the S3 console to view the objects in the bucket, understand its associated workload, and identify its internal owners. You can contact the bucket owners to find out whether the growth is expected or whether the growth needs further monitoring and control.

Uncover cold Amazon S3 buckets

If you have S3 Storage Lens advanced metrics enabled, you can use activity metrics to understand how cold your S3 buckets are. A "cold" bucket is one whose storage is no longer accessed (or very rarely accessed). This lack of activity typically indicates that the bucket's objects aren't frequently accessed.

Activity metrics, such as **GET Requests** and **Download Bytes**, indicate how often your buckets are accessed each day. To understand the consistency of the access pattern and to spot buckets that are no longer being accessed at all, you can trend this data over several months. The **Retrieval rate** metric, which is computed as **Download bytes / Total storage**, indicates the proportion of storage in a bucket that is accessed daily.

> **Note**
>
> Download bytes are duplicated in cases where the same object is downloaded multiple times during the day.

Prerequisite

To see activity metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Activity metrics**. For more information, see Using the S3 console.

Step 1: Identify active buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. Choose the **Bucket** tab, and then scroll down to the **Bubble analysis by buckets for *date*** section.

   In the **Bubble analysis by buckets for *date*** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.
5. To find buckets that have gone cold, for **X-axis**, **Y-axis**, and **Size**, choose the **Total storage**, **% retrieval rate**, and **Average object size** metrics.

6. In the **Bubble analysis by buckets for *date*** section, locate any buckets with retrieval rates of zero (or near zero) and a larger relative storage size, and choose the bubble that represents the bucket.

   A box will appear with choices for more granular insights. Do one of the following:

   a. To update the **Bucket** tab to display metrics only for the selected bucket, choose **Drill down**, and then choose **Apply**.
   b. To aggregate your bucket-level data to by account, AWS Region, storage class, or bucket, choose **Analyze by** and then make a choice for **Dimension**. For example, to aggregate by storage class, choose **Storage class** for **Dimension**.

   To find buckets that have gone cold, do a bubble analysis using the **Total storage**, **% retrieval rate**, and **Average object size** metrics. Look for any buckets with retrieval rates of zero (or near zero) and a larger relative storage size.

   The **Bucket** tab of your dashboard updates to display data for your selected aggregation or filter. If you aggregated by storage class or another dimension, that new tab opens in your dashboard (for example, the **Storage class** tab).

Step 2: Investigate cold buckets

From here, you can identify the owners of cold buckets in your account or organization and find out if that storage is still needed. You can then optimize costs by configuring lifecycle expiration configurations for these buckets or archiving the data in one of the Amazon Glacier storage classes.

To avoid the problem of cold buckets going forward, you can automatically transition your data by using S3 Lifecycle configurations for your buckets, or you can enable auto-archiving with S3 Intelligent-Tiering.

You can also use step 1 to identify hot buckets. Then, you can ensure that these buckets use the correct S3 storage class to ensure that they serve their requests most effectively in terms of performance and cost.

Locate incomplete multipart uploads

You can use multipart uploads to upload very large objects (up to 50 TB) as a set of parts for improved throughput and quicker recovery from network issues. In cases where the multipart upload process doesn't finish, the incomplete parts remain in the bucket (in an unusable state).

These incomplete parts incur storage costs until the upload process is finished, or until the incomplete parts are removed. For more information, see Uploading and copying objects using multipart upload in Amazon S3.

With S3 Storage Lens, you can identify the number of incomplete multipart upload bytes in your account or across your entire organization, including incomplete multipart uploads that are more than 7 days old. For a complete list of incomplete multipart upload metrics, see Amazon S3 Storage Lens metrics glossary.

As a best practice, we recommend configuring lifecycle rules to expire incomplete multipart uploads that are older than a specific number of days. When you create your lifecycle rule to expire incomplete multipart uploads, we recommend 7 days as a good starting point.

Step 1: Review overall trends for incomplete multipart uploads

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for *date*** section, under **Metrics categories**, choose **Cost optimization**.

   The **Snapshot for *date*** section updates to display **Cost optimization** metrics, which include **Incomplete multipart upload bytes greater than 7 days old**.

   In any chart in your S3 Storage Lens dashboard, you can see metrics for incomplete multipart uploads. You can use these metrics to further assess the impact of incomplete multipart upload bytes on your storage, including their contribution to overall growth trends. You can also drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Bucket**, or **Storage class** tabs for a deeper analysis of your data. For an example, see Uncover cold Amazon S3 buckets.

Step 2: Identify buckets that have the most incomplete multipart upload bytes but don't have lifecycle rules to abort incomplete multipart uploads

Prerequisite

To see the **Abort incomplete multipart upload lifecycle rule count** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see Using the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets that are accumulating incomplete multipart uploads greater than 7 days old, go to the **Top N overview for *date*** section.

   By default, the **Top N overview for *date*** section displays metrics for the top 3 buckets. You can increase or decrease the number of buckets in the **Top N** field. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. (This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.)

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

5. For **Metric**, choose **Incomplete multipart upload bytes greater than 7 days old** in the **Cost optimization** category.

   Under **Top *number* buckets**, you can see the buckets with the most incomplete multipart upload storage bytes that are greater than 7 days old.
6. To view more detailed bucket-level metrics for incomplete multipart uploads, choose the **Bucket** tab.
7. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.
8. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ().
9. Clear the toggles for all cost-optimization metrics until only **Incomplete multipart upload bytes greater than 7 days old** and **Abort incomplete multipart upload lifecycle rule count** remain selected.

10. (Optional) Under **Page size**, choose the number of buckets to display in the list.
11. Choose **Confirm**.

    The **Buckets** list updates to display bucket-level metrics for incomplete multipart uploads and lifecycle rule counts. You can use this data to identify buckets that have the most incomplete multipart upload bytes that are greater than 7 days old and are missing lifecycle rules to abort incomplete multipart uploads. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to delete abandoned incomplete multipart uploads.

Step 3: Add a lifecycle rule to delete incomplete multipart uploads after 7 days

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle configuration to expire incomplete multipart upload bytes from a bucket after a specified number of days. For more information, see Configuring a bucket lifecycle configuration to delete incomplete multipart uploads.

Reduce the number of noncurrent versions retained

When enabled, S3 Versioning retains multiple distinct copies of the same object that you can use to quickly recover data if an object is accidentally deleted or overwritten. If you've enabled S3 Versioning without configuring lifecycle rules to transition or expire noncurrent versions, a large number of previous noncurrent versions can accumulate, which can have storage-cost implications. For more information, see Retaining multiple versions of objects with S3 Versioning.

Step 1: Identify buckets with the most noncurrent object versions

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for *date*** section, under **Metric categories**, choose **Cost optimization**.

   The **Snapshot for *date*** section updates to display **Cost optimization** metrics, which include the metric for **% noncurrent version bytes**. The **% noncurrent version bytes** metric represents the proportion of your total storage bytes that is attributed to noncurrent versions, within the dashboard scope and for the selected date.

> **Note**
>
> If your **% noncurrent version bytes** is greater than 10 percent of your storage at the account level, you might be storing too many object versions.

5. To identify specific buckets that are accumulating a large number of noncurrent versions:

   a. Scroll down to the **Top N overview for *date*** section. For **Top N**, enter the number of buckets that you would like to see data for.

   b. For **Metric**, choose **% noncurrent version bytes**.

      Under **Top *number* buckets**, you can see the buckets (for the number that you specified) with the highest **% noncurrent version bytes**. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

      > **Note**
      >
      > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

   c. To view more detailed bucket-level metrics for noncurrent object versions, choose the **Bucket** tab.

      In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see Uncover cold Amazon S3 buckets.

   d. In the **Buckets** section, for **Metric categories**, select **Cost optimization**. Then, clear **Summary**.

      You can now see the **% noncurrent version bytes** metric, along with other metrics related to noncurrent versions.

Step 2: Identify buckets that are missing transition and expiration lifecycle rules for managing noncurrent versions

Prerequisite

To see the **Noncurrent version transition lifecycle rule count** and **Noncurrent version expiration lifecycle rule count** metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see Using the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.
6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon
   ().
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
   - **% noncurrent version bytes**
   - **Noncurrent version transition lifecycle rule count**
   - **Noncurrent version expiration lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list updates to display metrics for noncurrent version bytes and noncurrent version lifecycle rule counts. You can use this data to identify buckets that have a high percentage of noncurrent version bytes but are missing transition and expiration lifecycle rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules to transition or expire noncurrent object versions

After you've determined which buckets require further investigation, you can navigate to the buckets within the S3 console and add a lifecycle rule to expire noncurrent versions after a specified number of days. Alternatively, to reduce costs while still retaining noncurrent versions, you can configure a lifecycle rule to transition noncurrent versions to one of the Amazon Glacier storage classes. For more information, see Specifying a lifecycle rule for a versioning-enabled bucket.

Identify buckets that don't have lifecycle rules and review lifecycle rule counts

S3 Storage Lens provides S3 Lifecycle rule count metrics that you can use to identify buckets that are missing lifecycle rules. To find buckets that don't have lifecycle rules, you can use the **Total buckets without lifecycle rules** metric. A bucket with no S3 Lifecycle configuration might have storage that you no longer need or can migrate to a lower-cost storage class. You can also use lifecycle rule count metrics to identify buckets that are missing specific types of lifecycle rules, such as expiration or transition rules.

Prerequisite

To see lifecycle rule count metrics and the **Total buckets without lifecycle rules** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see Using the S3 console.

Step 1: Identify buckets without lifecycle rules

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets without lifecycle rules, scroll down to the **Top N overview for *date*** section.

   By default, the **Top N overview for *date*** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

> **Note**
>
> With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

5. For **Metric**, choose **Total buckets without lifecycle rules** from the **Cost optimization** category.
6. Review the following data for **Total buckets without lifecycle rules**:

   - **Top *number* accounts** - See which accounts that have the most buckets without lifecycle rules.
   - **Top *number* Regions** - View a breakdown of buckets without lifecycle rules by Region.
   - **Top *number* buckets** - See which buckets don't have lifecycle rules.

   In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see Uncover cold Amazon S3 buckets.

   After you identify which buckets don't have lifecycle rules, you can also review specific lifecycle rule counts for your buckets.

Step 2: Review lifecycle rule counts for your buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your S3 Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.
6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ().

7. Clear the toggles for all cost-optimization metrics until only the following remain selected:

   - **Transition lifecycle rule count**
   - **Expiration lifecycle rule count**
   - **Noncurrent version transition lifecycle rule count**
   - **Noncurrent version expiration lifecycle rule count**
   - **Abort incomplete multipart upload lifecycle rule count**
   - **Total lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list updates to display lifecycle rule count metrics for your buckets. You can use this data to identify buckets without lifecycle rules or buckets that are missing specific kinds of lifecycle rules, for example, expiration or transition rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules

After you've identified buckets with no lifecycle rules, you can add lifecycle rules. For more information, see Setting an S3 Lifecycle configuration on a bucket and Examples of S3 Lifecycle configurations.

Using S3 Storage Lens to protect your data

You can use Amazon S3 Storage Lens data-protection metrics to identify buckets where data-protection best practices haven't been applied. You can use these metrics to take action and apply standard settings that align with best practices for protecting your data across the buckets in your account or organization. For example, you can use data-protection metrics to identify buckets that don't use AWS Key Management Service (AWS KMS) keys (SSE-KMS) for default encryption or requests that use AWS Signature Version 2 (SigV2).

The following use cases provide strategies for using your S3 Storage Lens dashboard to identify outliers and apply data-protection best practices across your S3 buckets.

Topics

- Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)

- Identify buckets that have S3 Versioning enabled
- Identify requests that use AWS Signature Version 2 (SigV2)
- Count the total number of replication rules for each bucket
- Identify percentage of Object Lock bytes

Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)

With Amazon S3 default encryption, you can set the default encryption behavior for an S3 bucket. For more information, see the section called “Setting default bucket encryption”.

You can use the **SSE-KMS enabled bucket count** and **% SSE-KMS enabled buckets** metrics to identify buckets that use server-side encryption with AWS KMS keys (SSE-KMS) for default encryption. S3 Storage Lens also provides metrics for unencrypted bytes, unencrypted objects, encrypted bytes, and encrypted objects. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

You can analyze SSE-KMS encryption metrics in the context of general encryption metrics to identify buckets that don't use SSE-KMS. If you want to use SSE-KMS for all the buckets in your account or organization, you can then update the default encryption settings for these buckets to use SSE-KMS. In addition to SSE-KMS, you can use server-side encryption with Amazon S3 managed keys (SSE-S3) or customer-provided keys (SSE-C). For more information, see Protecting data with encryption.

Step 1: Identify which buckets are using SSE-KMS for default encryption

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **% SSE-KMS enabled bucket count** for the primary metric and **% encrypted bytes** for the secondary metric.

   The **Trend for *date*** chart updates to display trends for SSE-KMS and encrypted bytes.
5. To view more granular, bucket-level insights for SSE-KMS:

   a. Choose a point on the chart. A box will appear with choices for more granular insights.

b. Choose the **Buckets** dimension. Then choose **Apply**.

6. In the **Distribution by buckets for *date*** chart, choose the **SSE-KMS enabled bucket count** metric.
7. You can now see which buckets have SSE-KMS enabled and which do not.

Step 2: Update bucket default encryption settings

Now that you've determined which buckets use SSE-KMS in the context of your **% encrypted bytes**, you can identify buckets that don't use SSE-KMS. You can then optionally navigate to these buckets within the S3 console and update their default encryption settings to use SSE-KMS or SSE-S3. For more information, see Configuring default encryption.

Identify buckets that have S3 Versioning enabled

When enabled, the S3 Versioning feature retains multiple versions of the same object that can be used to quickly recover data if an object is accidentally deleted or overwritten. You can use the **Versioning-enabled bucket count** metric to see which buckets use S3 Versioning. Then, you can take action in the S3 console to enable S3 Versioning for other buckets.

Step 1: Identify buckets that have S3 Versioning enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **Versioning-enabled bucket count** for the primary metric and **Buckets** for the secondary metric.

   The **Trend for *date*** chart updates to display trends for S3 Versioning enabled buckets. Right below the trends line, you can see the **Storage class distribution** and **Region distribution** subsections.
5. To view more granular insights for any of the buckets that you see in the **Trend for *date*** chart so that you can perform a deeper analysis, do the following:

   a. Choose a point on the chart. A box will appear with choices for more granular insights.

   b. Choose a dimension to apply to your data for deeper analysis: **Account**, **AWS Region**, **Storage class**, or **Bucket**. Then choose **Apply**.

6. In the **Bubble analysis by buckets for *date*** section, choose the **Versioning-enabled bucket count**, **Buckets**, and **Active buckets** metrics.

   The **Bubble analysis by buckets for *date*** section updates to display data for the metrics that you selected. You can use this data to see which buckets have S3 Versioning enabled in the context of your total bucket count. In the **Bubble analysis by buckets for *date*** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

Step 2: Enable S3 Versioning

After you've identified buckets that have S3 Versioning enabled, you can identify buckets that have never had S3 Versioning enabled or are versioning suspended. Then, you can optionally enable versioning for these buckets in the S3 console. For more information, see Enabling versioning on buckets.

Identify requests that use AWS Signature Version 2 (SigV2)

You can use the **All unsupported signature requests** metric to identify requests that use AWS Signature Version 2 (SigV2). This data can help you identify specific applications that are using SigV2. You can then migrate these applications to AWS Signature Version 4 (SigV4).

SigV4 is the recommended signing method for all new S3 applications. SigV4 provides improved security and is supported in all AWS Regions. For more information, see Amazon S3 update - SigV2 deprecation period extended & modified.

Prerequisite

To see **All unsupported signature requests** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see Using the S3 console.

Step 1: Examine SigV2 signing trends by AWS account, Region, and bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To identify specific buckets, accounts, and Regions with requests that use SigV2:

a. Under **Top N overview for *date***, in **Top N**, enter the number of buckets that you would like to see data for.

b. For **Metric**, choose **All unsupported signature requests** from the **Data protection** category.

The **Top N overview for *date*** updates to display data for SigV2 requests by account, AWS Region, and bucket. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

> **Note**
>
> With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

Step 2: Identify buckets that are accessed by applications through SigV2 requests

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Data protection** metrics for the buckets shown.
6. To filter the **Buckets** list to display only specific data-protection metrics, choose the preferences icon ().
7. Clear the toggles for all data-protection metrics until only the following metrics remain selected:

   - **All unsupported signature requests**

- **% all unsupported signature requests**

8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list updates to display bucket-level metrics for SigV2 requests. You can use this data to identify specific buckets that have SigV2 requests. Then, you can use this information to migrate your applications to SigV4. For more information, see Authenticating Requests (AWS Signature Version 4) in the *Amazon Simple Storage Service API Reference*.

Count the total number of replication rules for each bucket

S3 Replication enables automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. For more information, see Replicating objects within and across Regions.

You can use S3 Storage Lens replication rule count metrics to get detailed per-bucket information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions.

Prerequisite

To see replication rule count metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see Using the S3 console.

Step 1: Count the total number of replication rules for each bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
6. To filter the **Buckets** list to display only replication rule count metrics, choose the preferences icon
   ().

7. Clear the toggles for all data-protection metrics until only the replication rule count metrics remain selected:

   - **Same-Region Replication rule count**
   - **Cross-Region Replication rule count**
   - **Same-account replication rule count**
   - **Cross-account replication rule count**
   - **Total replication rule count**

8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

Step 2: Add replication rules

After you have a per-bucket replication rule count, you can optionally create additional replication rules. For more information, see Examples for configuring live replication.

Identify percentage of Object Lock bytes

With S3 Object Lock, you can store objects by using a *write-once-read-many (WORM)* model. You can use Object Lock to help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can enable Object Lock only when you create a bucket and also enable S3 Versioning. However, you can edit the retention period for individual object versions or apply legal holds for buckets that have Object Lock enabled. For more information, see Locking objects with Object Lock.

You can use Object Lock metrics in S3 Storage Lens to see the **% Object Lock bytes** metric for your account or organization. You can use this information to identify buckets in your account or organization that aren't following your data-protection best practices.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot** section, under **Metrics categories**, choose **Data protection**.

The **Snapshot** section updates to display data-protection metrics, including the **% Object Lock bytes** metric. You can see the overall percentage of Object Lock bytes for your account or organization.

5. To see the **% Object Lock bytes** per bucket, scroll down to the **Top N overview** section.

   To get object-level data for Object Lock, you can also use the **Object Lock object count** and **% Object Lock objects** metrics.

6. For **Metric**, choose **% Object Lock bytes** from the **Data protection** category.

   By default, the **Top N overview for *date*** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

7. Review the following data for **% Object Lock bytes**:

   - **Top *number* accounts** - See which accounts have the highest and lowest **% Object Lock bytes**.
   - **Top *number* Regions** - View a breakdown of **% Object Lock bytes** by Region.
   - **Top *number* buckets** - See which buckets have the highest and lowest **% Object Lock bytes**.

Using S3 Storage Lens to audit Object Ownership settings

Amazon S3 Object Ownership is an S3 bucket-level setting that you can use to disable access control lists (ACLs) and control ownership of the objects in your bucket. If you set Object Ownership to bucket owner enforced, you can disable access control lists (ACLs) and take ownership of every object in your bucket. This approach simplifies access management for data stored in Amazon S3.

By default, when another AWS account uploads an object to your S3 bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through ACLs. You can use Object Ownership to change this default behavior.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. Therefore, we recommend that you disable ACLs, except in circumstances where you must control access for each object individually. By setting Object Ownership to bucket owner enforced, you can disable ACLs and rely on policies for access control. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

With S3 Storage Lens access-management metrics, you can identify buckets that don't have disabled ACLs. After identifying these buckets, you can migrate ACL permissions to policies and disable ACLs for these buckets.

Topics

- Step 1: Identify general trends for Object Ownership settings
- Step 2: Identify bucket-level trends for Object Ownership settings
- Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

Step 1: Identify general trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot for *date*** section, under **Metrics categories**, choose **Access management**.

   The **Snapshot for *date*** section updates to display the **% Object Ownership bucket owner enforced** metric. You can see the overall percentage of buckets in your account or organization that use the bucket owner enforced setting for Object Ownership to disable ACLs.

Step 2: Identify bucket-level trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.

3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To view more detailed bucket-level metrics, choose the **Bucket** tab.
5. In the **Distribution by buckets for *date*** section, choose the **% Object Ownership bucket owner enforced** metric.

   The chart updates to show a per-bucket breakdown for **% Object Ownership bucket owner enforced**. You can see which buckets use the bucket owner enforced setting for Object Ownership to disable ACLs.
6. To view the bucket owner enforced settings in context, scroll down to the **Buckets** section. For **Metrics categories**, select **Access management**. Then clear **Summary**.

   The **Buckets** list displays data for all three Object Ownership settings: bucket owner enforced, bucket owner preferred, and object writer.
7. To filter the **Buckets** list to display metrics only for a specific Object Ownership setting, choose the preferences icon
   ( ).
8. Clear the metrics that you don't want to see.
9. (Optional) Under **Page size**, choose the number of buckets to display in the list.
10. Choose **Confirm**.

Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

After you've identified buckets that use the object writer and bucket owner preferred setting for Object Ownership, you can migrate your ACL permissions to bucket policies. When you've finished migrating your ACL permissions, you can then update your Object Ownership settings to bucket owner enforced in order to disable ACLs. For more information, see Prerequisites for disabling ACLs.

Using S3 Storage Lens metrics to improve performance

If you have S3 Storage Lens advanced metrics enabled, you can use detailed status-code metrics to get counts for successful or failed requests. You can use this information to troubleshoot access or performance issues. Detailed status-code metrics show counts for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable. You can examine overall trends for detailed status-code metrics across S3 buckets, accounts, and organizations. Then, you can drill down into bucket-level metrics to identify workloads that are currently accessing these buckets and causing errors.

For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied. After you've identified these workloads, you can do a deep dive outside of S3 Storage Lens to troubleshoot your 403 Forbidden errors.

This example shows you how to do a trend analysis for the 403 Forbidden error by using the **403 Forbidden error count** and the **% 403 Forbidden errors** metrics. You can use these metrics to identify workloads that are accessing buckets without the correct permissions applied. You can do a similar trend analysis for any of the other **Detailed status code metrics**. For more information, see Amazon S3 Storage Lens metrics glossary.

Prerequisite

To see **Detailed status code metrics** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Detailed status code metrics**. For more information, see Using the S3 console.

Topics

- Step 1: Do a trend analysis for an individual HTTP status code
- Step 2: Analyze error counts by bucket
- Step 3: Troubleshoot errors

Step 1: Do a trend analysis for an individual HTTP status code

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, for **Primary metric**, choose **403 Forbidden error count** from the **Detailed status codes** category. For **Secondary metric**, choose **% 403 Forbidden errors**.
5. Scroll down to the **Top N overview for *date*** section. For **Metrics**, choose **403 Forbidden error count** or **% 403 Forbidden errors** from the **Detailed status codes** category.

   The **Top N overview for *date*** section updates to display the top 403 Forbidden error counts by account, AWS Region, and bucket.

Step 2: Analyze error counts by bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Detailed status code** metrics. Then clear **Summary**.

   The **Buckets** list updates to display all the available detailed status code metrics. You can use this information to see which buckets have a large proportion of certain HTTP status codes and which status codes are common across buckets.
6. To filter the **Buckets** list to display only specific detailed status-code metrics, choose the preferences icon ().
7. Clear the toggles for any detailed status-code metrics that you don't want to view in the **Buckets** list.
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list displays error count metrics for the number of buckets that you specified. You can use this information to identify specific buckets that are experiencing many errors and troubleshoot errors by bucket.

Step 3: Troubleshoot errors

After you identify buckets with a high proportion of specific HTTP status codes, you can troubleshoot these errors. For more information, see the following:

- Why am I getting a 403 Forbidden error when I try to upload files in Amazon S3?
- Why am I getting a 403 Forbidden error when I try to modify a bucket policy in Amazon S3?
- How do I troubleshoot 403 Forbidden errors from my Amazon S3 bucket where all the resources are from the same AWS account?
- How do I troubleshoot an HTTP 500 or 503 error from Amazon S3?

Viewing metrics in AWS managed S3 Tables

Amazon S3 Storage Lens can export your storage analytics and insights to S3 Tables, enabling you to query your Storage Lens metrics using SQL with AWS analytics services like Amazon Athena, Amazon EMR, Amazon SageMaker Studio (SMStudio), and other AWS analytics tools. When you configure S3 Storage Lens to export to S3 Tables, your metrics are automatically stored in read-only Apache Iceberg tables in the AWS-managed `aws-s3` table bucket.

This integration provides structured data access for querying Storage Lens metrics using standard SQL, analytics integration with AWS analytics services, historical analysis capabilities, and cost optimization with no additional charges for exporting to AWS-managed S3 Tables.

Topics

- Exporting S3 Storage Lens metrics to S3 Tables
- Table naming for S3 Storage Lens export to S3 Tables
- Understanding S3 Storage Lens table schemas
- Permissions for S3 Storage Lens tables
- Querying S3 Storage Lens data with analytics tools
- Using AI assistants with S3 Storage Lens tables

Exporting S3 Storage Lens metrics to S3 Tables

You can configure Amazon S3 Storage Lens to export your storage analytics and insights to S3 Tables. When you enable S3 Tables export, your metrics are automatically stored in read-only Apache Iceberg tables in the AWS-managed `aws-s3` table bucket, making them queryable using SQL with AWS analytics services like Amazon Athena, Amazon Redshift, and Amazon EMR.

> **Note**
>
> There is no additional charge for exporting S3 Storage Lens metrics to AWS-managed S3 Tables. Standard charges apply for table storage, table management, and requests on the tables. For more information, see Amazon S3 pricing.

Enable S3 Tables export using the console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, and then choose **Storage Lens Dashboards**.
3. In **Storage Lens Dashboards** list, choose the dashboard that you want to edit.
4. Choose **Edit**.
5. On the **Dashboard** page, navigate to **Metrics export and publishing** section.
6. To enable Table Export for **Default metrics report**, select **Table bucket** in the Bucket type.
7. To enable Table Export for **Expanded prefixes metrics report**, select **Table bucket** in the Bucket type.
8. Review dashboard config and choose **Submit**.

> **Note**
>
> After you enable S3 Tables export, it can take up to 48 hours for the first data to be available in the tables.

> **Note**
>
> There is no additional charge for exporting S3 Storage Lens metrics to AWS-managed S3 Tables. Standard charges apply for table storage, table management, requests on the tables, and monitoring. You can enable or disable export to S3 Tables by using the Amazon S3 console, Amazon S3 API, the AWS CLI, or AWS SDKs.

> **Note**
>
> By default, records in your S3 tables don't expire. To help minimize storage costs for your tables, you can enable and configure record expiration for the tables. With this option, Amazon S3 automatically removes records from a table when the records expire. For more information, see Record expiration for tables.

Enable S3 Tables export using the AWS CLI

> **Note**
>
> Before running the following commands, make sure that you have an up to date CLI version. See Installing or updating to the latest version of the AWS CLI.

The following example enables S3 Tables export for an S3 Storage Lens configuration "Default metrics report" using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=555555555555 --config-
id=your-configuration-id --storage-lens-configuration '{
   "Id":"your-configuration-id",
   "AccountLevel":{
      "ActivityMetrics":{
        "IsEnabled":true
      },
      "BucketLevel":{
         "ActivityMetrics":{
            "IsEnabled":true
         }
      }
   },
   "DataExport":{
      "S3BucketDestination":{
         "OutputSchemaVersion":"V_1",
         "Format":"CSV",
         "AccountId":"555555555555",
         "Arn":"arn:aws:s3:::my-export-bucket",
         "Prefix":"storage-lens-exports/"
      },
      "StorageLensTableDestination":{
         "IsEnabled":true
      }
   },
   "IsEnabled":true
}'
```

Enable S3 Tables export using the AWS SDKs

The following example enables S3 Tables export for an S3 Storage Lens configuration "Default metrics report" using the AWS SDK for Python (Boto3). To use this example, replace the *user input placeholders* with your own information.

```
import boto3

s3control = boto3.client('s3control')

response = s3control.put_storage_lens_configuration( AccountId='555555555555',
 ConfigId='your-configuration-id', StorageLensConfiguration={
        'Id': 'your-configuration-id',
        'AccountLevel': {
            'ActivityMetrics': {
              'IsEnabled': True
            },
            'BucketLevel': {
                'ActivityMetrics': {
                    'IsEnabled': True
                }
            }
        },
        'DataExport': {
            'S3BucketDestination': {
                'OutputSchemaVersion': 'V_1',
                'Format': 'CSV',
                'AccountId': '555555555555',
                'Arn': 'arn:aws:s3:::my-export-bucket',
                'Prefix': 'storage-lens-exports/'
            },
            'StorageLensTableDestination': {
                'IsEnabled': True
            }
        },
        'IsEnabled': True
    }
)
```

For more information about using the AWS SDKs, see AWS SDKs and tools.

Next steps

After enabling S3 Tables export, you can:

- Learn about Table naming for S3 Storage Lens export to S3 Tables
- Learn about Understanding S3 Storage Lens table schemas

Table naming for S3 Storage Lens export to S3 Tables

When you export S3 Storage Lens metrics to S3 Tables, the tables are organized using Apache Iceberg catalog conventions with specific naming patterns to ensure compatibility and organization.

Table location structure

The complete table location follows this pattern:

```
s3tablescatalog/aws-s3/<namespace>/<table-name>
```

Table bucket name

Table Bucket: `aws-s3`

The S3 Storage Lens export uses the `aws-s3` table bucket, which is the designated bucket for AWS S3-related system tables.

Catalog name

Catalog: `s3tablescatalog/aws-s3`

S3 Storage Lens tables are stored in the S3 catalog because Storage Lens provides insights about three types of S3 resources:

- Storage metrics
- Bucket properties
- API usage metrics

Namespace naming convention

Namespaces organize tables within the catalog. For S3 Storage Lens, the namespace is derived from your Storage Lens configuration ID.

Standard namespace format

For Storage Lens configuration IDs without dots (`.`):

```
lens_<configuration-id>_exp
```

Example: If your configuration ID is `my-lens-config`, the namespace will be:

```
lens_my-lens-config_exp
```

Namespace format with dot character or uppercase letters handling

Storage Lens configuration IDs can contain dots (`.`) or uppercase letters (`A-Z`), but S3 Tables namespaces only support lowercase letters, numbers, hyphens (`-`), and underscores (`_`). When your configuration ID contains dots, they are converted to hyphens, uppercase letters are converted to lower case letters, and a hash suffix is added for uniqueness:

```
lens_<configuration-id-with-dots-or-uppercase-replaced>_exp_<7-char-hash>
```

Example: If your configuration ID is `my.LENS.config`, the namespace will be:

```
lens_my-lens-config_exp_a1b2c3d
```

Where `a1b2c3d` is the first 7 characters of the SHA-1 hash of the original configuration ID.

Complete examples

For a Storage Lens configuration with ID `production-metrics`:

- **Table Bucket:** `aws-s3`
- **Catalog:** `s3tablescatalog/aws-s3`
- **Namespace:** `lens_production-metrics_exp`
- **Full Path:** `s3tablescatalog/aws-s3/lens_production-metrics_exp/<table-name>`

For a Storage Lens configuration with ID `prod.us.east.metrics`:

- **Table Bucket:** `aws-s3`

- **Catalog:** `s3tablescatalog/aws-s3`
- **Namespace:** `lens_prod-us-east-metrics_exp_f8e9a1b` (with hash)
- **Full Path:** `s3tablescatalog/aws-s3/lens_prod-us-east-metrics_exp_f8e9a1b/<table-name>`

Table types

The following table shows the different types of tables created for S3 Storage Lens exports:

Catalog	Namespace	S3 table name	Description
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	default_storage_metrics	This table contains the storage metrics for your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	default_activity_metrics	This table contains the activity metrics for your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	expanded_prefixes_storage_metrics	This table contains the storage metrics for all the prefixes in your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	expanded_prefixes_activity_metrics	This table contains the activity metrics for all the prefixes in your Storage Lens configuration.
s3tablescatalog/aws-s3	lens_<conf_name>_exp[_<hash>]	bucket_property_metrics	This table contains the bucket property metrics for all the buckets in your Storage Lens configuration.

Next steps

- Learn about Understanding S3 Storage Lens table schemas
- Learn about Permissions for S3 Storage Lens tables

Understanding S3 Storage Lens table schemas

When exporting S3 Storage Lens metrics to S3 tables, the data is organized into three separate table schemas: storage metrics, bucket property metrics, and activity metrics.

Storage metrics table schema

Name	Type	Description
`version_number`	string	Version identifier of the schema of the table
`configuration_id`	string	S3 Storage Lens configuration name
`report_time`	timestamptz	Date the S3 Storage Lens report refers to
`aws_account_id`	string	Account id the entry refers to
`aws_region`	string	Region
`storage_class`	string	Storage Class
`record_type`	string	Type of record, related to what is the level of aggregation of data. Values: `ACCOUNT`, `BUCKET`, `PREFIX`, `STORAGE_LENS_GROUP_BUCKET`, `STORAGE_LENS_GROUP_ACCOUNT`.
`record_value`	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix
`bucket_name`	string	Bucket name
`object_count`	long	Number of objects stored for the current referenced item
`storage_bytes`	DECIMAL(38,0)	Number of bytes stored for the current referenced item

Name	Type	Description
bucket_key_sse_kms_object_count	long	Number of objects encrypted with a customer managed key stored for the current referenced item
bucket_key_sse_kms_storage_bytes	DECIMAL(38,0)	Number of bytes encrypted with a customer managed key stored for the current referenced item
current_version_object_count	long	Number of current version objects stored for the current referenced item
current_version_storage_bytes	DECIMAL(38,0)	Number of current version bytes stored for the current referenced item
delete_marker_object_count	long	Number of delete marker objects stored for the current referenced item
delete_marker_storage_bytes	DECIMAL(38,0)	Number of delete marker bytes stored for the current referenced item
encrypted_object_count	long	Number of encrypted objects stored for the current referenced item
encrypted_storage_bytes	DECIMAL(38,0)	Number of encrypted bytes stored for the current referenced item
incomplete_mpu_object_older_than_7_days_count	long	Number of incomplete multipart upload objects older than 7 days stored for the current referenced item

Name	Type	Description
incomplete_mpu_storage_older_than_7_days_bytes	DECIMAL(38,0)	Number of incomplete multipart upload bytes stored older than 7 days for the current referenced item
incomplete_mpu_object_count	long	Number of incomplete multipart upload objects stored for the current referenced item
incomplete_mpu_storage_bytes	DECIMAL(38,0)	Number of incomplete multipart upload bytes stored for the current referenced item
non_current_version_object_count	long	Number of non-current version objects stored for the current referenced item
non_current_version_storage_bytes	DECIMAL(38,0)	Number of non-current version bytes stored for the current referenced item
object_lock_enabled_object_count	long	Number of objects stored with lock enabled for the current referenced item
object_lock_enabled_storage_bytes	DECIMAL(38,0)	Number of bytes stored for objects with lock enabled in the current referenced item
replicated_object_count	long	Number of objects replicated for the current referenced item

Name	Type	Description
replicated_storage_bytes	DECIMAL(38,0)	Number of bytes replicated for the current referenced item
replicated_object_source_count	long	Number of objects replicated as source stored for the current referenced item
replicated_storage_source_bytes	DECIMAL(38,0)	Number of bytes replicated as source for the current referenced item
sse_kms_object_count	long	Number of objects encrypted with SSE key stored for the current referenced item
sse_kms_storage_bytes	DECIMAL(38,0)	Number of bytes encrypted with SSE key stored for the current referenced item
object_0kb_count	long	Number of objects with size equal to 0KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_0kb_to_128kb_count	long	Number of objects with size greater than 0KB and less than or equal to 128KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_128kb_to_256kb_count	long	Number of objects with size greater than 128KB and less than or equal to 256KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_256kb_to_512kb_count	long	Number of objects with size greater than 256KB and less than or equal to 512KB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Name	Type	Description
object_512kb_to_1mb_count	long	Number of objects with size greater than 512KB and less than or equal to 1MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_1mb_to_2mb_count	long	Number of objects with size greater than 1MB and less than or equal to 2MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_2mb_to_4mb_count	long	Number of objects with size greater than 2MB and less than or equal to 4MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_4mb_to_8mb_count	long	Number of objects with size greater than 4MB and less than or equal to 8MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_8mb_to_16mb_count	long	Number of objects with size greater than 8MB and less than or equal to 16MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_16mb_to_32mb_count	long	Number of objects with size greater than 16MB and less than or equal to 32MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_32mb_to_64mb_count	long	Number of objects with size greater than 32MB and less than or equal to 64MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Name	Type	Description
object_64mb_to_128mb_count	long	Number of objects with size greater than 64MB and less than or equal to 128MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_128mb_to_256mb_count	long	Number of objects with size greater than 128MB and less than or equal to 256MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_256mb_to_512mb_count	long	Number of objects with size greater than 256MB and less than or equal to 512MB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_512mb_to_1gb_count	long	Number of objects with size greater than 512MB and less than or equal to 1GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_1gb_to_2gb_count	long	Number of objects with size greater than 1GB and less than or equal to 2GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_2gb_to_4gb_count	long	Number of objects with size greater than 2GB and less than or equal to 4GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers
object_larger_than_4gb_count	long	Number of objects with size greater than 4GB, including current version, noncurrent versions, incomplete multipart uploads, and delete markers

Bucket property metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamptz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX, STORAGE_LENS_GROUP_BUCKET , STORAGE_LENS_GROUP_ACCOUNT .
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix.
aws_region	string	Region
storage_class	string	Storage Class
bucket_name	string	Bucket name
versioning_enabled_bucket_count	long	Number of buckets with versioning enabled for the current referenced item
mfa_delete_enabled_bucket_count	long	Number of buckets with MFA delete enabled for the current referenced item
sse_kms_enabled_bucket_count	long	Number of buckets with KMS enabled for the current referenced item

Name	Type	Description
object_ownership_bucket_owner_enforced_bucket_count	long	Number of buckets with Object Ownership bucket owner enforced for the current referenced item
object_ownership_bucket_owner_preferred_bucket_count	long	Number of buckets with Object Ownership bucket owner preferred for the current referenced item
object_ownership_object_writer_bucket_count	long	Number of buckets with Object Ownership object writer for the current referenced item
transfer_acceleration_enabled_bucket_count	long	Number of buckets with transfer acceleration enabled for the current referenced item
event_notification_enabled_bucket_count	long	Number of buckets with event notification enabled for the current referenced item
transition_lifecycle_rule_count	long	Number of transition lifecycle rules for the current referenced item

Name	Type	Description
`expiration_lifecycle_rule_count`	long	Number of expiration lifecycle rules for the current referenced item
`non_current_version_transition_lifecycle_rule_count`	long	Number of noncurrent version transition lifecycle rules for the current referenced item
`non_current_version_expiration_lifecycle_rule_count`	long	Number of noncurrent version expiration lifecycle rules for the current referenced item
`abort_incomplete_multipart_upload_lifecycle_rule_count`	long	Number of abort incomplete multipart upload lifecycle rules for the current referenced item
`expired_object_delete_marker_lifecycle_rule_count`	long	Number of expire object delete marker lifecycle rules for the current referenced item
`same_region_replication_rule_count`	long	Number of Same-Region Replication rules for the current referenced item

Name	Type	Description
cross_region_replication_rule_count	long	Number of Cross-Region Replication rules for the current referenced item
same_account_replication_rule_count	long	Number of same-account replication rules for the current referenced item
cross_account_replication_rule_count	long	Number of cross-account replication rules for the current referenced item
invalid_destination_replication_rule_count	long	Number of buckets with invalid destination replication for the current referenced item

Activity metrics table schema

Name	Type	Description
version_number	string	Version identifier of the schema of the table
configuration_id	string	S3 Storage Lens configuration name
report_time	timestamptz	Date the S3 Storage Lens report refers to
aws_account_id	string	Account id the entry refers to

Name	Type	Description
aws_region	string	Region
storage_class	string	Storage Class
record_type	string	Type of record, related to what is the level of aggregation of data. Values: ACCOUNT, BUCKET, PREFIX, STORAGE_LENS_GROUP_BUCKET , STORAGE_LENS_GROUP_ACCOUNT .
record_value	string	Disambiguator for record types that have more than one record under them. It is used to reference the prefix
bucket_name	string	Bucket name
all_request_count	long	Number of all requests for the current referenced item
all_sse_kms_encrypted_request_count	long	Number of KMS encrypted requests for the current referenced item
all_unsupported_sig_request_count	long	Number of unsupported sig requests for the current referenced item
all_unsupported_tls_request_count	long	Number of unsupported TLS requests for the current referenced item
bad_request_error_400_count	long	Number of 400 bad request errors for the current referenced item

Name	Type	Description
delete_request_count	long	Number of delete requests for the current referenced item
downloaded_bytes	decimal(38,0)	Number of downloaded bytes for the current referenced item
error_4xx_count	long	Number of 4xx errors for the current referenced item
error_5xx_count	long	Number of 5xx errors for the current referenced item
forbidden_error_403_count	long	Number of 403 forbidden errors for the current referenced item
get_request_count	long	Number of get requests for the current referenced item
head_request_count	long	Number of head requests for the current referenced item
internal_server_error_500_count	long	Number of 500 internal server errors for the current referenced item
list_request_count	long	Number of list requests for the current referenced item
not_found_error_404_count	long	Number of 404 not found errors for the current referenced item
ok_status_200_count	long	Number of 200 OK requests for the current referenced item
partial_content_status_206_count	long	Number of 206 partial content requests for the current referenced item

Name	Type	Description
post_request_count	long	Number of post requests for the current referenced item
put_request_count	long	Number of put requests for the current referenced item
select_request_count	long	Number of select requests for the current referenced item
select_returned_bytes	decimal(38,0)	Number of bytes returned by select requests for the current referenced item
select_scanned_bytes	decimal(38,0)	Number of bytes scanned by select requests for the current referenced item
service_unavailable_error_503_count	long	Number of 503 service unavailable errors for the current referenced item
uploaded_bytes	decimal(38,0)	Number of uploaded bytes for the current referenced item
average_first_byte_latency	long	Average per-request time between when an S3 bucket receives a complete request and when it starts returning the response, measured over the past 24 hours
average_total_request_latency	long	Average elapsed per-request time between the first byte received and the last byte sent to an S3 bucket, measured over the past 24 hours
read_0kb_request_count	long	Number of GetObject requests with data sizes of 0KB, including both range-based requests and whole object requests

Name	Type	Description
read_0kb_to_128kb_request_count	long	Number of GetObject requests with data sizes greater than 0KB and up to 128KB, including both range-based requests and whole object requests
read_128kb_to_256kb_request_count	long	Number of GetObject requests with data sizes greater than 128KB and up to 256KB, including both range-based requests and whole object requests
read_256kb_to_512kb_request_count	long	Number of GetObject requests with data sizes greater than 256KB and up to 512KB, including both range-based requests and whole object requests
read_512kb_to_1mb_request_count	long	Number of GetObject requests with data sizes greater than 512KB and up to 1MB, including both range-based requests and whole object requests
read_1mb_to_2mb_request_count	long	Number of GetObject requests with data sizes greater than 1MB and up to 2MB, including both range-based requests and whole object requests
read_2mb_to_4mb_request_count	long	Number of GetObject requests with data sizes greater than 2MB and up to 4MB, including both range-based requests and whole object requests
read_4mb_to_8mb_request_count	long	Number of GetObject requests with data sizes greater than 4MB and up to 8MB, including both range-based requests and whole object requests
read_8mb_to_16mb_request_count	long	Number of GetObject requests with data sizes greater than 8MB and up to 16MB, including both range-based requests and whole object requests

Name	Type	Description
read_16mb_to_32mb_request_count	long	Number of GetObject requests with data sizes greater than 16MB and up to 32MB, including both range-based requests and whole object requests
read_32mb_to_64mb_request_count	long	Number of GetObject requests with data sizes greater than 32MB and up to 64MB, including both range-based requests and whole object requests
read_64mb_to_128mb_request_count	long	Number of GetObject requests with data sizes greater than 64MB and up to 128MB, including both range-based requests and whole object requests
read_128mb_to_256mb_request_count	long	Number of GetObject requests with data sizes greater than 128MB and up to 256MB, including both range-based requests and whole object requests
read_256mb_to_512mb_request_count	long	Number of GetObject requests with data sizes greater than 256MB and up to 512MB, including both range-based requests and whole object requests
read_512mb_to_1gb_request_count	long	Number of GetObject requests with data sizes greater than 512MB and up to 1GB, including both range-based requests and whole object requests
read_1gb_to_2gb_request_count	long	Number of GetObject requests with data sizes greater than 1GB and up to 2GB, including both range-based requests and whole object requests
read_2gb_to_4gb_request_count	long	Number of GetObject requests with data sizes greater than 2GB and up to 4GB, including both range-based requests and whole object requests

Name	Type	Description
read_larger_than_4gb_request_count	long	Number of GetObject requests with data sizes greater than 4GB, including both range-based requests and whole object requests
write_0kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes of 0KB
write_0kb_to_128kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 0KB and up to 128KB
write_128kb_to_256kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 128KB and up to 256KB
write_256kb_to_512kb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 256KB and up to 512KB
write_512kb_to_1mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 512KB and up to 1MB
write_1mb_to_2mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 1MB and up to 2MB
write_2mb_to_4mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 2MB and up to 4MB

Name	Type	Description
write_4mb_to_8mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 4MB and up to 8MB
write_8mb_to_16mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 8MB and up to 16MB
write_16mb_to_32mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 16MB and up to 32MB
write_32mb_to_64mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 32MB and up to 64MB
write_64mb_to_128mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 64MB and up to 128MB
write_128mb_to_256mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 128MB and up to 256MB
write_256mb_to_512mb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 256MB and up to 512MB
write_512mb_to_1gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 512MB and up to 1GB

Name	Type	Description
write_1gb_to_2gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 1GB and up to 2GB
write_2gb_to_4gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 2GB and up to 4GB
write_larger_than_4gb_request_count	long	Number of PutObject, UploadPart, and CreateMultipartUpload requests with data sizes greater than 4GB
concurrent_put_503_error_count	long	Number of 503 errors that are generated due to concurrent writes to the same object
cross_region_request_count	long	Number of requests that originate from a client in different Region than bucket's home Region
cross_region_transferred_bytes	decimal(38,0)	Number of bytes that are transferred from calls in different Region than bucket's home Region
cross_region_without_replication_request_count	long	Number of requests that originate from a client in different Region than bucket's home Region, excluding cross-region replication requests
cross_region_without_replication_transferred_bytes	decimal(38,0)	Number of bytes that are transferred from calls in different Region than bucket's home Region, excluding cross-region replication bytes

Name	Type	Description
`inregion_request_count`	long	Number of requests that originate from a client in same Region as bucket's home Region
`inregion_transferred_bytes`	decimal(38,0)	Number of bytes that are transferred from calls from same Region as bucket's home Region
`unique_objects_accessed_daily_count`	long	Number of objects that were accessed at least once in last 24 hrs

- Review the Amazon S3 Storage Lens metrics glossary for detailed metric definitions

Permissions for S3 Storage Lens tables

To work with S3 Storage Lens data exported to S3 Tables, you need appropriate AWS Identity and Access Management (IAM) permissions. This topic covers the permissions required for exporting metrics and managing encryption.

Permissions for metrics export to S3 Tables

To create and work with S3 Storage Lens tables and table buckets, you must have certain `s3tables` permissions. At a minimum, to configure S3 Storage Lens to S3 Tables, you must have the following `s3tables` permissions:

- `s3tables:CreateTableBucket` – This permission allows you to create an AWS-managed table bucket. All S3 Storage Lens metrics in your account are stored in a single AWS-managed table bucket named `aws-s3`.

- `s3tables:PutTableBucketPolicy` – S3 Storage Lens uses this permission to set a table bucket policy that allows `systemtables.s3.amazonaws.com` access to the bucket so that logs can be delivered.

> **Important**
>
> If you remove permissions for the service principal `systemtables.s3.amazonaws.com`, S3 Storage Lens will not be able to update the S3 tables with data based on your configuration. We recommend adding other access control policies in addition to the policy already provided, instead of editing the canned policy that is added when your table bucket is set up.

> **Note**
>
> A separate S3 table for each type of metric export is created for each Storage Lens configuration. If you have multiple Storage Lens configurations in the Region, separate tables are created for additional configurations. For example, there are three types of tables available for your S3 table bucket.

Permissions for AWS KMS encrypted tables

All data in S3 tables including S3 Storage Lens metrics are encrypted with SSE-S3 encryption by default. You can choose to encrypt your Storage Lens metrics report with AWS KMS keys (SSE-KMS). If you choose to encrypt your S3 Storage Lens metric reports with KMS keys, you must have additional permissions.

1. The user or IAM role needs the following permissions. You can grant these permissions by using the IAM console at https://console.aws.amazon.com/iam/.
   - `kms:DescribeKey` on the AWS KMS key used
2. On the key policy for the AWS KMS key, you need the following permissions. You can grant these permissions by using the AWS KMS console at https://console.aws.amazon.com/kms. To use this policy, replace the *`user input placeholders`* with your own information.

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "EnableSystemTablesKeyUsage",
            "Effect": "Allow",
            "Principal": {
                "Service": "systemtables.s3.amazonaws.com"
            },
            "Action": [
                "kms:DescribeKey",
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                }
            }
        },
        {
            "Sid": "EnableKeyUsage",
            "Effect": "Allow",
            "Principal": {
                "Service": "maintenance.s3tables.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id",
            "Condition": {
                "StringLike": {
                    "kms:EncryptionContext:aws:s3:arn": "<table-bucket-arn>/*"
                }
            }
        }
    ]
}
```

Service-linked role for S3 Storage Lens

S3 Storage Lens uses a service-linked role to write metrics to S3 Tables. This role is automatically created when you enable S3 Tables export for the first time in your account. The service-linked role has the following permissions:

- `s3tables:CreateTable` - To create tables in the `aws-s3` table bucket
- `s3tables:PutTableData` - To write metrics data to tables
- `s3tables:GetTable` - To retrieve table metadata

You don't need to manually create or manage this service-linked role. For more information about service-linked roles, see Using service-linked roles in the *IAM User Guide*.

Best practices for permissions

Follow these best practices when configuring permissions for S3 Storage Lens tables:

- **Use least privilege** - Grant only the permissions required for specific tasks. For example, if users only need to query data, don't grant permissions to modify Storage Lens configurations.
- **Use IAM roles** - Use IAM roles instead of long-term access keys for applications and services that access S3 Storage Lens tables.
- **Enable AWS CloudTrail** - Enable CloudTrail logging to monitor access to S3 Storage Lens tables and track permission changes.
- **Use resource-based policies** - When possible, use resource-based policies to control access to specific tables or namespaces.
- **Regularly review permissions** - Periodically review and audit IAM policies and Lake Formation permissions to ensure they follow the principle of least privilege.

Troubleshooting permissions

Access denied when enabling S3 Tables export

Problem: You receive an "access denied" error when trying to enable S3 Tables export.

Solution: Verify that your IAM user or role has the `s3:PutStorageLensConfiguration` permission and the necessary S3 Tables permissions.

Access denied when querying tables

Problem: You receive an "access denied" error when querying S3 Storage Lens tables in Amazon Athena.

Solution: Verify that:

- Analytics integration is enabled on the `aws-s3` table bucket
- Lake Formation permissions are correctly configured
- Your IAM user or role has the necessary Amazon Athena permissions

KMS encryption errors

Problem: You receive KMS-related errors when accessing encrypted tables.

Solution: Verify that:

- Your IAM policy includes the required KMS permissions
- The KMS key policy grants permissions to the S3 Storage Lens service principal
- The KMS key is in the same Region as your Storage Lens configuration

- Learn about Using AI assistants with S3 Storage Lens tables

Querying S3 Storage Lens data with analytics tools

Before you can query S3 Storage Lens data exported to S3 Tables using AWS analytics services like Amazon Athena or Amazon EMR, you must enable analytics integration on the AWS-managed `aws-s3` table bucket and configure AWS Lake Formation permissions.

Important

Enabling analytics integration on the "aws-s3" table bucket is a required step that is often missed. Without this configuration, you will not be able to query your S3 Storage Lens tables using AWS analytics services.

Prerequisites

Before you begin, ensure that you have:

- An S3 Storage Lens configuration with S3 Tables export enabled. For more information, see Exporting S3 Storage Lens metrics to S3 Tables .
- Access to Amazon Athena or another analytics service.
- Waited 24-48 hours after enabling export for the first data to be available.

Integration overview

For detailed information about integrating S3 Tables with AWS analytics services, including prerequisites, IAM role configuration, and step-by-step procedures, see Integrating Amazon S3 Tables with AWS analytics services.

After you enable S3 Tables export and set up analytics integration, you can query your S3 Storage Lens data using AWS analytics services such as Amazon Athena, Amazon Redshift, and Amazon EMR. This enables you to perform custom analysis, create dashboards, and derive insights from your storage data using standard SQL.

Querying with Amazon Athena

Amazon Athena is a serverless interactive query service that makes it easy to analyze data using standard SQL. Use the following steps to query S3 Storage Lens data in Athena.

Note

In all query examples, replace `lens_my-config_exp` with your actual Storage Lens configuration namespace. For more information about namespace naming, see Table naming for S3 Storage Lens export to S3 Tables .

Example: Query top storage consumers

The following query identifies the top 10 buckets by storage consumption:

```
SELECT
    bucket_name,
    storage_class,
    SUM(storage_bytes) / POWER(1024, 3) AS storage_gb,
    SUM(object_count) AS objects
FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics"
WHERE report_time = (
    SELECT MAX(report_time)
    FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics"
)
    AND record_type = 'BUCKET'
    AND bucket_name != ''
GROUP BY bucket_name, storage_class
ORDER BY storage_gb DESC
LIMIT 10
```

Example: Analyze storage growth over time

The following query analyzes storage growth over the last 30 days:

```
SELECT
    CAST(report_time AS date) AS report_date,
    SUM(storage_bytes) / POWER(1024, 3) AS total_storage_gb
FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics"
WHERE report_time >= current_date - interval '30' day
    AND record_type = 'ACCOUNT'
GROUP BY CAST(report_time AS date)
ORDER BY report_date DESC;
```

Example: Identify incomplete multipart uploads

The following query finds buckets with incomplete multipart uploads older than 7 days:

```
SELECT
    bucket_name,
    SUM(incomplete_mpu_storage_older_than_7_days_bytes) / POWER(1024, 3) AS
 wasted_storage_gb,
    SUM(incomplete_mpu_object_older_than_7_days_count) AS wasted_objects
FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics"
```

```
WHERE report_time = (
    SELECT MAX(report_time)
    FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics"
)
    AND record_type = 'BUCKET'
    AND incomplete_mpu_storage_older_than_7_days_bytes > 0
GROUP BY bucket_name
ORDER BY wasted_storage_gb DESC;
```

Example: Find cold data candidates

The following query identifies prefixes with no activity in the last 100 days that are stored in hot storage tiers:

```
WITH recent_activity AS (
    SELECT DISTINCT
        bucket_name,
        record_value AS prefix_path
    FROM "s3tablescatalog/aws-s3"."lens_my-
config_exp"."expanded_prefixes_activity_metrics"
    WHERE report_time >= current_date - interval '100' day
        AND record_type = 'PREFIX'
        AND all_request_count > 0
)
SELECT
    s.bucket_name,
    s.record_value AS prefix_path,
    s.storage_class,
    SUM(s.storage_bytes) / POWER(1024, 3) AS storage_gb
FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."expanded_prefixes_storage_metrics"
 s
LEFT JOIN recent_activity r
    ON s.bucket_name = r.bucket_name
    AND s.record_value = r.prefix_path
WHERE s.report_time = (
    SELECT MAX(report_time)
    FROM "s3tablescatalog/aws-s3"."lens_my-
config_exp"."expanded_prefixes_storage_metrics"
)
    AND s.record_type = 'PREFIX'
    AND s.storage_class IN ('STANDARD', 'REDUCED_REDUNDANCY')
    AND s.storage_bytes > 1073741824  -- > 1GB
    AND r.prefix_path IS NULL  -- No recent activity
```

```
GROUP BY s.bucket_name, s.record_value, s.storage_class
ORDER BY storage_gb DESC
LIMIT 20;
```

Example: Analyze request patterns

The following query analyzes request patterns to understand access frequency:

```
SELECT
    bucket_name,
    SUM(all_request_count) AS total_requests,
    SUM(get_request_count) AS get_requests,
    SUM(put_request_count) AS put_requests,
    ROUND(100.0 * SUM(get_request_count) / NULLIF(SUM(all_request_count), 0), 2) AS
 get_percentage,
    SUM(downloaded_bytes) / POWER(1024, 3) AS downloaded_gb
FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_activity_metrics"
WHERE report_time >= current_date - interval '7' day
    AND record_type = 'BUCKET'
    AND bucket_name != ''
GROUP BY bucket_name
HAVING SUM(all_request_count) > 0
ORDER BY total_requests DESC
LIMIT 10;
```

Querying with Apache Spark on Amazon EMR

Amazon EMR provides a managed Hadoop framework that makes it easy to process vast amounts of data using Apache Spark. You can use the Iceberg connector to read S3 Storage Lens tables directly.

Read S3 Tables with Spark

Use the following Python code to read S3 Storage Lens data with Spark:

```
from pyspark.sql import SparkSession

spark = SparkSession.builder \
    .appName("S3StorageLensAnalysis") \
    .config("spark.sql.catalog.s3tablescatalog",
 "org.apache.iceberg.spark.SparkCatalog") \
    .config("spark.sql.catalog.s3tablescatalog.catalog-impl",
 "org.apache.iceberg.aws.glue.GlueCatalog") \
```

```
    .getOrCreate()

# Read S3 Storage Lens data
df = spark.read \
    .format("iceberg") \
    .load("s3tablescatalog/aws-s3.lens_my-config_exp.default_storage_metrics")

# Analyze data
df.filter("record_type = 'BUCKET'") \
    .groupBy("bucket_name", "storage_class") \
    .sum("storage_bytes") \
    .orderBy("sum(storage_bytes)", ascending=False) \
    .show(10)
```

Query optimization best practices

Follow these best practices to optimize query performance and reduce costs:

- **Filter by report_time** – Always include date filters to reduce the amount of data scanned. This is especially important for tables with long retention periods.

  ```
  WHERE report_time >= current_date - interval '7' day
  ```

- **Use record_type filters** – Specify the appropriate aggregation level (ACCOUNT, BUCKET, PREFIX) to query only the data you need.

  ```
  WHERE record_type = 'BUCKET'
  ```

- **Include LIMIT clauses** – Use LIMIT for exploratory queries to control result size and reduce query costs.

  ```
  LIMIT 100
  ```

- **Filter empty records** – Use conditions to exclude empty or zero-value records.

  ```
  WHERE storage_bytes > 0
  ```

- **Use the latest data** – When analyzing current state, filter for the most recent report_time to avoid scanning historical data.

  ```
  WHERE report_time = (SELECT MAX(report_time) FROM table_name)
  ```

Example optimized query pattern

The following query demonstrates best practices for optimization:

```
SELECT
    bucket_name,
    SUM(storage_bytes) / POWER(1024, 3) AS storage_gb
FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics"
WHERE report_time >= current_date - interval '7' day  -- Date filter
    AND record_type = 'BUCKET'                         -- Record type filter
    AND storage_bytes > 0                              -- Non-empty filter
    AND bucket_name != ''                              -- Non-empty filter
GROUP BY bucket_name
ORDER BY storage_gb DESC
LIMIT 100;                                             -- Result limit
```

Troubleshooting

Query returns no results

Problem: Your query completes successfully but returns no results.

Solution:

- Verify that data is available by checking the latest report_time:

  ```
  SELECT MAX(report_time) AS latest_data
  FROM "s3tablescatalog/aws-s3"."lens_my-config_exp"."default_storage_metrics";
  ```

- Ensure that you're using the correct namespace name. Use `SHOW TABLES IN \`lens_my-config_exp\`;` to list available tables.
- Wait 24-48 hours after enabling S3 Tables export for the first data to be available.

Access denied errors

Problem: You receive access denied errors when running queries.

Solution: Verify that AWS Lake Formation permissions are correctly configured. For more information, see Integrating Amazon S3 Tables with AWS analytics services.

Using AI assistants with S3 Storage Lens tables

You can use AI assistants and conversational AI tools to interact with your S3 Storage Lens data exported to S3 Tables using natural language. By leveraging the Model Context Protocol (MCP) and the MCP Server for Amazon S3 Tables, you can query, analyze, and gain insights from your storage data without writing SQL queries.

Overview

Model Context Protocol (MCP) is a standardized way for AI applications to access and utilize contextual information. The MCP Server for Amazon S3 Tables provides tools that enable AI assistants to interact with your S3 Tables data using natural language interfaces. This democratizes data access and enables individuals across technical skill levels to work with S3 Storage Lens metrics.

With the MCP Server for S3 Tables, you can use natural language to:

- List S3 table buckets, namespaces, and tables
- Query S3 Storage Lens metrics and get insights
- Analyze storage trends and patterns
- Identify cost optimization opportunities
- Generate reports and visualizations

Supported AI assistants

The MCP Server for S3 Tables works with various AI assistants that support the Model Context Protocol, including:

- **Kiro** - An AI coding assistant with built-in MCP support
- **Amazon Q Developer** - AWS's AI-powered assistant for developers

- **Cline** - An AI coding assistant with MCP integration
- **Claude Desktop** - Anthropic's desktop application with MCP support
- **Cursor** - An AI-powered code editor

> **Important**
>
> AI-generated SQL queries and recommendations should be reviewed and validated before use. Verify that queries are appropriate for your data structure, use case, and performance requirements. Always test recommendations in a non-production environment before implementing them in production.

Setting up Kiro with S3 Storage Lens tables

Kiro is an AI coding assistant that provides seamless integration with S3 Tables through the MCP Server. Kiro can help you install and configure the MCP Server directly through its interface, simplifying the setup process.

For more information about Kiro, see Kiro AI.

Prerequisites

Before you begin, ensure that you have:

- Kiro installed on your system. Download from https://kiro.ai/
- AWS CLI configured with appropriate credentials
- An S3 Storage Lens configuration with S3 Tables export enabled
- Permissions to query S3 Tables. For more information, see Permissions for S3 Storage Lens tables.

Step 1: Install the S3 Tables MCP Server

You can install the S3 Tables MCP Server in two ways:

Option 1: Using Kiro's built-in MCP server management

Kiro can help you discover and install MCP servers directly through its interface:

1. Open Kiro
2. Access the MCP server management interface (typically through settings or command palette)
3. Search for "S3 Tables" or "awslabs.s3-tables-mcp-server"
4. Follow Kiro's prompts to install and configure the server

Option 2: Manual installation using uvx

Alternatively, you can manually install the MCP Server using `uvx`, a Python package runner:

```
uvx awslabs.s3-tables-mcp-server@latest
```

For more information about installing the MCP Server, see the AWS S3 Tables MCP Server documentation.

Step 2: Configure Kiro MCP settings

Create or update your Kiro MCP configuration file at `~/.kiro/settings/mcp.json` with the following content:

```
{
  "mcpServers": {
    "awslabs.s3-tables-mcp-server": {
      "command": "uvx",
      "args": ["awslabs.s3-tables-mcp-server@latest"],
      "env": {
        "AWS_PROFILE": "your-aws-profile",
        "AWS_REGION": "us-east-1"
      }
    }
  }
}
```

Replace `your-aws-profile` with your AWS CLI profile name and `us-east-1` with your AWS Region.

Step 3: Verify the configuration

After configuring the MCP Server, restart Kiro and verify that the S3 Tables tools are available. You can check the available MCP servers in Kiro's settings or by asking Kiro to list available tools.

Example use cases with AI assistants

The following examples demonstrate how to use natural language prompts with AI assistants to interact with S3 Storage Lens data.

Example 1: Query top storage consumers

Prompt: "Show me the top 10 buckets by storage consumption from my S3 Storage Lens data."

The AI assistant will use the MCP Server to query your S3 Storage Lens tables and return the results, including bucket names, storage classes, and storage amounts.

Example 2: Analyze storage growth

Prompt: "Analyze my storage growth over the last 30 days and show me the trend."

The AI assistant will query the storage metrics table, calculate daily storage totals, and present the growth trend.

Example 3: Identify cost optimization opportunities

Prompt: "Find buckets with incomplete multipart uploads older than 7 days that are wasting storage."

The AI assistant will query the storage metrics table for incomplete multipart uploads and provide a list of buckets with potential cost savings.

Example 4: Find cold data candidates

Prompt: "Identify prefixes with no activity in the last 100 days that are stored in hot storage tiers."

The AI assistant will analyze both storage and activity metrics to identify data that could be moved to colder storage tiers for cost optimization.

Example 5: Generate storage reports

Prompt: "Create a summary report of my S3 storage showing total storage, object counts, and request patterns for the last week."

The AI assistant will query multiple tables, aggregate the data, and generate a comprehensive report.

Best practices for using AI assistants

Follow these best practices when using AI assistants with S3 Storage Lens data:

- **Be specific in your prompts** - Provide clear, specific instructions about what data you want to analyze and what insights you're looking for.
- **Verify AI-generated queries** - Always review and validate the SQL queries and recommendations that the AI assistant generates before executing them or taking action. AI assistants may occasionally produce incorrect queries or recommendations that need to be verified against your specific use case and data.
- **Use appropriate permissions** - Ensure that the IAM credentials used by the AI assistant have only the necessary permissions. For read-only analysis, grant only SELECT permissions.
- **Monitor usage** - Track the queries executed by AI assistants using AWS CloudTrail to maintain audit trails.
- **Start with simple queries** - Begin with straightforward queries to understand how the AI assistant interprets your prompts, then progress to more complex analysis.

Logging and traceability

When using the S3 Tables MCP Server with AI assistants, you have multiple ways to audit operations:

- **Local logs** - The MCP Server logs requests and responses locally. You can specify a log directory using the `--log-dir` configuration option.
- **AWS CloudTrail** - All S3 Tables operations via the MCP Server using PyIceberg will have `awslabs/mcp/s3-tables-mcp-server/<version>` as the user agent string. You can filter CloudTrail logs by this user agent to trace actions performed by AI assistants.
- **AI assistant history** - AI assistants like Kiro and Cline maintain history logs that record natural language requests, LLM responses, and instructions provided to the MCP Server.

Security considerations

When using AI assistants with S3 Storage Lens data, follow these security best practices:

- **Use least privilege access** - Grant AI assistants only the minimum permissions required for their tasks.
- **Enable MFA** - Use multi-factor authentication for AWS accounts that AI assistants access.

- **Review permissions regularly** - Periodically audit the permissions granted to AI assistants and revoke unnecessary access.
- **Use separate credentials** - Consider using separate AWS credentials for AI assistant access to facilitate tracking and auditing.
- **Avoid sharing sensitive data** - Be cautious about sharing sensitive information in prompts to AI assistants, especially when using cloud-based AI services.

Troubleshooting

AI assistant cannot connect to S3 Tables

Problem: The AI assistant reports that it cannot connect to S3 Tables or the MCP Server is not responding.

Solution:

- Verify that the MCP Server is correctly installed using `uvx awslabs.s3-tables-mcp-server@latest --version`
- Check that your AWS credentials are configured correctly
- Ensure that the MCP configuration file has the correct AWS profile and region

Access denied errors

Problem: The AI assistant receives access denied errors when querying S3 Storage Lens tables.

Solution:

- Verify that analytics integration is enabled on the `aws-s3` table bucket
- Check that Lake Formation permissions are correctly configured
- Ensure that the AWS credentials have the necessary IAM permissions

Incorrect or unexpected results

Problem: The AI assistant returns incorrect or unexpected results.

Solution:

- Review the SQL query generated by the AI assistant

- Verify that you're using the correct namespace name for your Storage Lens configuration
- Check that data is available by querying the latest report_time
- Refine your prompt to be more specific about what you want to analyze

Using Amazon S3 Storage Lens with AWS Organizations

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use Amazon S3 Storage Lens to collect storage metrics and usage data for all AWS accounts that are part of your AWS Organizations hierarchy. To do this, you must be using AWS Organizations, and you must enable S3 Storage Lens trusted access by using your AWS Organizations management account.

After enabling trusted access, add delegated administrator access to accounts in your organization. The delegated administrator accounts are used to create S3 Storage Lens configurations and dashboards that collect organization-wide storage metrics and user data. For more information about enabling trusted access, see Amazon S3 Storage Lens and AWS Organizations in the *AWS Organizations User Guide*.

Topics

- Enabling trusted access for S3 Storage Lens
- Disabling trusted access for S3 Storage Lens
- Registering a delegated administrator for S3 Storage Lens
- Deregistering a delegated administrator for S3 Storage Lens

Enabling trusted access for S3 Storage Lens

By enabling trusted access, you allow Amazon S3 Storage Lens to access your AWS Organizations hierarchy, membership, and structure through AWS Organizations API operations. S3 Storage Lens then becomes a trusted service for your entire organization's structure.

Whenever a dashboard configuration is created, S3 Storage Lens creates service-linked roles in your organization's management or delegated administrator accounts. The service-linked role grants S3 Storage Lens permission to perform the following actions:

- Describe organizations
- List accounts
- Verify a list of AWS service access for the organizations
- Get delegated administrators for the organizations

S3 Storage Lens can then ensure that it has access to collect the cross-account metrics for the accounts in your organization. For more information, see Using service-linked roles for Amazon S3 Storage Lens.

After enabling trusted access, you can assign delegated administrator access to accounts in your organization. When an account is marked as a delegated administrator for a service, the account receives authorization to access all read-only organization API operations. This access provides the delegated administrator visibility to the members and structures of your organization so that they too can create S3 Storage Lens dashboards.

Note

- Trusted access can only be enabled by the management account.
- Only the management account and delegated administrators can create S3 Storage Lens dashboards or configurations for your organization.

Using the S3 console

To enable S3 Storage Lens to have AWS Organizations trusted access

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

   The **AWS Organizations access** page displays.
5. Choose **Enable** to enable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example shows you how to enable AWS Organizations trusted access for S3 Storage Lens in AWS CLI.

```
aws organizations enable-aws-service-access --service-principal storage-
lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example– Enable AWS Organizations trusted access for S3 Storage Lens using SDK for Java

The following example shows you how to enable trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *`user input placeholders`* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
```

```
import com.amazonaws.services.organizations.model.EnableAWSServiceAccessRequest;

public class EnableOrganizationsTrustedAccess {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.enableAWSServiceAccess(new
 EnableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Disabling trusted access for S3 Storage Lens

Removing an account as a delegated administrator or disabling trusted access limits the account owner's S3 Storage Lens dashboard metrics to work only on an account level. Each account holder is then only be able to see the benefits of S3 Storage Lens through the limited scope of their account, and not their entire organization.

When you disable trusted access in S3 Storage Lens, any dashboards requiring trusted access are no longer updated. Any organizational dashboards that are created are also no longer updated. Instead, you're only able to query historic data for the S3 Storage Lens dashboard, while the data is still available.

Note

- Disabling trusted access for S3 Storage Lens also automatically stops all organization-level dashboards from collecting and aggregating storage metrics. This is because S3 Storage Lens no longer has trusted access to the organization accounts.
- Your management and delegate administrator accounts can still see the historic data for any disabled dashboards. They can also query this historic data while it is still available.

Using the S3 console

To disable trusted access for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

   The **AWS Organizations access** page displays.
5. Choose **Disable** to disable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example disables trusted access for S3 Storage Lens using the AWS CLI.

```
aws organizations disable-aws-service-access --service-principal storage-
lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example– Disable AWS Organizations trusted access for S3 Storage Lens

The following example shows you how to disable AWS Organizations trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.DisableAWSServiceAccessRequest;

public class DisableOrganizationsTrustedAccess {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            // Make sure to remove any existing delegated administrator for S3 Storage
 Lens
            // before disabling access; otherwise, the request will fail.
            organizationsClient.disableAWSServiceAccess(new
 DisableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
```

```
  }
}
```

Registering a delegated administrator for S3 Storage Lens

You can create organization-level dashboards by using your organization's management account or delegated administrator accounts. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can register and deregister other accounts as delegated administrators for the organization.

After enabling trusted access, you can register delegate administrator access to accounts in your organization by using the AWS Organizations REST API, AWS CLI, or SDKs from the management account. (For more information, see RegisterDelegatedAdministrator in the *AWS Organizations API Reference*.) When an account is registered as a delegated administrator, the account receives authorization to access all read-only AWS Organizations API operations. This provides visibility to the members and structures of your organization so that they can create S3 Storage Lens dashboards on your behalf.

> **Note**
>
> Before you can designate a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs, you must call the EnableAWSServiceAccess operation.

Using the S3 console

To register delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose **Register account**.
5. Add an AWS account ID to register the account as a delegated administrator. The delegated administrator is able to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to register Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws organizations register-delegated-administrator --service-principal storage-
lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example– Register Organizations delegated administrators for S3 Storage Lens

The following example shows you how to register AWS Organizations delegated administrators for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
 com.amazonaws.services.organizations.model.RegisterDelegatedAdministratorRequest;

public class RegisterOrganizationsDelegatedAdministrator {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
 delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.registerDelegatedAdministrator(new
 RegisterDelegatedAdministratorRequest()
```

```
                .withAccountId(delegatedAdminAccountId)
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Deregistering a delegated administrator for S3 Storage Lens

After enabling trusted access, you can also deregister delegate administrator access to accounts in your organization. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can deregister accounts as delegated administrators for the organization.

You can deregister a delegated administrator by using the AWS Organizations AWS Management Console, REST API, AWS CLI, or AWS SDKS from the management account. For more information, see DeregisterDelegatedAdministrator in the *AWS Organizations API Reference*.

When an account is deregistered as a delegated administrator, the account loses access to the following:

- All read-only AWS Organizations API operations that provide visibility to the members and structures of your organization.
- All organization-level dashboards created by the delegated administrator. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

> **Note**
>
> The deregistered delegated administrator will still be able to see the historic data for the disabled dashboards that they created if data is still available for querying.

Using the S3 console

To deregister delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose the account that you wish to deregister.
5. Choose **De-register account**. The deregistered account is no longer a delegated administrator and is now unable to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace *111122223333* with your own AWS account ID.

```
aws organizations deregister-delegated-administrator --service-principal storage-
lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example– Deregister Organizations delegated administrators for S3 Storage Lens

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
```

```
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
 com.amazonaws.services.organizations.model.DeregisterDelegatedAdministratorRequest;

public class DeregisterOrganizationsDelegatedAdministrator {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
 delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.deregisterDelegatedAdministrator(new
 DeregisterDelegatedAdministratorRequest()
                .withAccountId(delegatedAdminAccountId)
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Working with S3 Storage Lens groups to filter and aggregate metrics

An Amazon S3 Storage Lens group aggregates metrics using custom filters based on object metadata. Storage Lens groups help you drill down into characteristics of your data, such as distribution of objects by age, your most common file types, and more. For example, you can filter metrics by object tag to identify your fastest-growing datasets, or visualize your storage based on object size and age to inform your storage archive strategy. As a result, Amazon S3 Storage Lens groups helps you to better understand and optimize your S3 storage.

When you use Storage Lens groups, you can analyze and filter S3 Storage Lens metrics using object metadata such as prefixes, suffixes, object tags, object size, or object age. You can also apply a combination of these filters. After you attach your Storage Lens group to your S3 Storage Lens dashboard, you can view S3 Storage Lens metrics aggregated by Amazon S3 Storage Lens groups directly in your dashboard.

For example, you can also filter your metrics by object size or age bands to determine which portion of your storage consists of small objects. You can then use this information with S3 Intelligent-Tiering or S3 Lifecycle to transition small objects to different storage classes for cost and storage optimization.

Topics

- How S3 Storage Lens groups work
- Using Storage Lens groups

How S3 Storage Lens groups work

You can use Storage Lens groups to aggregate metrics using custom filters based on object metadata. When you define a custom filter, you can use prefixes, suffixes, object tags, object sizes, object age, or a combination of these custom filters. During Storage Lens group creation, you can also include a single filter or multiple filter conditions. To specify multiple filter conditions, you use `And` or `Or` logical operators.

When you create and configure a Storage Lens group, the Storage Lens group itself acts as a custom filter in the dashboard that you attach the group to. In your dashboard, you can then use the Storage Lens group filter to obtain storage metrics based on the custom filter that you defined in the group.

To view the data for your Storage Lens group in your S3 Storage Lens dashboard, you must attach the group to the dashboard after you've created the group. After your Storage Lens group is attached to your Storage Lens dashboard, your dashboard will collect storage usage metrics within 48 hours. You can then visualize this data in the Storage Lens dashboard or export it through a metrics export. If you forget to attach a Storage Lens group to a dashboard, your Storage Lens group data won’t be captured or displayed anywhere.

Note

- When you create a S3 Storage Lens group, you're creating an AWS resource. Therefore, each Storage Lens group has its own Amazon Resource Name (ARN), which you can specify when attaching it to or excluding it from a S3 Storage Lens dashboard.
- If your Storage Lens group isn't attached to a dashboard, you won't incur any additional charges for creating a Storage Lens group.
- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.

You can create a Storage Lens group at the account level in a specified home Region (from the list of supported AWS Regions). Then, you can attach your Storage Lens group to multiple Storage Lens dashboards, as long as the dashboards are in the same AWS account and home Region. You can create up to 50 Storage Lens groups per home Region in each AWS account.

You can create and manage S3 Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API.

- AWS resource tags
- Storage Lens groups metrics export

Viewing Storage Lens group aggregated metrics

You can view the aggregated metrics for your Storage Lens groups by attaching the groups to a dashboard. The Storage Lens groups that you want to attach must reside within the designated home Region in the dashboard account.

To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of your dashboard configuration. If you have several Storage Lens

groups, you can filter the **Storage Lens group aggregation** results to include or exclude only the groups that you want. For more information about attaching groups to your dashboards, see the section called "Attach or remove a Storage Lens group".

After you've attached your groups, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

> **Note**
>
> To view aggregated metrics for your Storage Lens group, you must attach the group to an S3 Storage Lens dashboard.

Storage Lens groups permissions

Storage Lens groups require certain permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens group actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to create or delete Storage Lens groups, view their configurations, or manage their tags.

The IAM user or role that you grant permissions to must belong to the account that created or owns the Storage Lens group.

To use Storage Lens groups and to view your Storage Lens groups metrics, you must first have the appropriate permissions to use S3 Storage Lens. For more information, see the section called "Setting permissions".

To create and manage S3 Storage Lens groups, you must have the following IAM permissions, depending on which actions you want to perform:

Action	IAM permissions
Create a new Storage Lens group	`s3:CreateStorageLensGroup`
Create a new Storage Lens group with tags	`s3:CreateStorageLensGroup` , `s3:TagResource`
Update an existing Storage Lens group	`s3:UpdateStorageLensGroup`

Action	IAM permissions
Return the details of a Storage Lens group configuration	`s3:GetStorageLensGroup`
List all Storage Lens groups in your home Region	`s3:ListStorageLensGroups`
Delete a Storage Lens group	`s3:DeleteStorageLensGroup`
List the tags that were added to your Storage Lens group	`s3:ListTagsForResource`
Add or update a Storage Lens group tag for an existing Storage Lens group	`s3:TagResource`
Delete a tag from a Storage Lens group	`s3:UntagResource`

Here's an example of how to configure your IAM policy in the account that creates the Storage Lens group. To use this policy, replace *`us-east-1`* with the home Region that your Storage Lens group is located in. Replace *`111122223333`* with your AWS account ID, and replace *`example-storage-lens-group`* with the name of your Storage Lens group. To apply these permissions to all Storage Lens groups, replace *`example-storage-lens-group`* with an *`*`*.

```
{

    ]
}
```

For more information about S3 Storage Lens permissions, see Setting Amazon S3 Storage Lens permissions. For more information about IAM policy language, see Policies and permissions in Amazon S3.

Storage Lens groups configuration

S3 Storage Lens group name

We recommend giving your Storage Lens groups names that indicate their purpose so that you can easily determine which groups you want to attach to your dashboards. To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of the dashboard configuration.

Storage Lens group names must be unique within the account. They must not exceed 64 characters, and can contain only letters (a-z, A-Z), numbers (0-9), hyphens (-), and underscores (_).

Home Region

The home Region is the AWS Region where your Storage Lens group is created and maintained. Your Storage Lens group is created in the same home Region as your Amazon S3 Storage Lens dashboard. The Storage Lens group configuration and metrics are also stored in this Region. You can create up to 50 Storage Lens groups in a home Region.

After you create your Storage Lens group, you can't edit the home Region.

Scope

To include objects in your Storage Lens group, they must be in scope for your Amazon S3 Storage Lens dashboard. The scope of your Storage Lens dashboard is determined by the buckets that you included in the **Dashboard scope** of your S3 Storage Lens dashboard configuration.

You can use different filters for your objects to define the scope of your Storage Lens group. To view these Storage Lens group metrics in your S3 Storage Lens dashboard, objects must match the filters that you include in your Storage Lens groups. For example, suppose that your Storage Lens

group includes objects with the prefix `marketing` and the suffix `.png`, but no objects match those criteria. In this case, metrics for this Storage Lens group won't be generated in your daily metrics export, and no metrics for this group will be visible in your dashboard.

Filters

You can use the following filters in an S3 Storage Lens group:

- **Prefixes** – Specifies the prefix of included objects, which is a string of characters at the beginning of the object key name. For example, a value of `images` for the **Prefixes** filter includes objects with any of the following prefixes: `images/`, `images-marketing`, and `images/production`. The maximum length of a prefix is 1,024 bytes.
- **Suffixes** – Specifies the suffix of included objects (for example, `.png`, `.jpeg`, or `.csv`). The maximum length of a suffix is 1,024 bytes.
- **Object tags** – Specifies the list of object tags that you want to filter on. A tag key can't exceed 128 Unicode characters, and a tag value can't exceed 256 Unicode characters. Note that if the object tag value field is left empty, S3 Storage Lens groups only matches the object to other objects that also have empty tag values.
- **Age** – Specifies the object age range of included objects in days. Only integers are supported.
- **Size** – Specifies the object size range of included objects in bytes. Only integers are supported. The maximum allowable value is 50 TB.

Storage Lens group object tags

You can Creating a Storage Lens group that includes up to 10 object tag filters. The following example includes two object tag key-value pairs as filters for a Storage Lens group that's named *`Marketing-Department`*. To use this example, replace *`Marketing-Department`* with the name of your group, and replace *`object-tag-key-1`*, *`object-tag-value-1`*, and so on with the object tag key-value pairs that you want to filter on.

```
{
    "Name": "Marketing-Department",
    "Filter": {
     "MatchAnyTag":[
                {
                    "Key": "object-tag-key-1",
                    "Value": "object-tag-value-1"
                },
```

```
                {
                    "Key": "object-tag-key-2",
                    "Value": "object-tag-value-2"
                }
            ]
    }
}
```

Logical operators (And or Or)

To include multiple filter conditions in your Storage Lens group, you can use logical operators (either And or Or). In the following example, the Storage Lens group that's named *Marketing-Department* has an And operator that contains Prefix, ObjectAge, and ObjectSize filters. Because an And operator is used, only objects that match **all** of these filter conditions will be included the Storage Lens group's scope.

To use this example, replace the *user input placeholders* with the values that you want to filter on.

```
{
    "Name": "Marketing-Department",
    "Filter": {
        "And": {
            "MatchAnyPrefix": [
                "prefix-1",
                "prefix-2",
                "prefix-3/sub-prefix-1"
            ],
             "MatchObjectAge": {
                "DaysGreaterThan": 10,
                "DaysLessThan": 60
            },
            "MatchObjectSize": {
                "BytesGreaterThan": 10,
                "BytesLessThan": 60
            }
        }
    }
}
```

> **Note**
>
> If you want to include objects that match **any** of the conditions in the filters, replace the And logical operator with the `Or` logical operator in this example.

AWS resource tags

Each S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (or tags with tag keys that begin with `aws:`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

Storage Lens groups metrics export

S3 Storage Lens group metrics are included in the Amazon S3 Storage Lens metrics export for the dashboard that the Storage Lens group is attached to. For general information about the Storage Lens metrics export feature, see Viewing Amazon S3 Storage Lens metrics using a data export.

Your metrics export for Storage Lens groups includes any S3 Storage Lens metrics that are in scope for the dashboard that you attached the Storage Lens group to. The export also includes additional metrics data for Storage Lens groups.

After you create your Storage Lens group, your metrics export is sent daily to the bucket that you selected when you configured the metrics export for the dashboard that your group is attached to. It can take up to 48 hours for you to receive the first metrics export.

To generate metrics in the daily export, objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you included in your Storage Lens group, then no metrics will be generated. However, if an object matches two or more Storage Lens groups, the object is listed separately for each group when it appears in the metrics export.

You can identify metrics for Storage Lens groups by looking for one of the following values in the `record_type` column of the metrics export for your dashboard:

- `STORAGE_LENS_GROUP_BUCKET`
- `STORAGE_LENS_GROUP_ACCOUNT`

The `record_value` column displays the resource ARN for the Storage Lens group (for example, `arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department`).

Using Storage Lens groups

Amazon S3 Storage Lens groups aggregates metrics using custom filters based on object metadata. You can analyze and filter S3 Storage Lens metrics using prefixes, suffixes, object tags, object size, or object age. With Amazon S3 Storage Lens groups, you can also categorize your usage within and across Amazon S3 buckets. As a result, you'll be able to better understand and optimize your S3 storage.

To start visualizing the data for a Storage Lens group, you must first attach your Storage Lens group to an S3 Storage Lens dashboard. If you need to manage Storage Lens groups in the dashboard, you can edit the dashboard configuration. To check which Storage Lens groups are

under your account, you can list them. To check which Storage Lens groups are attached to your dashboard, you can always check the **Storage Lens groups** tab in the dashboard. To review or update the scope of an existing Storage Lens group, you can view its details. You can also permanently delete a Storage Lens group.

To manage permissions, you can create and add user-defined AWS resource tags to your Storage Lens groups. You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

Creating a Storage Lens group

The following examples demonstrate how to create an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To create a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Storage Lens groups**.
4. Choose **Create Storage Lens group**.
5. Under **General**, view your **Home Region** and enter your **Storage Lens group name**.
6. Under **Scope**, choose the filter that you want to apply to your Storage Lens group. To apply multiple filters, choose your filters, and then choose the **AND** or **OR** logical operator.

   - For the **Prefixes** filter, choose **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
   - For the **Object tags** filter, choose **Object tags**, and enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
   - For the **Suffixes** filter, choose **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
   - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. Then, choose **Specify maximum object age**, and enter the maximum object age.
   - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. Choose **Specify maximum object size**, and enter the maximum object size.
7. (Optional) For AWS resource tags, add the key-value pair, and then choose **Add tag**.
8. Choose **Create Storage Lens group**.

Using the AWS CLI

The following example AWS CLI command creates a Storage Lens group. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

The following example AWS CLI command creates a Storage Lens group with two AWS resource tags. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json \
--tags Key=k1,Value=v1 Key=k2,Value=v2
```

For example JSON configurations, see Storage Lens groups configuration.

Using the AWS SDK for Java

The following AWS SDK for Java example creates a Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

Example– Create a Storage Lens group with a single filter

The following example creates a Storage Lens group named *Marketing-Department*. This group has an object age filter that specifies the age range as *30* to *90* days. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithObjectAge {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupFilter objectAgeFilter = StorageLensGroupFilter.builder()
                    .matchObjectAge(MatchObjectAge.builder()
                            .daysGreaterThan(30)
                            .daysLessThan(90)
```

```
                                .build())
                        .build();

                StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                        .name(storageLensGroupName)
                        .filter(objectAgeFilter)
                        .build();

                CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                        .storageLensGroup(storageLensGroup)
                        .accountId(accountId).build();

                S3ControlClient s3ControlClient = S3ControlClient.builder()
                        .region(Region.US_WEST_2)
                        .credentialsProvider(ProfileCredentialsProvider.create())
                        .build();
                s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
            } catch (AmazonServiceException e) {
                // The call was transmitted successfully, but Amazon S3 couldn't process
                // it and returned an error response.
                e.printStackTrace();
            } catch (SdkClientException e) {
                // Amazon S3 couldn't be contacted for a response, or the client
                // couldn't parse the response from Amazon S3.
                e.printStackTrace();
            }
        }
}
```

Example– Create a Storage Lens group with an AND operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses the AND operator to indicate that objects must match **all** of the filter conditions. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.S3Tag;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupAndOperator;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithAndFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create object tags.
            S3Tag tag1 = S3Tag.builder()
                    .key("object-tag-key-1")
                    .value("object-tag-value-1")
                    .build();
            S3Tag tag2 = S3Tag.builder()
                    .key("object-tag-key-2")
                    .value("object-tag-value-2")
                    .build();

            StorageLensGroupAndOperator andOperator =
 StorageLensGroupAndOperator.builder()
                    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                    .matchAnySuffix(".png", ".gif", ".jpg")
                    .matchAnyTag(tag1, tag2)
                    .matchObjectAge(MatchObjectAge.builder()
                            .daysGreaterThan(30)
                            .daysLessThan(90).build())
                    .matchObjectSize(MatchObjectSize.builder()
                            .bytesGreaterThan(1000L)
                            .bytesLessThan(6000L).build())
                    .build();

            StorageLensGroupFilter andFilter = StorageLensGroupFilter.builder()
                    .and(andOperator)
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
```

```
                    .filter(andFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example– Create a Storage Lens group with an OR operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses an OR operator to apply a prefix filter (*prefix-1*, *prefix-2*, *prefix3/sub-prefix-1*) or an object size filter with a size range between *1000* bytes and *6000* bytes. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
```

```
import software.amazon.awssdk.services.s3control.model.StorageLensGroupOrOperator;

public class CreateStorageLensGroupWithOrFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupOrOperator orOperator =
 StorageLensGroupOrOperator.builder()
                    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                    .matchObjectSize(MatchObjectSize.builder()
                            .bytesGreaterThan(1000L)
                            .bytesLessThan(6000L)
                            .build())
                    .build();

            StorageLensGroupFilter orFilter = StorageLensGroupFilter.builder()
                    .or(orOperator)
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(orFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
```

```
        }
    }
}
```

Example– Create a Storage Lens group with a single filter and two AWS resource tags

The following example creates a Storage Lens group named *Marketing-Department* that has a suffix filter. This example also adds two AWS resource tags to the Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.Tag;

public class CreateStorageLensGroupWithResourceTags {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create AWS resource tags.
            Tag resourceTag1 = Tag.builder()
                    .key("resource-tag-key-1")
                    .value("resource-tag-value-1")
                    .build();
            Tag resourceTag2 = Tag.builder()
                    .key("resource-tag-key-2")
                    .value("resource-tag-value-2")
                    .build();

            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
                    .matchAnySuffix(".png", ".gif", ".jpg")
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
```

```
                    .name(storageLensGroupName)
                    .filter(suffixFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
                    .tags(resourceTag1, resourceTag2)
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

For example JSON configurations, see Storage Lens groups configuration.

Attaching or removing S3 Storage Lens groups to or from your dashboard

After you've upgraded to the advanced tier in Amazon S3 Storage Lens, you can attach a Storage Lens group to your dashboard. If you have several Storage Lens groups, you can include or exclude the groups that you want.

Your Storage Lens groups must reside within the designated home Region in the dashboard account. After you attach a Storage Lens group to your dashboard, you'll receive the additional Storage Lens group aggregation data in your metrics export within 48 hours.

> **Note**
>
> If you want to view aggregated metrics for your Storage Lens group, you must attach it to your Storage Lens dashboard. For examples of Storage Lens group JSON configuration files, see S3 Storage Lens example configuration with Storage Lens groups in JSON.

Using the S3 console

To attach a Storage Lens group to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to attach a Storage Lens group to.
4. Choose **Edit**.
5. Under **Metrics selection**, choose **Advanced metrics and recommendations**.
6. Select **Storage Lens group aggregation**.

   > **Note**
   >
   > By default, **Advanced metrics** is also selected. However, you can also deselect this setting as it's not required to aggregate Storage Lens groups data.

7. Scroll down to **Storage Lens group aggregation** and specify the Storage Lens group or groups that you either want to include or exclude in the data aggregation. You can use the following filtering options:

   - If you want to include certain Storage Lens groups, choose **Include Storage Lens groups**. Under **Storage Lens groups to include**, select your Storage Lens groups.
   - If you want to include all Storage Lens groups, select **Include all Storage Lens groups in home Region in this account**.
   - If you want to exclude certain Storage Lens groups, choose **Exclude Storage Lens groups**. Under **Storage Lens groups to exclude**, select the Storage Lens groups that you want to exclude.

8. Choose **Save changes**. If you've configured your Storage Lens groups correctly, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

To remove a Storage Lens group from an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to remove a Storage Lens group from.
4. Choose **View dashboard configuration**.
5. Choose **Edit**.
6. Scroll down to the **Metrics selection** section.
7. Under **Storage Lens group aggregation**, choose the **X** next to the Storage Lens group that you want to remove. This removes your Storage Lens group.

   If you included all of your Storage Lens groups in your dashboard, clear the check box next to **Include all Storage Lens groups in home Region in this account**.
8. Choose **Save changes**.

> **Note**
>
> It will take up to 48 hours for your dashboard to reflect the configuration updates.

Using the AWS SDK for Java

Example– Attach all Storage Lens groups to a dashboard

The following SDK for Java example attaches all Storage Lens groups in the account *111122223333* to the *DashBoardConfigurationId* dashboard:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3control.AWSS3Control;
```

```
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWithStorageLensGroups {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel();

            AccountLevel accountLevel = new AccountLevel()
                    .withBucketLevel(new BucketLevel())
                    .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfiguration(new
 PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
```

```
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example– Attach two Storage Lens groups to a dashboard

The following AWS SDK for Java example attaches two Storage Lens groups (*StorageLensGroupName1* and *StorageLensGroupName2*) to the *ExampleDashboardConfigurationId* dashboard.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroups {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
 StorageLensGroupLevelSelectionCriteria()
                    .withInclude(
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
 + ":storage-lens-group/" + storageLensGroupName1,
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
 + ":storage-lens-group/" + storageLensGroupName2);
```

```
            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
                    .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                    .withBucketLevel(new BucketLevel())
                    .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfiguration(new
 PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example– Attach all Storage Lens groups with exclusions

The following SDK for Java example attaches all Storage Lens groups to the *ExampleDashboardConfigurationId* dashboard, excluding the two specified (*StorageLensGroupName1* and *StorageLensGroupName2*):

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroupsExcluded {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
 StorageLensGroupLevelSelectionCriteria()
                    .withInclude(
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
 + ":storage-lens-group/" + storageLensGroupName1,
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
 + ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
                    .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                    .withBucketLevel(new BucketLevel())
                    .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
```

```
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfiguration(new
 PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Visualizing your Storage Lens groups data

You can visualize your Storage Lens groups data by attaching the group to your Amazon S3 Storage Lens dashboard. After you've included the Storage Lens group in the Storage Lens group aggregation in your dashboard configuration, it can take up to 48 hours for the Storage Lens group data to display in your dashboard.

After the dashboard configuration has been updated, any newly attached Storage Lens groups appear in the list of available resources under the **Storage Lens groups** tab. You can also further analyze storage usage in your **Overview** tab by slicing the data by another dimension. For example, you can choose one of the items listed under the **Top 3** categories and choose **Analyze by** to slice the data by another dimension. You can't apply the same dimension as the filter itself.

> **Note**
>
> You can't apply a Storage Lens group filter along with a prefix filter, or the reverse. You also can't further analyze a Storage Lens group by using a prefix filter.

You can use the **Storage Lens groups** tab in the Amazon S3 Storage Lens dashboard to customize the data visualization for the Storage Lens groups that are attached to your dashboard. You can either visualize the data for some Storage Lens groups that are attached to your dashboard, or all of them.

When visualizing Storage Lens group data in your S3 Storage Lens dashboard, be aware of the following:

- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.
- Objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you include in your Storage Lens group, then no metrics are generated. To determine if there are any unassigned objects, check your total object count in the dashboard at the account level and bucket level.

Updating a Storage Lens group

The following examples demonstrate how to update an Amazon S3 Storage Lens group. You can update a Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **Scope**, choose **Edit**.

5. On the **Scope** page, select the filter that you want to apply to your Storage Lens group. To apply multiple filters, select your filters, and choose the **AND** or **OR** logical operator.

   - For the **Prefixes** filter, select **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
   - For the **Object tags** filter, enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
   - For the **Suffixes** filter, select **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
   - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. For **Specify maximum object age**, enter the maximum object age.
   - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. For **Specify maximum object size**, enter the maximum object size.

6. Choose **Save changes**. The details page for the Storage Lens group appears.
7. (Optional) If you want to add a new AWS resource tag, scroll to the **AWS resource tags** section, then choose **Add tags**. The **Add tags** page appears.

   Add the new key-value pair, then choose **Save changes**. The details page for the Storage Lens group appears.
8. (Optional) If you want to remove an existing AWS resource tag, scroll to the **AWS resource tags** section, and select the resource tag. Then, choose **Delete**. The **Delete AWS tags** dialog box appears.

   Choose **Delete** again to permanently delete the AWS resource tag.

   > **Note**
   >
   > After you permanently delete an AWS resource tag, it can't be restored.

Using the AWS CLI

The following AWS CLI example command returns the configuration details for a Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

The following AWS CLI example updates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control update-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

For example JSON configurations, see Storage Lens groups configuration.

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the *Marketing-Department* Storage Lens group in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;

public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            GetStorageLensGroupRequest getRequest =
 GetStorageLensGroupRequest.builder()
```

```
                    .name(storageLensGroupName)
                    .accountId(accountId).build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            GetStorageLensGroupResponse response =
 s3ControlClient.getStorageLensGroup(getRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

The following example updates the Storage Lens group named *Marketing-Department* in account *111122223333*. This example updates the dashboard scope to include objects that match any of the following suffixes: *.png*, *.gif*, *.jpg*, or *.jpeg*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.UpdateStorageLensGroupRequest;

public class UpdateStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
```

```
            // Create updated filter.
            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
                    .matchAnySuffix(".png", ".gif", ".jpg", ".jpeg")
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(suffixFilter)
                    .build();

            UpdateStorageLensGroupRequest updateStorageLensGroupRequest =
 UpdateStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .storageLensGroup(storageLensGroup)
                    .accountId(accountId)
                    .build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.updateStorageLensGroup(updateStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

For example JSON configurations, see Storage Lens groups configuration.

Managing AWS resource tags with Storage Lens groups

Each Amazon S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with `aws:`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens groups.

Topics

- Adding an AWS resource tag to a Storage Lens group
- Updating Storage Lens group tag values
- Deleting an AWS resource tag from a Storage Lens group
- Listing Storage Lens group tags

Adding an AWS resource tag to a Storage Lens group

The following examples demonstrate how to add AWS resource tags to an Amazon S3 Storage Lens group. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add an AWS resource tag to a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, choose **Add tags**.
5. On the **Add tags** page, add the new key-value pair.

> **Note**
>
> Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens group.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command adds two resource tags to an existing Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-department \
--region us-east-1 --tags Key=k1,Value=v1 Key=k2,Value=v2
```

Using the AWS SDK for Java

The following AWS SDK for Java example adds two AWS resource tags to an existing Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class TagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                    .key("resource-tag-key-2")
                    .value("resource-tag-value-2")
                    .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .tags(resourceTag1, resourceTag2)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
```

```
    }
}
```

Updating Storage Lens group tag values

The following examples demonstrate how to update Storage Lens group tag values by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the tag that you want to update.
5. Add the new tag value, using the same key of the key-value pair that you want to update. Choose the checkmark icon to update the tag value.

   > **Note**
   >
   > Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) If you want to add new tags, choose **Add tag** to add new entries. The **Add tags** page appears.

   You can add up to 50 AWS resource tags for your Storage Lens group. When you're finished adding new tags, choose **Save changes**.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove. When you're finished removing tags, choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command updates two tag values for the Storage Lens group named *`marketing-department`*. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
--region us-east-1 --tags Key=k1,Value=v3 Key=k2,Value=v4
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates two Storage Lens group tag values. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class UpdateTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag updatedResourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-updated-value-1")
                .build();
            Tag updatedResourceTag2 = Tag.builder()
                    .key("resource-tag-key-2")
                    .value("resource-tag-updated-value-2")
                    .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .tags(updatedResourceTag1, updatedResourceTag2)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
```

```
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting an AWS resource tag from a Storage Lens group

The following examples demonstrate how to delete an AWS resource tag from a Storage Lens group. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete an AWS resource tag from a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the key-value pair that you want to delete.
5. Choose **Delete**. The **Delete AWS resource tags** dialog box appears.

   > **Note**
   >
   > If tags are used to control access, proceeding with this action can affect related resources. After you permanently delete a tag, it can't be restored.

6. Choose **Delete** to permanently delete the key-value pair.

Using the AWS CLI

The following AWS CLI command deletes two AWS resource tags from an existing Storage Lens group: To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control untag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-
Department \
--region us-east-1 --tag-keys k1 k2
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes two AWS resource tags from the Storage Lens group Amazon Resource Name (ARN) that you specify in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;

public class UntagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            String tagKey1 = "resource-tag-key-1";
            String tagKey2 = "resource-tag-key-2";
            UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .tagKeys(tagKey1, tagKey2)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
```

```
                    .build();
            s3ControlClient.untagResource(untagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Listing Storage Lens group tags

The following examples demonstrate how to list the AWS resource tags associated with a Storage Lens group. You can list tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To review the list of tags and tag values for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you're interested in.
4. Scroll down to the **AWS resource tags** section. All of the user-defined AWS resource tags that are added to your Storage Lens group are listed along with their tag values.

Using the AWS CLI

The following AWS CLI example command lists all the Storage Lens group tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-tags-for-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
```

```
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens group tag values for the Storage Lens group Amazon Resource Name (ARN) that you specify. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            ListTagsForResourceRequest listTagsForResourceRequest =
 ListTagsForResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            ListTagsForResourceResponse response =
 s3ControlClient.listTagsForResource(listTagsForResourceRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
```

```
            e.printStackTrace();
        }
    }
}
```

Listing all Storage Lens groups

The following examples demonstrate how to list all Amazon S3 Storage Lens groups in an AWS account and home Region. These examples show how list all Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To list all Storage Lens groups in an account and home Region

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, the list of Storage Lens groups in your account is displayed.

Using the AWS CLI

The following AWS CLI example lists all of the Storage Lens groups for your account. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control list-storage-lens-groups --account-id 111122223333 \
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens groups for account *`111122223333`*. To use this example, replace the *`user input placeholders`* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsRequest;
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsResponse;

public class ListStorageLensGroups {
    public static void main(String[] args) {
        String accountId = "111122223333";

        try {
            ListStorageLensGroupsRequest listStorageLensGroupsRequest =
 ListStorageLensGroupsRequest.builder()
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            ListStorageLensGroupsResponse response =
 s3ControlClient.listStorageLensGroups(listStorageLensGroupsRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Viewing Storage Lens group details

The following examples demonstrate how to view Amazon S3 Storage Lens group configuration details. You can view these details by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To view Storage Lens group configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you're interested in.
4. Choose **View details**. You can now review the details of your Storage Lens group.

Using the AWS CLI

The following AWS CLI example returns the configuration details for a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;

public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            GetStorageLensGroupRequest getRequest =
 GetStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .accountId(accountId).build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
```

```
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            GetStorageLensGroupResponse response =
 s3ControlClient.getStorageLensGroup(getRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting a Storage Lens group

The following examples demonstrate how to delete an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you want to delete.
4. Choose **Delete**. A **Delete Storage Lens group** dialog box displays.
5. Choose **Delete** again to permanently delete your Storage Lens group.

> **Note**
>
> After you delete a Storage Lens group, it can't be restored.

Using the AWS CLI

The following AWS CLI example deletes the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.DeleteStorageLensGroupRequest;

public class DeleteStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            DeleteStorageLensGroupRequest deleteStorageLensGroupRequest =
 DeleteStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .accountId(accountId).build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.deleteStorageLensGroup(deleteStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
```

```
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Cataloging and analyzing your data with S3 Inventory

You can use Amazon S3 Inventory to help manage your storage. For example, you can use it to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also simplify and speed up business workflows and big data jobs by using Amazon S3 Inventory, which provides a scheduled alternative to the Amazon S3 synchronous `List` API operations. Amazon S3 Inventory does not use the `List` API operations to audit your objects and does not affect the request rate of your bucket.

Amazon S3 Inventory provides comma-separated values (CSV), Apache optimized row columnar (ORC) or Apache Parquet output files that list your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or objects with a shared prefix (that is, objects that have names that begin with a common string). If you set up a weekly inventory, a report is generated every Sunday (UTC time zone) after the initial report. For information about Amazon S3 Inventory pricing, see Amazon S3 pricing.

You can configure multiple inventory lists for a bucket. When you're configuring an inventory list, you can specify the following:

- What object metadata to include in the inventory
- Whether to list all object versions or only current versions
- Where to store the inventory list file output
- Whether to generate the inventory on a daily or weekly basis
- Whether to encrypt the inventory list file

You can query Amazon S3 Inventory with standard SQL queries by using Amazon Athena, Amazon Redshift Spectrum, and other tools, such as Presto, Apache Hive, and Apache Spark. For more information about using Athena to query your inventory files, see the section called “Querying inventory with Athena”.

> **Note**
>
> It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

> **Note**
>
> After deleting an inventory configuration, Amazon S3 might still deliver one additional inventory report during a brief transition period while the system processes the deletion.

Source and destination buckets

The bucket that the inventory lists objects for is called the *source bucket*. The bucket where the inventory list file is stored is called the *destination bucket*.

Source bucket

The inventory lists the objects that are stored in the source bucket. You can get an inventory list for an entire bucket, or you can filter the list by object key name prefix.

The source bucket:

- Contains the objects that are listed in the inventory
- Contains the configuration for the inventory

Destination bucket

Amazon S3 Inventory list files are written to the destination bucket. To group all the inventory list files in a common location in the destination bucket, you can specify a destination prefix in the inventory configuration.

The destination bucket:

- Contains the inventory file lists.
- Contains the manifest files that list all the inventory list files that are stored in the destination bucket. For more information, see Inventory manifest.
- Must have a bucket policy to give Amazon S3 permission to verify ownership of the bucket and permission to write files to the bucket.

- Must be in the same AWS Region as the source bucket.
- Can be the same as the source bucket.
- Can be owned by a different AWS account than the account that owns the source bucket.

Amazon S3 Inventory list

An inventory list file contains a list of the objects in the source bucket and metadata for each object. An inventory list file is stored in the destination bucket with one of the following formats:

- As a CSV file compressed with GZIP
- As an Apache optimized row columnar (ORC) file compressed with ZLIB
- As an Apache Parquet file compressed with Snappy

> **Note**
>
> Objects in Amazon S3 Inventory reports aren't guaranteed to be sorted in any order.

An inventory list file contains a list of the objects in the source bucket and metadata for each listed object. The following fields are always included:

- **Bucket name** – The name of the bucket that the inventory is for.
- **Key name** – The object key name (or key) that uniquely identifies the object in the bucket. When you're using the CSV file format, the key name is URL-encoded and must be decoded before you can use it.

You can choose to include the following additional metadata fields in the report:

- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see Object in the *Amazon Simple Storage Service API Reference*.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.

- **Storage class** – The storage class that's used for storing the object. Set to `STANDARD`, `REDUCED_REDUNDANCY`, `STANDARD_IA`, `ONEZONE_IA`, `INTELLIGENT_TIERING`, `GLACIER`, `DEEP_ARCHIVE`, `OUTPOSTS`, `GLACIER_IR`, `SNOW`, or `EXPRESS_ONEZONE`. For more information, see Understanding and managing Amazon S3 storage classes.
- **Checksum algorithm** – Indicates the algorithm that's used to create the checksum for the object. For more information, see Using supported checksum algorithms.
- **Encryption status** – The server-side encryption status, depending on what kind of encryption key is used— server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). Set to `SSE-S3`, `SSE-KMS`, `DSSE-KMS`, `SSE-C`, or `NOT-SSE`. A status of `NOT-SSE` means that the object is not encrypted with server-side encryption. For more information, see Protecting data with encryption.
- **S3 Intelligent-Tiering access tier** – Access tier (frequent or infrequent) of the object if it is stored in the S3 Intelligent-Tiering storage class. Set to `FREQUENT`, `INFREQUENT`, `ARCHIVE_INSTANT_ACCESS`, `ARCHIVE`, or `DEEP_ARCHIVE`. For more information, see Storage class for automatically optimizing data with changing or unknown access patterns.
- **S3 Intelligent-Tiering reference date** – The date that S3 Intelligent-Tiering uses to determine tier-transition eligibility for an object in the S3 Intelligent-Tiering storage class. This date reflects when the object was last considered active for tiering purposes. Amazon S3 sets this date from the object's creation date for objects created directly in S3 Intelligent-Tiering and never accessed, its transition date for objects transitioned into S3 Intelligent-Tiering and never accessed, or its most recent access date for objects accessed by a `GET`, `PUT`, `RESTORE`, or `SELECT` request. This field is empty for objects that aren't stored in the S3 Intelligent-Tiering storage class, and for objects smaller than 128 KB, which S3 Intelligent-Tiering doesn't monitor. For more information, see Storage class for automatically optimizing data with changing or unknown access patterns.

> **Note**
>
> The S3 Intelligent-Tiering reference date tracks object access on a best-effort basis and might not capture every access event, similar to Amazon S3 server access logs. As a result, the reference date might not reflect the most recent access to an object.

> **Note**
>
> A SELECT (SelectObjectContent) request updates the reference date and keeps an object out of the asynchronous Archive Access and Deep Archive Access tiers, but unlike a GET it doesn't move the object back to the Frequent Access tier or stop it tiering down to Infrequent Access or Archive Instant Access. An object accessed recently by SELECT can therefore show a recent reference date while remaining in Infrequent Access or Archive Instant Access. For more information, see How S3 Intelligent-Tiering works.

- **S3 Object Lock retain until date** – The date until which the locked object cannot be deleted. For objects with an active event hold, this date is dynamic, based on the report generation time. For objects with a released event hold or fixed retention, this date is fixed. For more information, see Locking objects with Object Lock.
- **S3 Object Lock retention mode** – Set to GOVERNANCE or COMPLIANCE for objects that are locked. For more information, see Locking objects with Object Lock.
- **S3 Object Lock legal hold status** – Set to ON if a legal hold has been applied to an object. Otherwise, it is set to OFF. For more information, see Locking objects with Object Lock.
- **S3 Object Lock event hold status** – Set to ON or OFF, reflecting the event hold status of the object. This field is empty when the object has no event hold configured.
- **S3 Object Lock event hold duration** – The variable retention duration that is configured for the object. This field is empty when the object has no event hold configured.

> **Note**
>
> When you include the S3 Object Lock event hold duration field, the report also includes an S3 Object Lock event hold duration unit column (DAYS or YEARS) to express the unit of the duration value.

- **Version ID** – The object version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see Retaining multiple versions of objects with S3 Versioning. (This field is not included if the list is configured only for the current version of the objects.)
- **IsLatest** – Set to True if the object is the current version of the object. (This field is not included if the list is configured only for the current version of the objects.)

- **Delete marker** – Set to `True` if the object is a delete marker. For more information, see Retaining multiple versions of objects with S3 Versioning. (This field is automatically added to your report if you've configured the report to include all versions of your objects).
- **Multipart upload flag** – Set to `True` if the object was uploaded as a multipart upload. For more information, see Uploading and copying objects using multipart upload in Amazon S3.
- **Object owner** – The canonical user ID of the owner of the object. For more information, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.
- **Replication status** – Set to `PENDING`, `COMPLETED`, `FAILED`, or `REPLICA`. For more information, see Getting replication status information.
- **S3 Bucket Key status** – Set to `ENABLED` or `DISABLED`. Indicates whether the object uses an S3 Bucket Key for SSE-KMS. For more information, see Using Amazon S3 Bucket Keys.
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. The Object ACL field is defined in JSON format. An S3 Inventory report includes ACLs that are associated with objects in your source bucket, even when ACLs are disabled for the bucket. For more information, see Working with the Object ACL field and Access control list (ACL) overview.

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.
For example, suppose that you have the following Object ACL field in JSON format:

```
{
        "version": "2022-11-10",
        "status": "AVAILABLE",
        "grants": [{
            "canonicalId": "example-canonical-user-ID",
            "type": "CanonicalUser",
            "permission": "READ"
        }]
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQUlMQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2Fs
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see Querying Amazon S3 Inventory with Amazon Athena.

- **Lifecycle Expiration Date** – Set to the lifecycle expiration timestamp of the object. This field will only be populated, if the object is to be expired by an applicable lifecycle rule. In other cases, the field will be empty. Objects with `FAILED` replication status will not have an expiration date populated, as S3 Lifecycle prevents expiration and transition actions on these objects until replication has succeeded. For more information, see Expiring objects.

Note

When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. The inventory report includes the objects that have expired but haven't been removed yet. For more information about expiration actions in S3 Lifecycle, see Expiring objects.

The following is an example inventory report with additional metadata fields consisting of four records.

```
amzn-s3-demo-bucket1    example-object-1    EXAMPLEDC8l.XJCENlF7LePaNIIvs001    TRUE

    EXAMPLE766e8f6b115d93d41df2eac420aa4a465d177c1398bc6a088c76b7003
```

We recommend that you create a lifecycle policy that deletes old inventory lists. For more information, see Managing the lifecycle of objects.

The `s3:PutInventoryConfiguration` permission allows a user to both select all the metadata fields that are listed earlier for each object when configuring an inventory list and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory list. To restrict access to an inventory report, see Grant permissions for S3 Inventory and S3 analytics.

Inventory consistency

All of your objects might not appear in each inventory list. The inventory list provides eventual consistency for PUT requests (of both new objects and overwrites) and for DELETE requests. Each inventory list for a bucket is a snapshot of bucket items. These lists are eventually consistent (that is, a list might not include recently added or deleted objects).

To validate the state of an object before you take action on the object, we recommend that you perform a `HeadObject` REST API request to retrieve metadata for the object, or to check the object's properties in the Amazon S3 console. You can also check object metadata with the AWS CLI or the AWS SDKS. For more information, see `HeadObject` in the *Amazon Simple Storage Service API Reference*.

For more information about working with Amazon S3 Inventory, see the following topics.

Topics

- Configuring Amazon S3 Inventory
- Locating your inventory list

- Converting empty version ID strings in Amazon S3 Inventory reports to null strings

- Working with the Object ACL field

Configuring Amazon S3 Inventory

Amazon S3 Inventory provides a flat file list of your objects and metadata, on a schedule that you define. You can use S3 Inventory as a scheduled alternative to the Amazon S3 synchronous `List` API operation. S3 Inventory provides comma-separated values (CSV), Apache optimized row columnar (ORC), or Apache Parquet (Parquet) output files that list your objects and their corresponding metadata.

You can configure S3 Inventory to create inventory lists on a daily or weekly basis for an S3 bucket or for objects that share a prefix (objects that have names that begin with the same string). For more information, see Cataloging and analyzing your data with S3 Inventory.

This section describes how to configure an inventory, including details about the inventory source and destination buckets.

Topics

- Overview
- Creating a destination bucket policy
- Granting Amazon S3 permission to use your customer managed key for encryption
- Configuring inventory by using the S3 console
- Using the REST API to work with S3 Inventory

Overview

Amazon S3 Inventory helps you manage your storage by creating lists of the objects in an S3 bucket on a defined schedule. You can configure multiple inventory lists for a bucket. The inventory lists are published to CSV, ORC, or Parquet files in a destination bucket.

The easiest way to set up an inventory is by using the Amazon S3 console, but you can also use the Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. The console performs the first step of the following procedure for you: adding a bucket policy to the destination bucket.

To set up Amazon S3 Inventory for an S3 bucket

1. **Add a bucket policy for the destination bucket.**

You must create a bucket policy on the destination bucket that grants permissions to Amazon S3 to write objects to the bucket in the defined location. For an example policy, see Grant permissions for S3 Inventory and S3 analytics.

2. **Configure an inventory to list the objects in a source bucket and publish the list to a destination bucket.**

   When you configure an inventory list for a source bucket, you specify the destination bucket where you want the list to be stored, and whether you want to generate the list daily or weekly. You can also configure whether to list all object versions or only current versions and what object metadata to include.

   Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key.

   For more information about the optional metadata fields available in S3 Inventory, see OptionalFields in the *Amazon Simple Storage Service API Reference*. For more information about restricting access to certain optional metadata fields in an inventory configuration, see Control S3 Inventory report configuration creation.

   You can specify that the inventory list file be encrypted by using server-side encryption with an Amazon S3 managed key (SSE-S3) or an AWS Key Management Service (AWS KMS) customer managed key (SSE-KMS).

   > **Note**
   >
   > The AWS managed key (`aws/s3`) is not supported for SSE-KMS encryption with S3 Inventory.

   For more information about SSE-S3 and SSE-KMS, see Protecting data with server-side encryption. If you plan to use SSE-KMS encryption, see Step 3.

   - For information about how to use the console to configure an inventory list, see Configuring inventory by using the S3 console.

- To use the Amazon S3 API to configure an inventory list, use the PutBucketInventoryConfiguration REST API operation or the equivalent from the AWS CLI or AWS SDKs.

3. **To encrypt the inventory list file with SSE-KMS, grant Amazon S3 permission to use the AWS KMS key.**

   You can configure encryption for the inventory list file by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, or AWS SDKs. Whichever way you choose, you must grant Amazon S3 permission to use the customer managed key to encrypt the inventory file. You grant Amazon S3 permission by modifying the key policy for the customer managed key that you want to use to encrypt the inventory file. Make sure that you've provided a KMS key ARN in the S3 Inventory configuration or the destination bucket's encryption settings. If no KMS key ARN has been specified and the default encryption settings are being used, you won't be able to access your S3 Inventory report.

   The destination bucket that stores the inventory list file can be owned by a different AWS account than the account that owns the source bucket. If you use SSE-KMS encryption for the cross-account operations of Amazon S3 Inventory, we recommend that you use a fully qualified KMS key ARN when you configure S3 inventory. For more information, see Using SSE-KMS encryption for cross-account operations and ServerSideEncryptionByDefault in the *Amazon Simple Storage Service API Reference*.

   > **Note**
   >
   > If you can't access your S3 Inventory report, use the GetBucketEncryption API, and check whether the destination bucket has the default SSE-KMS encryption enabled. If no KMS key ARN has been specified and the default encryption settings are being used, you won't be able to access your S3 Inventory report. To access S3 Inventory reports again, either provide a KMS key ARN in the S3 Inventory configuration or in the destination bucket's encryption settings.

> **Directory buckets**
>
> S3 Inventory is supported for directory buckets. When configuring S3 Inventory for a directory bucket, note the following differences:

- **Permissions** – For directory buckets, you must use the `s3express:PutInventoryConfiguration` and `s3express:GetInventoryConfiguration` permissions in an IAM identity-based policy instead of a bucket policy. These permissions use the `s3express:` namespace rather than the `s3:` namespace used for general purpose buckets. For more information, see Authorizing Regional endpoint API operations with IAM.
- **Supported optional fields** – The following optional fields are supported for directory buckets: `Size`, `LastModifiedDate`, `StorageClass`, `ETag`, `IsMultipartUploaded`, `EncryptionStatus`, `BucketKeyStatus`, `ChecksumAlgorithm`, and `LifecycleExpirationDate`.
- **Condition key** – For directory buckets, use the `s3express:InventoryAccessibleOptionalFields` condition key to control access to optional metadata fields in inventory reports.

Creating a destination bucket policy

If you create your inventory configuration through the Amazon S3 console, Amazon S3 automatically creates a bucket policy on the destination bucket that grants Amazon S3 write permission to the bucket. However, if you create your inventory configuration through the AWS CLI, AWS SDKs, or the Amazon S3 REST API, you must manually add a bucket policy on the destination bucket. The S3 Inventory destination bucket policy allows Amazon S3 to write data for the inventory reports to the bucket.

The following is the example bucket policy.

JSON

```
{
      "Version":"2012-10-17",
      "Statement": [
        {
            "Sid": "InventoryExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
```

```
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
            ],
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

For more information, see Grant permissions for S3 Inventory and S3 analytics.

Directory buckets

For directory buckets, you must manually add a destination bucket policy. The destination bucket policy uses a different service principal and ARN format than general purpose buckets. Specify `s3express.amazonaws.com` as the service principal, and use the directory bucket ARN format for the source bucket. The following example shows a destination bucket policy for directory buckets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "InventoryExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3express.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
            ],
            "Condition": {
```

```
                "ArnLike": {
                    "aws:SourceARN": "arn:aws:s3express:us-
west-2:111122223333:bucket/DOC-EXAMPLE-SOURCE-BUCKET--zone-id--x-s3"
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

If an error occurs when you try to create the bucket policy, you are given instructions on how to fix it. For example, if you choose a destination bucket in another AWS account and don't have permissions to read and write to the bucket policy, you see an error message.

In this case, the destination bucket owner must add the bucket policy to the destination bucket. If the policy is not added to the destination bucket, you won't get an inventory report because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, the correct account ID of the source bucket owner must be substituted in the policy.

Note

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see Why can't I generate an Amazon S3 Inventory Report? .

Granting Amazon S3 permission to use your customer managed key for encryption

To grant Amazon S3 permission to use your AWS Key Management Service (AWS KMS) customer managed key for server-side encryption, you must use a key policy. To update your key policy so that you can use your customer managed key, use the following procedure.

To grant Amazon S3 permissions to encrypt by using your customer managed key

1. Using the AWS account that owns the customer managed key, sign into the AWS Management Console.
2. Open the AWS KMS console at https://console.aws.amazon.com/kms.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the customer managed key that you want to use to encrypt your inventory files.
6. In the **Key policy** section, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. On the **Edit key policy** page, add the following lines to the existing key policy. For *source-account-id* and *amzn-s3-demo-source-bucket*, supply the appropriate values for your use case.

```
{
    "Sid": "Allow Amazon S3 use of the customer managed key",
    "Effect": "Allow",
    "Principal": {
        "Service": "s3.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition":{
      "StringEquals":{
         "aws:SourceAccount":"source-account-id"
     },
      "ArnLike":{
        "aws:SourceARN": "arn:aws:s3:::amzn-s3-demo-source-bucket"
     }
   }
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following links in the *AWS Key Management Service Developer Guide*:

- Managing keys
- Key policies in AWS KMS

Directory buckets

For directory buckets, the KMS key policy uses a different service principal and source ARN format than general purpose buckets. Specify `s3express.amazonaws.com` as the service principal, and use the directory bucket ARN format for the source ARN. The following example shows the key policy statement for directory buckets.

```
{
    "Sid": "Allow S3 Express use of the KMS key",
    "Effect": "Allow",
    "Principal": {
        "Service": "s3express.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "source-account-id"
        },
        "ArnLike": {
            "aws:SourceARN": "arn:aws:s3express:region:source-account-
id:bucket/DOC-EXAMPLE-SOURCE-BUCKET--zone-id--x-s3"
        }
    }
}
```

Note

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see Why can't I generate an Amazon S3 Inventory Report? .

Configuring inventory by using the S3 console

Use these instructions to configure inventory by using the S3 console.

> **Note**
>
> It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.

   > **Note**
   >
   > Configuring S3 Inventory for directory buckets is not supported in the Amazon Simple Storage Service console. To configure S3 Inventory for directory buckets, use the Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

3. In the buckets list, choose the name of the bucket that you want to configure Amazon S3 Inventory for.
4. Choose the **Management** tab.
5. Under **Inventory configurations**, choose **Create inventory configuration**.
6. For **Inventory configuration name**, enter a name.
7. For **Inventory scope**, do the following:
   - Enter an optional prefix. Don't include the bucket name in the prefix.
   - Choose which object versions to include, either **Current versions only** or **Include all versions**.
8. Under **Report details**, choose the location of the AWS account that you want to save the reports to: **This account** or **A different account**.
9. Under **Destination**, choose the destination bucket where you want the inventory reports to be saved.

   The destination bucket must be in the same AWS Region as the bucket for which you are setting up the inventory. The destination bucket can be in a different AWS account. When

specifying the destination bucket, you can also include an optional prefix to group your inventory reports together.

Under the **Destination** bucket field, you see the **Destination bucket permission** statement that is added to the destination bucket policy to allow Amazon S3 to place data in that bucket. For more information, see Creating a destination bucket policy.

10. Under **Frequency**, choose how often the report will be generated, **Daily** or **Weekly**.
11. For **Output format**, choose one of the following formats for the report:
    - **CSV** – If you plan to use this inventory report with S3 Batch Operations or if you want to analyze this report in another tool, such as Microsoft Excel, choose **CSV**.
    - **Apache ORC**
    - **Apache Parquet**
12. Under **Status**, choose **Enable** or **Disable**.
13. To configure server-side encryption, under **Inventory report encryption**, follow these steps:
    a. Under **Server-side encryption**, choose either **Do not specify an encryption key** or **Specify an encryption key** to encrypt data.
       - To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

         Note

         If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must choose **Specify an encryption key**. Otherwise, copying objects to the destination will fail.

       - To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.

    b. If you chose **Specify an encryption key**, under **Encryption type**, you must choose either **Amazon S3 managed key (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

       SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your

key. For more information about SSE-S3, see Using server-side encryption with Amazon S3 managed keys (SSE-S3). For more information about SSE-KMS, see Using server-side encryption with AWS KMS keys (SSE-KMS).

> **Note**
>
> To encrypt the inventory list file with SSE-KMS, you must grant Amazon S3 permission to use the customer managed key. For instructions, see Grant Amazon S3 Permission to Encrypt Using Your KMS Keys.

c. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.

> **Note**
>
> If the destination bucket that stores the inventory list file is owned by a different AWS account, make sure that you use a fully qualified KMS key ARN to specify your KMS key.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose a symmetric encryption KMS key from the list of available keys. Make sure the KMS key is in the same Region as your bucket.

  > **Note**
  >
  > Both the AWS managed key (`aws/s3`) and your customer managed keys appear in the list. However, the AWS managed key (`aws/s3`) is not supported for SSE-KMS encryption with S3 Inventory.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

14. For **Additional metadata fields**, select one or more of the following to add to the inventory report:

- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Multipart upload** – Specifies that the object was uploaded as a multipart upload. For more information, see Uploading and copying objects using multipart upload in Amazon S3.
- **Replication status** – The replication status of the object. For more information, see Getting replication status information.
- **Encryption status** – The server-side encryption type that's used to encrypt the object. For more information, see Protecting data with server-side encryption.
- **Bucket Key status** – Indicates whether a bucket-level key generated by AWS KMS applies to the object. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information about this field, see Working with the Object ACL field. For more information about ACLs, see Access control list (ACL) overview.
- **Object owner** – The owner of the object.
- **Storage class** – The storage class that's used for storing the object.
- **Intelligent-Tiering: Access tier** – Indicates the access tier (frequent or infrequent) of the object if it was stored in the S3 Intelligent-Tiering storage class. For more information, see Storage class for automatically optimizing data with changing or unknown access patterns.
- You can add the optional **S3 Intelligent-Tiering reference date** field to your inventory report. For objects in the S3 Intelligent-Tiering storage class, this field reports the date that S3 Intelligent-Tiering uses to determine tier-transition eligibility. This date reflects when the object was last considered active for tiering. To include this field, select **S3 Intelligent-Tiering reference date** under the additional metadata fields when you create or edit an inventory configuration, or add `IntelligentTieringReferenceDate` to the `OptionalFields` list in a `PutBucketInventoryConfiguration` request. For more information, see Cataloging and analyzing your data with S3 Inventory.
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag might or might not be an MD5 digest of the object data. Whether it is depends on how the object was created and how it

is encrypted. For more information, see Object in the *Amazon Simple Storage Service API Reference*.

- **Checksum algorithm** – Indicates the algorithm that is used to create the checksum for the object. Supported values include CRC64NVME, CRC32, CRC32C, SHA1, SHA256, MD5, XXHASH64, XXHASH3, XXHASH128, and SHA512. For more information, see Using supported checksum algorithms.
- **All Object Lock configurations** – The Object Lock status of the object, including the following settings:
  - **Object Lock: Retention mode** – The level of protection applied to the object, either *Governance* or *Compliance*.
  - **Object Lock: Retain until date** – The date until which the locked object cannot be deleted.
  - **Object Lock: Legal hold status** – The legal hold status of the locked object.
  - **Object Lock: Event hold status** – The event hold status of the object.
  - **Object Lock: Event hold duration** – The variable retention duration that is configured for the object. Selecting this field also adds an **Object Lock: Event hold duration unit** column (DAYS or YEARS) to the report.

  For information about S3 Object Lock, see How S3 Object Lock works.
- **Lifecycle Expiration Date** – The lifecycle expiration timestamp for objects in your Inventory report. This field will only be populated, if the object is to be expired by an applicable lifecycle rule. In other cases, the field will be empty. For more information, see Expiring objects.

For more information about the contents of an inventory report, see Amazon S3 Inventory list.

For more information about restricting access to certain optional metadata fields in an inventory configuration, see Control S3 Inventory report configuration creation.

15. Choose **Create**.

Using the REST API to work with S3 Inventory

The following are the REST operations that you can use to work with Amazon S3 Inventory.

- DeleteBucketInventoryConfiguration

- GetBucketInventoryConfiguration
- ListBucketInventoryConfigurations
- PutBucketInventoryConfiguration

Locating your inventory list

When an inventory list is published, the manifest files are published to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/manifest.json
 destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/
manifest.checksum
 destination-prefix/amzn-s3-demo-source-bucket/config-ID/hive/dt=YYYY-MM-DD-HH-MM/
symlink.txt
```

- *destination-prefix* is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location within the destination bucket.
- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *config-ID* is added to prevent collisions with multiple inventory reports from the same source bucket that are sent to the same destination bucket. The *config-ID* comes from the inventory report configuration, and is the name for the report that is defined during setup.
- *YYYY-MM-DDTHH-MMZ* is the timestamp that consists of the start time and the date when the inventory report generation process begins scanning the bucket; for example, `2016-11-06T21-32Z`.
- `manifest.json` is the manifest file.
- `manifest.checksum` is the MD5 hash of the content of the `manifest.json` file.
- `symlink.txt` is the Apache Hive-compatible manifest file.

The inventory lists are published daily or weekly to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name.csv.gz
...
```

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name-1.csv.gz
```

- *destination-prefix* is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location in the destination bucket.
- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *example-file-name*`.csv.gz` is one of the CSV inventory files. ORC inventory names end with the file name extension `.orc`, and Parquet inventory names end with the file name extension `.parquet`.

Inventory manifest

The manifest files `manifest.json` and `symlink.txt` describe where the inventory files are located. Whenever a new inventory list is delivered, it is accompanied by a new set of manifest files. These files might overwrite each other. In versioning-enabled buckets, Amazon S3 creates new versions of the manifest files.

Each manifest contained in the `manifest.json` file provides metadata and other basic information about an inventory. This information includes the following:

- The source bucket name
- The destination bucket name
- The version of the inventory
- The creation timestamp in the epoch date format that consists of the start time and the date when the inventory report generation process begins scanning the bucket
- The format and schema of the inventory files
- A list of the inventory files that are in the destination bucket

Whenever a `manifest.json` file is written, it is accompanied by a `manifest.checksum` file that is the MD5 hash of the content of the `manifest.json` file.

Example Inventory manifest in a `manifest.json` file

The following examples show an inventory manifest in a `manifest.json` file for CSV, ORC, and Parquet-formatted inventories.

CSV

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted inventory.

```
{
    "sourceBucket": "amzn-s3-demo-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-inventory-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "CSV",
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,
 Size, LastModifiedDate, ETag, StorageClass, IsMultipartUploaded,
 ReplicationStatus, EncryptionStatus, ObjectLockRetainUntilDate,
 ObjectLockMode, ObjectLockLegalHoldStatus, IntelligentTieringAccessTier,
 BucketKeyStatus, ChecksumAlgorithm, ObjectAccessControlList, ObjectOwner,
 IntelligentTieringReferenceDate",
    "files": [
        {
            "key": "Inventory/amzn-s3-demo-source-bucket/2016-11-06T21-32Z/
files/939c6d46-85a9-4ba8-87bd-9db705a579ce.csv.gz",
            "size": 2147483647,
            "MD5checksum": "f11166069f1990abeb9c97ace9cdfabc"
        }
    ]
}
```

ORC

The following is an example of a manifest in a `manifest.json` file for an ORC-formatted inventory.

```
{
    "sourceBucket": "amzn-s3-demo-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "ORC",
```

```
    "fileSchema":
 "struct<bucket:string,key:string,version_id:string,is_latest:boolean,is_delete_marker:boole
    "files": [
        {
            "key": "inventory/amzn-s3-demo-source-bucket/data/
d794c570-95bb-4271-9128-26023c8b4900.orc",
            "size": 56291,
            "MD5checksum": "5925f4e78e1695c2d020b9f6eexample"
        }
    ]
}
```

Parquet

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted inventory.

```
{
    "sourceBucket": "amzn-s3-demo-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "Parquet",
    "fileSchema": "message s3.inventory { required binary bucket (UTF8);
 required binary key (UTF8); optional binary version_id (UTF8); optional boolean
 is_latest; optional boolean is_delete_marker; optional int64 size; optional
 int64 last_modified_date (TIMESTAMP_MILLIS); optional binary e_tag (UTF8);
 optional binary storage_class (UTF8); optional boolean is_multipart_uploaded;
 optional binary replication_status (UTF8); optional binary encryption_status
 (UTF8); optional int64 object_lock_retain_until_date (TIMESTAMP_MILLIS); optional
 binary object_lock_mode (UTF8); optional binary object_lock_legal_hold_status
 (UTF8); optional binary intelligent_tiering_access_tier (UTF8); optional binary
 bucket_key_status (UTF8); optional binary checksum_algorithm (UTF8); optional
 binary object_access_control_list (UTF8); optional binary object_owner (UTF8);
 optional int64 intelligent_tiering_reference_date (TIMESTAMP_MILLIS);}",
    "files": [
        {
           "key": "inventory/amzn-s3-demo-source-bucket/data/
d754c470-85bb-4255-9218-47023c8b4910.parquet",
            "size": 56291,
            "MD5checksum": "5825f2e18e1695c2d030b9f6eexample"
        }
    ]
```

```
}
```

The `symlink.txt` file is an Apache Hive-compatible manifest file that allows Hive to automatically discover inventory files and their associated data files. The Hive-compatible manifest works with the Hive-compatible services Athena and Amazon Redshift Spectrum. It also works with Hive-compatible applications, including Presto, Apache Hive, Apache Spark, and many others.

> **Important**
>
> The `symlink.txt` Apache Hive-compatible manifest file does not currently work with AWS Glue.
>
> Reading the `symlink.txt` file with Apache Hive and Apache Spark is not supported for ORC and Parquet-formatted inventory files.

Setting up Amazon S3 Event Notifications for inventory completion

You can set up an Amazon S3 event notification to receive notice when the manifest checksum file is created, which indicates that an inventory list has been added to the destination bucket. The manifest is an up-to-date list of all the inventory lists at the destination location.

Amazon S3 can publish events to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see Amazon S3 Event Notifications.

The following notification configuration defines that all `manifest.checksum` files newly added to the destination bucket are processed by the AWS Lambda `cloud-function-list-write`.

```
<NotificationConfiguration>
  <QueueConfiguration>
      <Id>1</Id>
      <Filter>
          <S3Key>
              <FilterRule>
                  <Name>prefix</Name>
                  <Value>destination-prefix/source-bucket</Value>
              </FilterRule>
              <FilterRule>
                  <Name>suffix</Name>
                  <Value>checksum</Value>
```

```
                </FilterRule>
            </S3Key>
        </Filter>
        <CloudFunction>arn:aws:lambda:us-west-2:222233334444:cloud-function-list-write</
CloudFunction>
        <Event>s3:ObjectCreated:*</Event>
    </QueueConfiguration>
    </NotificationConfiguration>
```

For more information, see Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

Querying Amazon S3 Inventory with Amazon Athena

You can query Amazon S3 Inventory files with standard SQL queries by using Amazon Athena in all Regions where Athena is available. To check for AWS Region availability, see the AWS Region Table.

Athena can query Amazon S3 Inventory files in Apache optimized row columnar (ORC), Apache Parquet, or comma-separated values (CSV) format. For best query speed and lower costs, use ORC-formatted or Parquet-formatted inventory files. ORC and Parquet are columnar file formats designed for Apache Hadoop. The columnar format lets the reader read, decompress, and process only the columns that are required for the current query. The ORC and Parquet formats for Amazon S3 Inventory are available in all AWS Regions.

To use Athena to query Amazon S3 Inventory files

1. Create an Athena table. For information about creating a table, see Creating Tables in Amazon Athena in the *Amazon Athena User Guide*.
2. Create your query by using one of the following sample query templates, depending on whether you're querying an ORC-formatted, a Parquet-formatted, or a CSV-formatted inventory report.

   - When you're using Athena to query an ORC-formatted inventory report, use the following sample query as a template.

     The following sample query includes all the optional fields in an ORC-formatted inventory report.

     To use this sample query, do the following:

     - Replace *your_table_name* with the name of the Athena table that you created.

- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

  `s3://amzn-s3-demo-bucket/config-ID/hive/`
- Replace the *2022-01-01-00-00* date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see Partitioning data in Athena.

```
CREATE EXTERNAL TABLE your_table_name (
         bucket string,
         key string,
         version_id string,
         is_latest boolean,
         is_delete_marker boolean,
         size bigint,
         last_modified_date timestamp,
         e_tag string,
         storage_class string,
         is_multipart_uploaded boolean,
         replication_status string,
         encryption_status string,
         object_lock_retain_until_date bigint,
         object_lock_mode string,
         object_lock_legal_hold_status string,
         object_lock_event_hold_status string,
         object_lock_event_hold_duration int,
         object_lock_event_hold_duration_unit string,
         intelligent_tiering_access_tier string,
         bucket_key_status string,
         checksum_algorithm string,
         object_access_control_list string,
         object_owner string,
         lifecycle_expiration_date timestamp
) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'
  STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
  OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
```

```
  LOCATION 's3://amzn-s3-demo-bucket/config-ID/hive/'
  TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
  );
```

- When you're using Athena to query a Parquet-formatted inventory report, use the sample query for an ORC-formatted report. However, use the following Parquet SerDe in place of the ORC SerDe in the `ROW FORMAT SERDE` statement.

  ```
  ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
  ```

- When you're using Athena to query a CSV-formatted inventory report, use the following sample query as a template.

  The following sample query includes all the optional fields in an CSV-formatted inventory report.

  To use this sample query, do the following:

  - Replace *`your_table_name`* with the name of the Athena table that you created.
  - Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
  - Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

    `s3://amzn-s3-demo-bucket/config-ID/hive/`

  - Replace the *`2022-01-01-00-00`* date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see Partitioning data in Athena.

  ```
  CREATE EXTERNAL TABLE your_table_name (
           bucket string,
           key string,
           version_id string,
           is_latest boolean,
           is_delete_marker boolean,
  ```

```
         size string,
         last_modified_date string,
         e_tag string,
         storage_class string,
         is_multipart_uploaded boolean,
         replication_status string,
         encryption_status string,
         object_lock_retain_until_date string,
         object_lock_mode string,
         object_lock_legal_hold_status string,
         object_lock_event_hold_status string,
         object_lock_event_hold_duration string,
         object_lock_event_hold_duration_unit string,
         intelligent_tiering_access_tier string,
         bucket_key_status string,
         checksum_algorithm string,
         object_access_control_list string,
         object_owner string,
         lifecycle_expiration_date string
) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.OpenCSVSerde'
  STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
  OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
  LOCATION 's3://amzn-s3-demo-bucket/config-ID/hive/'
  TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
  );
```

3. You can now run various queries on your inventory, as shown in the following examples. Replace each *user input placeholder* with your own information.

```
# Get a list of the latest inventory report dates available.
SELECT DISTINCT dt FROM your_table_name ORDER BY 1 DESC limit 10;

# Get the encryption status for a provided report date.
```

```
SELECT encryption_status, count(*) FROM your_table_name WHERE dt = 'YYYY-MM-DD-HH-
MM' GROUP BY encryption_status;

# Get the encryption status for inventory report dates in the provided range.
SELECT dt, encryption_status, count(*) FROM your_table_name
WHERE dt > 'YYYY-MM-DD-HH-MM' AND dt < 'YYYY-MM-DD-HH-MM' GROUP BY dt,
 encryption_status;
```

When you configure S3 Inventory to add the Object Access Control List (Object ACL) field to an inventory report, the report displays the value for the Object ACL field as a base64-encoded string. To get the decoded value in JSON for the Object ACL field, you can query this field by using Athena. See the following query examples. For more information about the Object ACL field, see Working with the Object ACL field.

```
# Get the S3 keys that have Object ACL grants with public access.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
 '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
       grants_array,
       grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'uri') = 'http://acs.amazonaws.com/groups/global/AllUsers'
```

```
# Get the S3 keys that have Object ACL grantees in addition to the object owner.
WITH grants AS
    (SELECT key,
    from_utf8(from_base64(object_access_control_list)) AS
 object_access_control_list,
         object_owner,
         CAST(json_extract(from_utf8(from_base64(object_access_control_list)),
         '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))) AS grants_array
    FROM your_table_name)
SELECT key,
       grant,
       objectowner
```

```
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE cardinality(grants_array) > 1 AND element_at(grant, 'canonicalId') !=
 object_owner;
```

```
# Get the S3 keys with READ permission that is granted in the Object ACL.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
 '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
       grants_array,
       grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'permission') = 'READ';
```

```
# Get the S3 keys that have Object ACL grants to a specific canonical user ID.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
 '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
       grants_array,
       grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'canonicalId') = 'user-canonical-id';
```

```
# Get the number of grantees on the Object ACL.
SELECT key,
       object_access_control_list,
       json_array_length(json_extract(object_access_control_list,'$.grants')) AS
 grants_count
```

```
FROM your_table_name;
```

For more information about using Athena, see the Amazon Athena User Guide.

Converting empty version ID strings in Amazon S3 Inventory reports to null strings

> **Note**
>
> **The following procedure applies only to Amazon S3 Inventory reports that include all versions, and only if the "all versions" reports are used as manifests for S3 Batch Operations on buckets that have S3 Versioning enabled.** You are not required to convert strings for S3 Inventory reports that specify the current version only.

You can use S3 Inventory reports as manifests for S3 Batch Operations. However, when S3 Versioning is enabled on a bucket, S3 Inventory reports that include all versions mark any null-versioned objects with empty strings in the version ID field. When an Inventory Report includes all object version IDs, Batch Operations recognizes `null` strings as version IDs, but not empty strings.

When an S3 Batch Operations job uses an "all versions" S3 Inventory report as a manifest, it fails all tasks on objects that have an empty string in the version ID field. To convert empty strings in the version ID field of the S3 Inventory report to `null` strings for Batch Operations, use the following procedure.

Update an Amazon S3 Inventory report for use with Batch Operations

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Navigate to your S3 Inventory report. The inventory report is located in the destination bucket that you specified while configuring your inventory report. For more information about locating inventory reports, see Locating your inventory list.
   a. Choose the destination bucket.
   b. Choose the folder. The folder is named after the original source bucket.
   c. Choose the folder named after the inventory configuration.

d. Select the check box next to the folder named **hive**. Choose **Copy S3 URI** to copy the S3 URI for the folder.

3. Open the Amazon Athena console at https://console.aws.amazon.com/athena/.
4. In the query editor, choose **Settings**, then choose **Manage**. On the **Manage settings** page, for **Location of query result**, choose an S3 bucket to store your query results in.
5. In the query editor, create an Athena table to hold the data in the inventory report using the following command. Replace *table_name* with a name of your choosing, and in the LOCATION clause, insert the S3 URI that you copied earlier. Then choose **Run** to run the query.

```
CREATE EXTERNAL TABLE table_name(bucket string, key string,
 version_id string) PARTITIONED BY (dt string)ROW FORMAT SERDE
 'org.apache.hadoop.hive.serde2.OpenCSVSerde'STORED AS INPUTFORMAT
 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat' OUTPUTFORMAT
 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat' LOCATION 'Copied S3 URI';
```

6. To clear the query editor, choose **Clear**. Then load the inventory report into the table using the following command. Replace *table_name* with the one that you chose in the prior step. Then choose **Run** to run the query.

```
MSCK REPAIR TABLE table_name;
```

7. To clear the query editor, choose **Clear**. Run the following SELECT query to retrieve all entries in the original inventory report and replace any empty version IDs with null strings. Replace *table_name* with the one that you chose earlier, and replace *YYYY-MM-DD-HH-MM* in the WHERE clause with the date of the inventory report that you want this tool to run on. Then choose **Run** to run the query.

```
SELECT bucket as Bucket, key as Key, CASE WHEN version_id = '' THEN 'null' ELSE
 version_id END as VersionId FROM table_name WHERE dt = 'YYYY-MM-DD-HH-MM';
```

8. Return to the Amazon S3 console (https://console.aws.amazon.com/s3/), and navigate to the S3 bucket that you chose for **Location of query result** earlier. Inside, there should be a series of folders ending with the date.

   For example, you should see something like **s3://*amzn-s3-demo-bucket*/*query-result-location*/Unsaved/2021/10/07/**. You should see .csv files containing the results of the SELECT query that you ran.

Choose the CSV file with the latest modified date. Download this file to your local machine for the next step.

9. The generated CSV file contains a header row. To use this CSV file as input for an S3 Batch Operations job, you must remove the header row, because Batch Operations doesn't support header rows on CSV manifests.

   To remove the header row, you can run one of the following commands on the file. Replace *`file.csv`* with the name of your CSV file.

   For macOS and Linux machines, run the `tail` command in a Terminal window.

   ```
   tail -n +2 file.csv > tmp.csv && mv tmp.csv file.csv
   ```

   For Windows machines, run the following script in a Windows PowerShell window. Replace *`File-location`* with the path to your file, and *`file.csv`* with the file name.

   ```
   $ins = New-Object System.IO.StreamReader File-location\file.csv
   $outs = New-Object System.IO.StreamWriter File-location\temp.csv
   try {
       $skip = 0
       while ( !$ins.EndOfStream ) {
           $line = $ins.ReadLine();
           if ( $skip -ne 0 ) {
               $outs.WriteLine($line);
           } else {
               $skip = 1
           }
       }
   } finally {
       $outs.Close();
       $ins.Close();
   }
   Move-Item File-location\temp.csv File-location\file.csv -Force
   ```

10. After removing the header row from the CSV file, you are ready to use it as a manifest in an S3 Batch Operations job. Upload the CSV file to an S3 bucket or location of your choosing, and then create a Batch Operations job using the CSV file as the manifest.

    For more information about creating a Batch Operations job, see Creating an S3 Batch Operations job.

Working with the Object ACL field

An Amazon S3 Inventory report contains a list of the objects in the S3 source bucket and metadata for each object. The Object access control list (ACL) field is a metadata field that is available in Amazon S3 Inventory. Specifically, the Object ACL field contains the access control list (ACL) for each object. The ACL for an object defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information, see Access control list (ACL) overview and Amazon S3 Inventory list.

The Object ACL field in Amazon S3 Inventory reports is defined in JSON format. The JSON data includes the following fields:

- `version` – The version of the Object ACL field format in the inventory reports. It's in date format `yyyy-mm-dd`.
- `status` – Possible values are `AVAILABLE` or `UNAVAILABLE` to indicate whether an Object ACL is available for an object. When the status for the Object ACL is `UNAVAILABLE`, the value of the Object Owner field in the inventory report is also `UNAVAILABLE`.
- `grants` – Grantee-permission pairs that list the permission status of each grantee that is granted by the Object ACL. The available values for a grantee are `CanonicalUser` and `Group`. For more information about grantees, see Grantees in access control lists.

  For a grantee with the `Group` type, a grantee-permission pair includes the following attributes:

  - `uri` – A predefined Amazon S3 group.
  - `permission` – The ACL permissions that are granted on the object. For more information, see ACL permissions on an object.
  - `type` – The type `Group`, which denotes that the grantee is group.

  For a grantee with the `CanonicalUser` type, a grantee-permission pair includes the following attributes:

  - `canonicalId` – An obfuscated form of the AWS account ID. The canonical user ID for an AWS account is specific to that account. You can retrieve the canonical user ID. For more information, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.
  - `permission` – The ACL permissions that are granted on the object. For more information, see ACL permissions on an object.
  - `type` – The type `CanonicalUser`, which denotes that the grantee is an AWS account.

The following example shows possible values for the Object ACL field in JSON format:

```
{
    "version": "2022-11-10",
    "status": "AVAILABLE",
    "grants": [{
        "uri": "http://acs.amazonaws.com/groups/global/AllUsers",
        "permission": "READ",
        "type": "Group"
    }, {
        "canonicalId": "example-canonical-id",
        "permission": "FULL_CONTROL",
        "type": "CanonicalUser"
    }]
}
```

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.
For example, suppose that you have the following Object ACL field in JSON format:

```
{
        "version": "2022-11-10",
        "status": "AVAILABLE",
        "grants": [{
            "canonicalId": "example-canonical-user-ID",
            "type": "CanonicalUser",
            "permission": "READ"
        }]
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQUlMQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2FsSW
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see Querying Amazon S3 Inventory with Amazon Athena.

Best practices design patterns: optimizing Amazon S3 performance

Your applications can easily achieve thousands of transactions per second in request performance when uploading and retrieving storage from Amazon S3. Amazon S3 automatically scales to high request rates. For example, your application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per partitioned Amazon S3 prefix. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by using parallelization. For example, if you create 10 prefixes in an Amazon S3 bucket to parallelize reads, you could scale your read performance to 55,000 read requests per second. Similarly, you can scale write operations by writing to multiple prefixes. The scaling, in the case of both read and write operations, happens gradually and is not instantaneous, and actual performance will vary based on your specific workload characteristics, usage patterns, and system configuration. While Amazon S3 is scaling to your new higher request rate, you may see some 503 (Slow Down) errors. These errors will dissipate when the scaling is complete. For more information about creating and using prefixes, see Organizing objects using prefixes.

Some data lake applications on Amazon S3 scan millions or billions of objects for queries that run over petabytes of data. These data lake applications achieve single-instance transfer rates that maximize the network interface use for their Amazon EC2 instance, which can be up to 100 Gb/s on a single instance. These applications then aggregate throughput across multiple instances to get multiple terabits per second.

Other applications are sensitive to latency, such as social media messaging applications. These applications can achieve consistent small object latencies (and first-byte-out latencies for larger objects) of roughly 100–200 milliseconds.

Other AWS services can also help accelerate performance for different application architectures. For example, if you want higher transfer rates over a single HTTP connection or single-digit millisecond latencies, use Amazon CloudFront or Amazon ElastiCache for caching with Amazon S3.

Additionally, if you want fast data transport over long distances between a client and an S3 bucket, use Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration. Transfer Acceleration uses the globally distributed edge locations in CloudFront to accelerate data transport over geographical distances. If your Amazon S3 workload uses server-side encryption with AWS KMS, see AWS KMS Limits in the AWS Key Management Service Developer Guide for information about the request rates supported for your use case.

The following topics describe best practice guidelines and design patterns for optimizing performance for applications that use Amazon S3. Refer to the Performance guidelines for Amazon S3 and Performance design patterns for Amazon S3 for the most current information about performance optimization for Amazon S3.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

- Performance design patterns for Amazon S3

Performance guidelines for Amazon S3

When building applications that upload and retrieve objects from Amazon S3, follow our best practices guidelines to optimize performance. We also offer more detailed Performance design patterns for Amazon S3 .

To obtain the best performance for your application on Amazon S3, we recommend the following guidelines.

Topics

- Measure performance
- Scale storage connections horizontally
- Use byte-range fetches
- Retry requests for latency-sensitive applications
- Combine Amazon S3 (Storage) and Amazon EC2 (compute) in the same AWS Region
- Use Amazon S3 Transfer Acceleration to minimize latency caused by distance
- Use the latest version of the AWS SDKs

Measure performance

When optimizing performance, look at network throughput, CPU, and DRAM requirements. Depending on the mix of demands for these different resources, it might be worth evaluating different Amazon EC2 instance types. For more information about instance types, see Instance Types in the *Amazon EC2 User Guide*.

It's also helpful to look at DNS lookup time, latency, and data transfer speed using HTTP analysis tools when measuring performance.

To understand the performance requirements and optimize the performance of your application, you can also monitor the 503 error responses that you receive. Monitoring certain performance metrics may incur additional expenses. For more information, see Amazon S3 pricing.

Monitor the number of 503 (Slow Down) status error responses

To monitor the number of 503 status error responses that you get, you can use one of the following options:

- Use Amazon CloudWatch request metrics for Amazon S3. The CloudWatch request metrics include a metric for 5xx status responses. For more information about CloudWatch request metrics, see Monitoring metrics with Amazon CloudWatch.
- Use the 503 (Service Unavailable) error count available in the advanced metrics section of Amazon S3 Storage Lens. For more information, see Using S3 Storage Lens metrics to improve performance.
- Use Amazon S3 server access logging. With server access logging, you can filter and review all requests that receive 503 (Internal Error) responses. You can also use Amazon Athena to parse logs. For more information about server access logging, see Logging requests with server access logging.

By monitoring the number of HTTP 503 status error code, you can often gain valuable insights into which prefixes, keys, or buckets are getting the most throttling requests.

Scale storage connections horizontally

Spreading requests across many connections is a common design pattern to horizontally scale performance. When you build high performance applications, think of Amazon S3 as a very large distributed system, not as a single network endpoint like a traditional storage server. You can achieve the best performance by issuing multiple concurrent requests to Amazon S3. Spread

these requests over separate connections to maximize the accessible bandwidth from Amazon S3. Amazon S3 doesn't have any limits for the number of connections made to your bucket.

Use byte-range fetches

Using the Range HTTP header in a GET Object request, you can fetch a byte-range from an object, transferring only the specified portion. You can use concurrent connections to Amazon S3 to fetch different byte ranges from within the same object. This helps you achieve higher aggregate throughput versus a single whole-object request. Fetching smaller ranges of a large object also allows your application to improve retry times when requests are interrupted. For more information, see Downloading objects.

If objects are PUT using a multipart upload, it's a good practice to GET them in the same part sizes (or at least aligned to part boundaries) for best performance. GET requests can directly address individual parts; for example, `GET ?partNumber=N`.

Retry requests for latency-sensitive applications

Aggressive timeouts and retries help drive consistent latency. Given the large scale of Amazon S3, if the first request is slow, a retried request is likely to take a different path and quickly succeed. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

Combine Amazon S3 (Storage) and Amazon EC2 (compute) in the same AWS Region

Although S3 bucket names are globally unique, each bucket is stored in a Region that you select when you create the bucket. To learn more about bucket naming guidelines, see Buckets overview and Bucket naming rules. To optimize performance, we recommend that you access the bucket from Amazon EC2 instances in the same AWS Region when possible. This helps reduce network latency and data transfer costs.

For more information about data transfer costs, see Amazon S3 Pricing.

Use Amazon S3 Transfer Acceleration to minimize latency caused by distance

Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration manages fast, easy, and secure transfers of files over long geographic distances between the client and an S3 bucket.

Transfer Acceleration takes advantage of the globally distributed edge locations in Amazon CloudFront. As the data arrives at an edge location, it is routed to Amazon S3 over an optimized network path. Transfer Acceleration is ideal for transferring gigabytes to terabytes of data regularly across continents. It's also useful for clients that upload to a centralized bucket from all over the world.

You can use the Amazon S3 Transfer Acceleration Speed comparison tool to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Amazon S3 Transfer Acceleration.

Use the latest version of the AWS SDKs

The AWS SDKs provide built-in support for many of the recommended guidelines for optimizing Amazon S3 performance. The SDKs provide a simpler API for taking advantage of Amazon S3 from within an application and are regularly updated to follow the latest best practices. For example, the SDKs include logic to automatically retry requests on HTTP 503 errors and are investing in code to respond and adapt to slow connections.

The SDKs also provide the Transfer Manager, which automates horizontally scaling connections to achieve thousands of requests per second, using byte-range requests where appropriate. It's important to use the latest version of the AWS SDKs to obtain the latest performance optimization features.

You can also optimize performance when you are using HTTP REST API requests. When using the REST API, you should follow the same best practices that are part of the SDKs. Allow for timeouts and retries on slow requests, and multiple connections to allow fetching of object data in parallel. For information about using the REST API, see the Amazon Simple Storage Service API Reference.

Performance design patterns for Amazon S3

When designing applications to upload and retrieve objects from Amazon S3, use our best practices design patterns for achieving the best performance for your application. We also offer Performance guidelines for Amazon S3 for you to consider when planning your application architecture.

To optimize performance, you can use the following design patterns.

Topics

- Using caching for frequently accessed content
- Timeouts and retries for latency-sensitive applications
- Horizontal scaling and request parallelization for high throughput
- Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers
- Optimizing for high-request rate workloads

Using caching for frequently accessed content

Many applications that store data in Amazon S3 serve a "working set" of data that is repeatedly requested by users. If a workload is sending repeated GET requests for a common set of objects, you can use a cache such as Amazon CloudFront or Amazon ElastiCache to optimize performance. Successful cache adoption can result in low latency and high data transfer rates. Applications that use caching also send fewer direct requests to Amazon S3, which can help reduce request costs.

Amazon CloudFront is a fast content delivery network (CDN) that transparently caches data from Amazon S3 in a large set of geographically distributed points of presence (PoPs). When objects might be accessed from multiple Regions, or over the internet, CloudFront allows data to be cached close to the users that are accessing the objects. This can result in high performance delivery of popular Amazon S3 content. For information about CloudFront, see the Amazon CloudFront Developer Guide.

Amazon ElastiCache is a managed, in-memory cache. With ElastiCache, you can provision Amazon EC2 instances that cache objects in memory. This caching results in orders of magnitude reduction in GET latency and substantial increases in download throughput. To use ElastiCache, you modify application logic to both populate the cache with hot objects and check the cache for hot objects before requesting them from Amazon S3. For examples of using ElastiCache to improve Amazon S3 GET performance, see the blog post Turbocharge Amazon S3 with Amazon ElastiCache for Redis.

Timeouts and retries for latency-sensitive applications

There are certain situations where an application receives a response from Amazon S3 indicating that a retry is necessary. Amazon S3 maps bucket and object names to the object data associated with them. If an application generates high request rates (typically sustained rates of over 5,000 requests per second to a small number of objects), it might receive HTTP 503 *slowdown* responses. If these errors occur, each AWS SDK implements automatic retry logic using exponential backoff. If you are not using an AWS SDK, you should implement retry logic when receiving the HTTP 503

error. For information about back-off techniques, see Retry behavior in the *AWS SDKs and Tools Reference Guide*.

Amazon S3 automatically scales in response to sustained new request rates, dynamically optimizing performance. While Amazon S3 is internally optimizing for a new request rate, you will receive HTTP 503 request responses temporarily until the optimization completes. After Amazon S3 internally optimizes performance for the new request rate, all requests are generally served without retries.

For latency-sensitive applications, Amazon S3 advises tracking and aggressively retrying slower operations. When you retry a request, we recommend using a new connection to Amazon S3 and performing a fresh DNS lookup.

When you make large variably sized requests (for example, more than 128 MB), we advise tracking the throughput being achieved and retrying the slowest 5 percent of the requests. When you make smaller requests (for example, less than 512 KB), where median latencies are often in the tens of milliseconds range, a good guideline is to retry a GET or PUT operation after 2 seconds. If additional retries are needed, the best practice is to back off. For example, we recommend issuing one retry after 2 seconds and a second retry after an additional 4 seconds.

If your application makes fixed-size requests to Amazon S3, you should expect more consistent response times for each of these requests. In this case, a simple strategy is to identify the slowest 1 percent of requests and to retry them. Even a single retry is frequently effective at reducing latency.

If you are using AWS Key Management Service (AWS KMS) for server-side encryption, see Quotas in the *AWS Key Management Service Developer Guide* for information about the request rates that are supported for your use case.

Horizontal scaling and request parallelization for high throughput

Amazon S3 is a very large distributed system. To help you take advantage of its scale, we encourage you to horizontally scale parallel requests to the Amazon S3 service endpoints. In addition to distributing the requests within Amazon S3, this type of scaling approach helps distribute the load over multiple paths through the network.

For high-throughput transfers, Amazon S3 advises using applications that use multiple connections to GET or PUT data in parallel. For example, this is supported by Amazon S3 Transfer Manager in the AWS Java SDK, and most of the other AWS SDKs provide similar constructs. For some

applications, you can achieve parallel connections by launching multiple requests concurrently in different application threads, or in different application instances. The best approach to take depends on your application and the structure of the objects that you are accessing.

You can use the AWS SDKs to issue GET and PUT requests directly rather than employing the management of transfers in the AWS SDK. This approach lets you tune your workload more directly, while still benefiting from the SDK's support for retries and its handling of any HTTP 503 responses that might occur. As a general rule, when you download large objects from Amazon S3, we suggest making concurrent requests to maximize network throughput and optimize download performance. You can achieve this by either requesting specific byte ranges of the object or downloading individual parts of a multipart object simultaneously. This parallel download approach helps fully use your network interface card (NIC) capacity. For objects that were uploaded using multipart upload, we recommend downloading them using the same part sizes or aligning requests to the original part boundaries for best performance. This method of concurrent downloading provides higher aggregate throughput compared to single whole-object requests.

Measuring performance is important when you tune the number of requests to issue concurrently. We recommend starting with a single request at a time. Measure the network bandwidth being achieved and the use of other resources that your application uses in processing the data. You can then identify the bottleneck resource (that is, the resource with the highest usage), and hence the number of requests that are likely to be useful. For example, if processing one request at a time leads to a CPU usage of 25 percent, it suggests that up to four concurrent requests can be accommodated. Measurement is essential, and it is worth confirming resource use as the request rate is increased.

If your application issues requests directly to Amazon S3 using the REST API, we recommend using a pool of HTTP connections and re-using each connection for a series of requests. Avoiding per-request connection setup removes the need to perform TCP slow-start and Secure Sockets Layer (SSL) handshakes on each request. For information about using the REST API, see the Amazon Simple Storage Service API Reference.

Finally, it's worth paying attention to DNS and double-checking that requests are being spread over a wide pool of Amazon S3 IP addresses. DNS queries for Amazon S3 cycle through a large list of IP endpoints. But caching resolvers or application code that reuses a single IP address do not benefit from address diversity and the load balancing that follows from it. Network utility tools such as the `netstat` command line tool can show the IP addresses being used for communication with Amazon S3, and we provide guidelines for DNS configurations to use. For more information about these guidelines, see Making requests in the *Amazon S3 API Reference*.

Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers

Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration is effective at minimizing or eliminating the latency caused by geographic distance between globally dispersed clients and a regional application using Amazon S3. Transfer Acceleration uses the globally distributed edge locations in CloudFront for data transport. The AWS edge network has points of presence in more than 50 locations. Today, it is used to distribute content through CloudFront and to provide rapid responses to DNS queries made to Amazon Route 53.

The edge network also helps to accelerate data transfers into and out of Amazon S3. It is ideal for applications that transfer data across or between continents, have a fast internet connection, use large objects, or have a lot of content to upload. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path. In general, the farther away you are from an Amazon S3 Region, the higher the speed improvement you can expect from using Transfer Acceleration.

You can set up Transfer Acceleration on new or existing buckets. You can use a separate Amazon S3 Transfer Acceleration endpoint to use the AWS edge locations. The best way to test whether Transfer Acceleration helps client request performance is to use the Amazon S3 Transfer Acceleration Speed Comparison tool. Network configurations and conditions vary from time to time and from location to location. So you are charged only for transfers where Amazon S3 Transfer Acceleration can potentially improve your upload performance. For information about using Transfer Acceleration with different AWS SDKs, see Enabling and using S3 Transfer Acceleration.

Optimizing for high-request rate workloads

Applications that generate high request rates to Amazon S3 require specific design patterns to achieve optimal performance. When your application consistently generates more than 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix, you should implement strategies to distribute requests and handle scaling behavior.

Amazon S3 automatically scales to accommodate higher request rates, but this scaling happens gradually. During the scaling process, you might receive HTTP 503 (Slow Down) responses. These responses are temporary and indicate that Amazon S3 is optimizing its internal systems for your new request pattern. Once scaling is complete, your requests will be served without throttling.

To optimize performance for high-request rate workloads, consider the following strategies:

- **Distribute requests across multiple prefixes** – Use a randomized or sequential prefix pattern to spread requests across multiple partitions. For example, instead of using sequential object names like `log-2024-01-01.txt`, use randomized prefixes like `a1b2/log-2024-01-01.txt`. This helps Amazon S3 distribute the load more effectively.
- **Implement exponential backoff for 503 errors** – When you receive HTTP 503 responses, implement retry logic with exponential backoff. Start with a short delay and gradually increase the wait time between retries. The AWS SDKs include built-in retry logic that handles this automatically.
- **Monitor request patterns** – Use Amazon CloudWatch metrics to monitor your request rates and error rates. Pay particular attention to 5xx error metrics, which can indicate when your application is approaching or exceeding current scaling limits.
- **Gradually ramp up request rates** – When launching new applications or significantly increasing request rates, gradually increase your traffic over time rather than immediately jumping to peak rates. This allows Amazon S3 to scale proactively and reduces the likelihood of throttling.
- **Use multiple connections** – Distribute your requests across multiple HTTP connections to maximize throughput and reduce the impact of any single connection issues.

For applications that require consistent high performance, consider using Amazon S3 Express One Zone, which is designed for applications that require single-digit millisecond latencies and can support hundreds of thousands of requests per second. For more information, see S3 Express One Zone.

Hosting a static website using Amazon S3

You can use Amazon S3 to host a static website. On a *static* website, individual webpages include static content. They might also contain client-side scripts.

Note

We recommend that you use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.
With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket and Deploying a static website from S3 using the Amplify console in the *AWS Amplify Console User Guide*.

For more information about hosting a static website on Amazon S3, including instructions and step-by-step walkthroughs, see the following topics.

Important

If the bucket that you're using to host your static website has been encrypted using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you must create an Amazon CloudFront distribution to serve your website because SSE-KMS doesn't support anonymous users. When you create your CloudFront distribution, you must use origin access control (OAC) instead of origin access identity (OAI) to secure the origin. OAI doesn't support SSE-KMS, so you must use OAC instead.
For more information about OAC, see Restrict access to an Amazon S3 origin in the *Amazon CloudFront Developer Guide*. For a tutorial that shows how to host a static website using Amazon CloudFront, see the section called “Hosting video streaming”.

Topics

- Website endpoints
- Enabling website hosting

Website endpoints

When you configure your bucket as a static website, the website is available at the AWS Region-specific website endpoint of the bucket. Website endpoints are different from the endpoints where you send REST API requests. For more information about the differences between the endpoints, see Key differences between a website endpoint and a REST API endpoint.

Depending on your Region, your Amazon S3 website endpoint follows one of these two formats.

- **s3-website dash (-) Region** - `http://bucket-name.s3-website-Region.amazonaws.com`
- **s3-website dot (.) Region** - `http://bucket-name.s3-website.Region.amazonaws.com`

These URLs return the default index document that you configure for the website. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website Endpoints.

> **Note**
>
> To augment the security of your Amazon S3 static websites, the Amazon S3 website endpoint domains (for example, *s3-website-us-east-1.amazonaws.com* or *s3-website.ap-south-1.amazonaws.com*) are registered in the Public Suffix List (PSL). For further security, we recommend that you use cookies with a `__Host-` prefix if you ever need to set sensitive cookies in the domain name for your Amazon S3 static websites. This practice will help to defend your domain against cross-site request forgery attempts (CSRF). For more information see the Set-Cookie page in the Mozilla Developer Network.

If you want your website to be public, you must make all your content publicly readable for your customers to be able to access it at the website endpoint. For more information, see Setting permissions for website access.

Important

- Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can do one of the following:
  - (Recommended) Use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.

    With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket and Deploying a static website from S3 using the Amplify console in the *AWS Amplify Console User Guide*.
  - Use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see How do I use CloudFront to serve HTTPS requests for my Amazon S3 bucket? To use HTTPS with a custom domain, see Configuring a static website using a custom domain registered with Route 53.
- Requester Pays buckets do not allow access through a website endpoint. Any request to such a bucket receives a 403 Access Denied response. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.

Topics

- Website endpoint examples
- Adding a DNS CNAME
- Using a custom domain with Route 53
- Key differences between a website endpoint and a REST API endpoint

Website endpoint examples

The following examples show how you can access an Amazon S3 bucket that is configured as a static website.

Example— Requesting an object at the root level

To request a specific object that is stored at the root level in the bucket, use the following URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/object-name
```

For example, the following URL requests the `photo.jpg` object that is stored at the root level in the bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/photo.jpg
```

Example— Requesting an object in a prefix

To request an object that is stored in a folder in your bucket, use this URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/folder-name/object-name
```

The following URL requests the `docs/doc1.html` object in your bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/docs/doc1.html
```

Adding a DNS CNAME

If you have a registered domain, you can add a DNS CNAME entry to point to the Amazon S3 website endpoint. For example, if you registered the domain `www.example-bucket.com`, you could create a bucket `www.example-bucket.com`, and add a DNS CNAME record that points to `www.example-bucket.com.s3-website.Region.amazonaws.com`. All requests to `http://www.example-bucket.com` are routed to `www.example-bucket.com.s3-website.Region.amazonaws.com`.

For more information, see Customizing Amazon S3 URLs with CNAME records.

Using a custom domain with Route 53

Instead of accessing the website using an Amazon S3 website endpoint, you can use your own domain registered with Amazon Route 53 to serve your content—for example, `example.com`. You can use Amazon S3 with Route 53 to host a website at the root domain. For example, if you have the root domain `example.com` and you host your website on Amazon S3, your website visitors can access the site from their browser by entering either `http://www.example.com` or `http://example.com`.

For an example walkthrough, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

Key differences between a website endpoint and a REST API endpoint

An Amazon S3 website endpoint is optimized for access from a web browser. The following table summarizes the key differences between a REST API endpoint and a website endpoint.

Key difference	REST API endpoint	Website endpoint
Access control	Supports both public and private content	Supports only publicly readable content
Error message handling	Returns an XML-formatted error response	Returns an HTML document
Redirection support	Not applicable	Supports both object-level and bucket-level redirects
Requests supported	Supports all bucket and object operations	Supports only `GET` and `HEAD` requests on objects
Responses to `GET` and `HEAD` requests at the root of a bucket	Returns a list of the object keys in the bucket	Returns the index document that is specified in the website configuration

Key difference	REST API endpoint	Website endpoint
Secure Sockets Layer (SSL) support	Supports SSL connections	Does not support SSL connections

For a complete list of Amazon S3 endpoints, see Amazon S3 endpoints and quotas in the *AWS General Reference*.

Enabling website hosting

When you configure a bucket as a static website, you must enable static website hosting, configure an index document, and set permissions.

You can enable static website hosting using the Amazon S3 console, REST API, the AWS SDKs, the AWS CLI, or CloudFormation.

To configure your website with a custom domain, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

Using the S3 console

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for

website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

    For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.

11. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

    The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Using the REST API

For more information about sending REST requests directly to enable static website hosting, see the following sections in the Amazon Simple Storage Service API Reference:

- PUT Bucket website
- GET Bucket website
- DELETE Bucket website

Using the AWS SDKs

To host a static website on Amazon S3, you configure an Amazon S3 bucket for website hosting and then upload your website content to the bucket. You can also use the AWS SDKs to create, update, and delete the website configuration programmatically. The SDKs provide wrapper classes around the Amazon S3 REST API. If your application requires it, you can send REST API requests directly from your application.

.NET

The following example shows how to use the AWS SDK for .NET to manage website configuration for a bucket. To add a website configuration to a bucket, you provide a bucket name and a website configuration. The website configuration must include an index document and can contain an optional error document. These documents must be stored in the bucket. For more information, see PUT Bucket website. For more information about the Amazon S3 website feature, see Hosting a static website using Amazon S3.

The following C# code example adds a website configuration to the specified bucket. The configuration specifies both the index document and the error document names. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class WebsiteConfigTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string indexDocumentSuffix = "*** index object key ***"; //
 For example, index.html.
        private const string errorDocument = "*** error object key ***"; // For
 example, error.html.
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;
```

```
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            AddWebsiteConfigurationAsync(bucketName, indexDocumentSuffix,
errorDocument).Wait();
        }

        static async Task AddWebsiteConfigurationAsync(string bucketName,
                                               string indexDocumentSuffix,
                                               string errorDocument)
        {
            try
            {
                // 1. Put the website configuration.
                PutBucketWebsiteRequest putRequest = new PutBucketWebsiteRequest()
                {
                    BucketName = bucketName,
                    WebsiteConfiguration = new WebsiteConfiguration()
                    {
                        IndexDocumentSuffix = indexDocumentSuffix,
                        ErrorDocument = errorDocument
                    }
                };
                PutBucketWebsiteResponse response = await
client.PutBucketWebsiteAsync(putRequest);

                // 2. Get the website configuration.
                GetBucketWebsiteRequest getRequest = new GetBucketWebsiteRequest()
                {
                    BucketName = bucketName
                };
                GetBucketWebsiteResponse getResponse = await
client.GetBucketWebsiteAsync(getRequest);
                Console.WriteLine("Index document: {0}",
getResponse.WebsiteConfiguration.IndexDocumentSuffix);
                Console.WriteLine("Error document: {0}",
getResponse.WebsiteConfiguration.ErrorDocument);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
            catch (Exception e)
```

```
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

PHP

The following PHP example adds a website configuration to the specified bucket. The `create_website_config` method explicitly provides the index document and error document names. The example also retrieves the website configuration and prints the response. For more information about the Amazon S3 website feature, see Hosting a static website using Amazon S3.

For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Add the website configuration.
$s3->putBucketWebsite([
    'Bucket'                => $bucket,
    'WebsiteConfiguration'  => [
        'IndexDocument' => ['Suffix' => 'index.html'],
        'ErrorDocument' => ['Key' => 'error.html']
    ]
]);

// Retrieve the website configuration.
$result = $s3->getBucketWebsite([
    'Bucket' => $bucket
]);
```

```
echo $result->getPath('IndexDocument/Suffix');

// Delete the website configuration.
$s3->deleteBucketWebsite([
    'Bucket' => $bucket
]);
```

Using the AWS CLI

For more information about using the AWS CLI to configure an S3 bucket as a static website, see website in the *AWS CLI Command Reference*.

Next, you must configure your index document and set permissions. For information, see Configuring an index document and Setting permissions for website access.

You can also optionally configure an error document, web traffic logging, or a redirect.

Configuring an index document

When you enable website hosting, you must also configure and upload an index document. An *index document* is a webpage that Amazon S3 returns when a request is made to the root of a website or any subfolder. For example, if a user enters `http://www.example.com` in the browser, the user is not requesting any specific page. In that case, Amazon S3 serves up the index document, which is sometimes referred to as the *default page*.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for your bucket, you upload an HTML file with the index document name to your bucket.

The trailing slash at the root-level URL is optional. For example, if you configure your website with `index.html` as the index document, either of the following URLs returns `index.html`.

```
http://example-bucket.s3-website.Region.amazonaws.com/
http://example-bucket.s3-website.Region.amazonaws.com
```

For more information about Amazon S3 website endpoints, see Website endpoints.

Index document and folders

In Amazon S3, a bucket is a flat container of objects. It does not provide any hierarchical organization as the file system on your computer does. However, you can create a logical hierarchy by using object key names that imply a folder structure.

For example, consider a bucket with three objects that have the following key names. Although these are stored with no physical hierarchical organization, you can infer the following logical folder structure from the key names:

- `sample1.jpg` — Object is at the root of the bucket.
- `photos/2006/Jan/sample2.jpg` — Object is in the `photos/2006/Jan` subfolder.
- `photos/2006/Feb/sample3.jpg` — Object is in the `photos/2006/Feb` subfolder.

In the Amazon S3 console, you can also create a folder in a bucket. For example, you can create a folder named `photos`. You can upload objects to the bucket or to the `photos` folder within the bucket. If you add the object `sample.jpg` to the bucket, the key name is `sample.jpg`. If you upload the object to the `photos` folder, the object key name is `photos/sample.jpg`.

If you create a folder structure in your bucket, you must have an index document at each level. In each folder, the index document must have the same name, for example, `index.html`. When a user specifies a URL that resembles a folder lookup, the presence or absence of a trailing slash determines the behavior of the website. For example, the following URL, with a trailing slash, returns the `photos/index.html` index document.

```
http://bucket-name.s3-website.Region.amazonaws.com/photos/
```

However, if you exclude the trailing slash from the preceding URL, Amazon S3 first looks for an object `photos` in the bucket. If the `photos` object is not found, it searches for an index document, `photos/index.html`. If that document is found, Amazon S3 returns a `302 Found` message and points to the `photos/` key. For subsequent requests to `photos/`, Amazon S3 returns `photos/index.html`. If the index document is not found, Amazon S3 returns an error.

Configure an index document

To configure an index document using the S3 console, use the following procedure. You can also configure an index document using the REST API, the AWS SDKs, the AWS CLI, or CloudFormation.

> **Note**
>
> In a versioning-enabled bucket, you may upload multiple copies of the `index.html` but only the newest version will be resolved to. For more information about using S3 Versioning see, Retaining multiple versions of objects with S3 Versioning.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.

6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

   After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

8. (Optional) Upload other website content to your bucket.

Next, you must set permissions for website access. For information, see Setting permissions for website access.

You can also optionally configure an error document, web traffic logging, or a redirect.

Configuring a custom error document

After you configure your bucket as a static website, when an error occurs, Amazon S3 returns an HTML error document. You can optionally configure your bucket with a custom error document so that Amazon S3 returns that document when an error occurs.

> **Note**
>
> Some browsers display their own error message when an error occurs, ignoring the error document that Amazon S3 returns. For example, when an HTTP 404 Not Found error occurs, Google Chrome might ignore the error document that Amazon S3 returns and display its own error.

Topics

- Amazon S3 HTTP response codes
- Configuring a custom error document

Amazon S3 HTTP response codes

The following table lists the subset of HTTP response codes that Amazon S3 returns when an error occurs.

HTTP error code	Description
301 Moved Permanently	When a user sends a request directly to the Amazon S3 website endpoint (`http://s3-website.` *Region*`.amazonaws.com/`), Amazon S3 returns a **301 Moved Permanently** response and redirects those requests to `https://aws.amazon.com/s3/`.
302 Found	When Amazon S3 receives a request for a key `x`, `http://`*bucket-name*`.s3-website.` *Region*`.amazonaws.com/x`, without a trailing slash, it first looks for the object with the key name `x`. If the object is not found, Amazon S3 determines that the request is for subfolder `x` and redirects the request by adding a slash at the end, and returns **302 Found**.
304 Not Modified	Amazon S3 uses request headers `If-Modified-Since`, `If-Unmodified-Since`, `If-Match` and/or `If-None-Match` to determine whether the requested object is same as the cached copy held by the client. If the object is the same, the website endpoint returns a **304 Not Modified** response.
400 Malformed Request	The website endpoint responds with a **400 Malformed Request** when a user attempts to access a bucket through the incorrect regional endpoint.
403 Forbidden	The website endpoint responds with a **403 Forbidden** when a user request translates to an object that is not publicly readable. The object owner must make the object publicly readable using a bucket policy or an ACL.
404 Not Found	The website endpoint responds with **404 Not Found** for the following reasons: •

HTTP error code	Description
	Amazon S3 determines that the URL of the website refers to an object key that does not exist. • Amazon S3 infers that the request is for an index document that does not exist. • A bucket specified in the URL does not exist. • A bucket specified in the URL exists, but isn't configured as a website. You can create a custom document that is returned for **404 Not Found**. Make sure that the document is uploaded to the bucket configured as a website, and that the website hosting configuration is set to use the document. For information on how Amazon S3 interprets the URL as a request for an object or an index document, see Configuring an index document.
500 Service Error	The website endpoint responds with a **500 Service Error** when an internal server error occurs.
503 Service Unavailable	The website endpoint responds with a **503 Service Unavailable** when Amazon S3 determines that you need to reduce your request rate.

For each of these errors, Amazon S3 returns a predefined HTML message. The following is an example HTML message that is returned for a **403 Forbidden** response.

Configuring a custom error document

When you configure your bucket as a static website, you can provide a custom error document that contains a user-friendly error message and additional help. Amazon S3 returns your custom error document for only the HTTP 4XX class of error codes.

To configure a custom error document using the S3 console, follow the steps below. You can also configure an error document using the REST API, the AWS SDKs, the AWS CLI, or CloudFormation. For more information, see the following:

- PutBucketWebsite in the *Amazon Simple Storage Service API Reference*
- AWS::S3::Bucket WebsiteConfiguration in the *CloudFormation User Guide*
- put-bucket-website in the *AWS CLI Command Reference*

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error**

document name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.
7. To upload the error document to your bucket, do one of the following:

   - Drag and drop the error document file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

Setting permissions for website access

When you configure a bucket as a static website, if you want your website to be public, you can grant public read access. To make your bucket publicly readable, you must disable block public access settings for the bucket and write a bucket policy that grants public read access. If your bucket contains objects that are not owned by the bucket owner, you might also need to add an object access control list (ACL) that grants everyone read access.

If you don't want to disable block public access settings for your bucket but you still want your website to be public, you can create a Amazon CloudFront distribution to serve your static website. For more information, see Speeding up your website with Amazon CloudFront or Use an Amazon CloudFront distribution to serve a static website in the *Amazon Route 53 Developer Guide*.

> **Note**
>
> On the website endpoint, if a user requests an object that doesn't exist, Amazon S3 returns HTTP response code `404 (Not Found)`. If the object exists but you haven't granted

read permission on it, the website endpoint returns HTTP response code `403 (Access Denied)`. The user can use the response code to infer whether a specific object exists. If you don't want this behavior, you should not enable website support for your bucket.

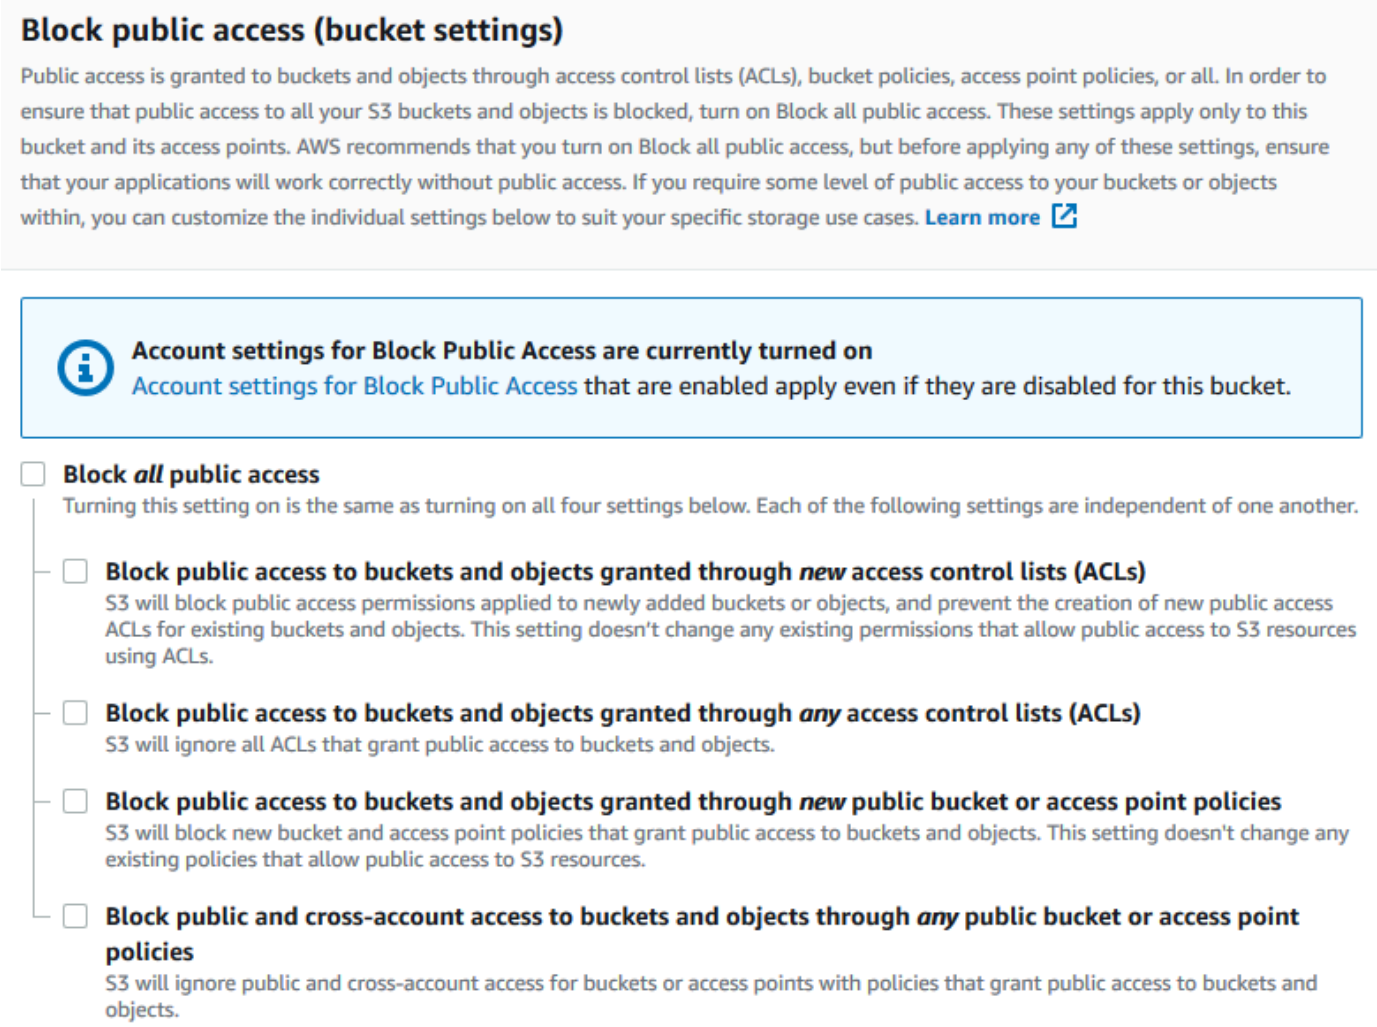
Topics

- Step 1: Edit S3 Block Public Access settings
- Step 2: Add a bucket policy
- Object access control lists

Step 1: Edit S3 Block Public Access settings

If you want to configure an existing bucket as a static website that has public access, you must edit Block Public Access settings for that bucket. You might also have to edit your account-level Block Public Access settings. Amazon S3 applies the most restrictive combination of the bucket-level and account-level block public access settings.

For example, if you allow public access for a bucket but block all public access at the account level, Amazon S3 will continue to block public access to the bucket. In this scenario, you would have to edit your bucket-level and account-level Block Public Access settings. For more information, see Blocking public access to your Amazon S3 storage.



By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.

3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 2: Add a bucket policy

To make the objects in your bucket publicly readable, you must write a bucket policy that grants everyone `s3:GetObject` permission.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

> **Important**
>
> The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *`Bucket-Name`* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

   If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

   If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Object access control lists

You can use a bucket policy to grant public read permission to your objects. However, the bucket policy applies only to objects that are owned by the bucket owner. If your bucket contains objects that aren't owned by the bucket owner, the bucket owner should use the object access control list (ACL) to grant public READ permission on those objects.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To make an object publicly readable using an ACL, grant READ permission to the `AllUsers` group, as shown in the following grant element. Add this grant element to the object ACL. For information about managing ACLs, see Access control list (ACL) overview.

```
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
  </Grantee>
  <Permission>READ</Permission>
</Grant>
```

(Optional) Logging web traffic

You can optionally enable Amazon S3 server access logging for a bucket that is configured as a static website. Server access logging provides detailed records for the requests that are made to your bucket. For more information, see Logging requests with server access logging. If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging. For more information, see Configuring and Using Access Logs in the *Amazon CloudFront Developer Guide*.

To enable server access logging for your static website bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the same Region where you created the bucket that is configured as a static website, create a general purpose bucket for logging, for example `logs.example.com`.
3. Create a folder for the server access logging log files (for example, `logs`).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, `cdn`).

   For more information, see Speeding up your website with Amazon CloudFront.
5. In the **Buckets** list, choose your bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:

   - Browse to the folder and bucket location:

1. Choose **Browse S3**.
2. Choose the bucket name, and then choose the logs folder.
3. Choose **Choose path**.

- Enter the S3 bucket path, for example, **`s3://logs.example.com/logs/`**.

10. Choose **Save changes**.

    In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

(Optional) Configuring a webpage redirect

If your Amazon S3 bucket is configured for static website hosting, you can configure redirects for your bucket or the objects in it. You have the following options for configuring redirects.

Topics

- Redirect requests for your bucket's website endpoint to another bucket or domain
- Configure redirection rules to use advanced conditional redirects
- Redirect requests for an object

Redirect requests for your bucket's website endpoint to another bucket or domain

You can redirect all requests to a website endpoint for a bucket to another bucket or domain. If you redirect all requests, any request made to the website endpoint is redirected to the specified bucket or domain.

For example, if your root domain is `example.com`, and you want to serve requests for both `http://example.com` and `http://www.example.com`, you must create two buckets named `example.com` and `www.example.com`. Then, maintain the content in the `example.com` bucket, and configure the other `www.example.com` bucket to redirect all requests to the `example.com` bucket. For more information, see Configuring a Static Website Using a Custom Domain Name.

To redirect requests for a bucket website endpoint

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Under **Buckets**, choose the name of the bucket that you want to redirect requests from (for example, `www.example.com`).
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Redirect requests for an object**.
6. In the **Host name** box, enter the website endpoint for your bucket or your custom domain.

   For example, if you are redirecting to a root domain address, you would enter **`example.com`**.
7. For **Protocol**, choose the protocol for the redirected requests (**none**,**http**, or **https**).

   If you do not specify a protocol, the default option is **none**.
8. Choose **Save changes**.

Configure redirection rules to use advanced conditional redirects

Using advanced redirection rules, you can route requests conditionally according to specific object key names, prefixes in the request, or response codes. For example, suppose that you delete or rename an object in your bucket. You can add a routing rule that redirects the request to another object. If you want to make a folder unavailable, you can add a routing rule to redirect the request to another webpage. You can also add a routing rule to handle error conditions by routing requests that return the error to another domain when the error is processed.

When enabling static website hosting for your bucket, you can optionally specify advanced redirection rules. Amazon S3 has a limitation of 50 routing rules per website configuration. If you require more than 50 routing rules, you can use object redirect. For more information, see Using the S3 console.

For more information about configuring routing rules using the REST API, see PutBucketWebsite in the *Amazon Simple Storage Service API Reference*.

> **Important**
>
> To create redirection rules in the new Amazon S3 console, you must use JSON. For JSON examples, see Redirection rules examples.

To configure redirection rules for a static website

To add redirection rules for a bucket that already has static website hosting enabled, follow these steps.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of a bucket that you have configured as a static website.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. In **Redirection rules** box, enter your redirection rules in JSON.

   In the S3 console you describe the rules using JSON. For JSON examples, see Redirection rules examples. Amazon S3 has a limitation of 50 routing rules per website configuration.
7. Choose **Save changes**.

Routing rule elements

The following is general syntax for defining the routing rules in a website configuration in JSON and XML To configure redirection rules in the new S3 console, you must use JSON. For JSON examples, see Redirection rules examples.

JSON

```
[
    {
      "Condition": {
        "HttpErrorCodeReturnedEquals": "string",
        "KeyPrefixEquals": "string"
      },
      "Redirect": {
        "HostName": "string",
        "HttpRedirectCode": "string",
        "Protocol": "http"|"https",
        "ReplaceKeyPrefixWith": "string",
        "ReplaceKeyWith": "string"
      }
    }
  ]
```

```
Note: Redirect must each have at least one child element. You can have either
 ReplaceKeyPrefix with or ReplaceKeyWith but not both.
```

XML

```
<RoutingRules> =
    <RoutingRules>
         <RoutingRule>...</RoutingRule>
         [<RoutingRule>...</RoutingRule>
         ...]
    </RoutingRules>

<RoutingRule> =
   <RoutingRule>
      [ <Condition>...</Condition> ]
      <Redirect>...</Redirect>
   </RoutingRule>

<Condition> =
   <Condition>
      [ <KeyPrefixEquals>...</KeyPrefixEquals> ]
      [ <HttpErrorCodeReturnedEquals>...</HttpErrorCodeReturnedEquals> ]
   </Condition>
    Note: <Condition> must have at least one child element.

<Redirect> =
   <Redirect>
      [ <HostName>...</HostName> ]
      [ <Protocol>...</Protocol> ]
      [ <ReplaceKeyPrefixWith>...</ReplaceKeyPrefixWith>  ]
      [ <ReplaceKeyWith>...</ReplaceKeyWith> ]
      [ <HttpRedirectCode>...</HttpRedirectCode> ]
   </Redirect>

Note: <Redirect> must have at least one child element. You can have either
 ReplaceKeyPrefix with or ReplaceKeyWith but not both.
```

The following table describes the elements in the routing rule.

Name	Description
RoutingRules	Container for a collection of RoutingRule elements.
RoutingRule	A rule that identifies a condition and the redirect that is applied when the condition is met. Condition: • A RoutingRules container must contain at least one routing rule.
Condition	Container for describing a condition that must be met for the specified redirect to be applied. If the routing rule does not include a condition, the rule is applied to all requests.
KeyPrefixEquals	The prefix of the object key name from which requests are redirected. KeyPrefixEquals is required if HttpErrorCodeReturnedEquals is not specified. If both KeyPrefixEquals and HttpErrorCodeReturnedEquals are specified, both must be true for the condition to be met.
HttpErrorCodeReturnedEquals	The HTTP error code that must match for the redirect to apply. If an error occurs, and if the error code meets this value, then the specified redirect applies. HttpErrorCodeReturnedEquals is required if KeyPrefixEquals is not specified. If both KeyPrefixEquals and HttpErrorCodeReturnedEquals are specified, both must be true for the condition to be met.
Redirect	

Name	Description
	Container element that provides instructions for redirecting the request. You can redirect requests to another host or another page, or you can specify another protocol to use. A `RoutingRule` must have a `Redirect` element. A `Redirect` element must contain at least one of the following sibling elements: `Protocol`, `HostName`, `ReplaceKeyPrefixWith`, `ReplaceKeyWith`, or `HttpRedirectCode`.
`Protocol`	The protocol, `http` or `https`, to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `Protocol` is not required.
`HostName`	The hostname to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `HostName` is not required.
`ReplaceKeyPrefixWith`	The prefix of the object key name that replaces the value of `KeyPrefixEquals` in the redirect request. If one of its siblings is supplied, `ReplaceKeyPrefixWith` is not required. It can be supplied only if `ReplaceKeyWith` is not supplied.
`ReplaceKeyWith`	The object key to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `ReplaceKeyWith` is not required. It can be supplied only if `ReplaceKeyPrefixWith` is not supplied.

Name	Description
`HttpRedirectCode`	The HTTP redirect code to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `HttpRedirectCode` is not required.

Redirection rules examples

The following examples explain common redirection tasks:

> **Important**
>
> To create redirection rules in the new Amazon S3 console, you must use JSON.

Example 1: Redirect after renaming a key prefix

Suppose that your bucket contains the following objects:

- index.html
- docs/article1.html
- docs/article2.html

You decide to rename the folder from `docs/` to `documents/`. After you make this change, you need to redirect requests for prefix `docs/` to `documents/`. For example, request for `docs/article1.html` will be redirected to `documents/article1.html`.

In this case, you add the following routing rule to the website configuration.

JSON

```
[
    {
        "Condition": {
            "KeyPrefixEquals": "docs/"
        },
```

```
        "Redirect": {
            "ReplaceKeyPrefixWith": "documents/"
        }
    }
]
```

XML

```
  <RoutingRules>
    <RoutingRule>
    <Condition>
      <KeyPrefixEquals>docs/</KeyPrefixEquals>
    </Condition>
    <Redirect>
      <ReplaceKeyPrefixWith>documents/</ReplaceKeyPrefixWith>
    </Redirect>
    </RoutingRule>
  </RoutingRules>
```

Example 2: Redirect requests for a deleted folder to a page

Suppose that you delete the `images/` folder (that is, you delete all objects with the key prefix `images/`). You can add a routing rule that redirects requests for any object with the key prefix `images/` to a page named `folderdeleted.html`.

JSON

```
[
    {
        "Condition": {
            "KeyPrefixEquals": "images/"
        },
        "Redirect": {
            "ReplaceKeyWith": "folderdeleted.html"
        }
    }
]
```

XML

```
  <RoutingRules>
```

```
    <RoutingRule>
    <Condition>
       <KeyPrefixEquals>images/</KeyPrefixEquals>
    </Condition>
    <Redirect>
      <ReplaceKeyWith>folderdeleted.html</ReplaceKeyWith>
    </Redirect>
    </RoutingRule>
  </RoutingRules>
```

Example 3: Redirect to another domain with a specific path

Suppose you want to redirect requests for a specific path to another domain. For example, you want to redirect requests for `/redirect/me` to `https://example.com/new/path`.

When using both `HostName` and `ReplaceKeyWith` together, Amazon S3 constructs the redirect URL by concatenating the hostname and the replacement key with a forward slash between them. Therefore, you should not include a leading slash in the `ReplaceKeyWith` value. Amazon S3 automatically adds the forward slash between the hostname and the replacement key.

JSON

```
[
    {
        "Condition": {
            "KeyPrefixEquals": "redirect/me"
        },
        "Redirect": {
            "HostName": "example.com",
            "ReplaceKeyWith": "new/path"
        }
    }
]
```

XML

```
  <RoutingRules>
    <RoutingRule>
    <Condition>
      <KeyPrefixEquals>redirect/me</KeyPrefixEquals>
    </Condition>
```

```
    <Redirect>
      <HostName>example.com</HostName>
      <ReplaceKeyWith>new/path</ReplaceKeyWith>
    </Redirect>
    </RoutingRule>
  </RoutingRules>
```

This configuration redirects a request for `https://yourbucket.s3-website-region.amazonaws.com/redirect/me` to `https://example.com/new/path`. Note that `ReplaceKeyWith` is set to `new/path` without a leading slash.

Example 4: Redirect for an HTTP error

Suppose that when a requested object is not found, you want to redirect requests to an Amazon Elastic Compute Cloud (Amazon EC2) instance. Add a redirection rule so that when an HTTP status code 404 (Not Found) is returned, the site visitor is redirected to an Amazon EC2 instance that handles the request.

The following example also inserts the object key prefix `report-404/` in the redirect. For example, if you request a page `ExamplePage.html` and it results in an HTTP 404 error, the request is redirected to a page `report-404/ExamplePage.html` on the specified Amazon EC2 instance. If there is no routing rule and the HTTP error 404 occurs, the error document that is specified in the configuration is returned.

JSON

```
[
    {
        "Condition": {
            "HttpErrorCodeReturnedEquals": "404"
        },
        "Redirect": {

    </RoutingRule>
  </RoutingRules>
```

Redirect requests for an object

You can redirect requests for an object to another object or URL by setting the website redirect location in the metadata of the object. You set the redirect by adding the `x-amz-website-redirect-location` property to the object metadata. On the Amazon S3 console, you set the **Website Redirect Location** in the metadata of the object. If you use the Amazon S3 API, you set `x-amz-website-redirect-location`. The website then interprets the object as a 301 redirect.

To redirect a request to another object, you set the redirect location to the key of the target object. To redirect a request to an external URL, you set the redirect location to the URL that you want. For more information about object metadata, see System-defined object metadata.

When you set a page redirect, you can either keep or delete the source object content. For example, if you have a `page1.html` object in your bucket, you can redirect any requests for this page to another object, `page2.html`. You have two options:

- Keep the content of the `page1.html` object and redirect page requests.
- Delete the content of `page1.html` and upload a zero-byte object named `page1.html` to replace the existing object and redirect page requests.

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you have configured as a static website (for example, `example.com`).
3. Under **Objects**, select your object.
4. Choose **Actions**, and choose **Edit metadata**.

5. Choose **Metadata**.
6. Choose **Add Metadata**.
7. Under **Type**, choose **System Defined**.
8. In **Key**, choose **x-amz-website-redirect-location**.
9. In **Value**, enter the key name of the object that you want to redirect to, for example, `/page2.html`.

   For another object in the same bucket, the `/` prefix in the value is required. You can also set the value to an external URL, for example, `http://www.example.com`.
10. Choose **Edit metadata**.

Using the REST API

The following Amazon S3 API actions support the `x-amz-website-redirect-location` header in the request. Amazon S3 stores the header value in the object metadata as `x-amz-website-redirect-location`.

- PUT Object
- Initiate Multipart Upload
- POST Object
- PUT Object - Copy

A bucket configured for website hosting has both the website endpoint and the REST endpoint. A request for a page that is configured as a 301 redirect has the following possible outcomes, depending on the endpoint of the request:

- **Region-specific website endpoint –** Amazon S3 redirects the page request according to the value of the `x-amz-website-redirect-location` property.
- **REST endpoint –** Amazon S3 doesn't redirect the page request. It returns the requested object.

For more information about the endpoints, see Key differences between a website endpoint and a REST API endpoint.

When setting a page redirect, you can either keep or delete the object content. For example, suppose that you have a `page1.html` object in your bucket.

- To keep the content of `page1.html` and only redirect page requests, you can submit a PUT Object - Copy request to create a new `page1.html` object that uses the existing `page1.html` object as the source. In your request, you set the `x-amz-website-redirect-location` header. When the request is complete, you have the original page with its content unchanged, but Amazon S3 redirects any requests for the page to the redirect location that you specify.
- To delete the content of the `page1.html` object and redirect requests for the page, you can send a PUT Object request to upload a zero-byte object that has the same object key: `page1.html`. In the PUT request, you set `x-amz-website-redirect-location` for `page1.html` to the new object. When the request is complete, `page1.html` has no content, and requests are redirected to the location that is specified by `x-amz-website-redirect-location`.

When you retrieve the object using the GET Object action, along with other object metadata, Amazon S3 returns the `x-amz-website-redirect-location` header in the response.

Using cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section provides an overview of CORS. The subtopics describe how you can enable CORS using the Amazon S3 console, or programmatically by using the Amazon S3 REST API and the AWS SDKs.

Cross-origin resource sharing: Use-case scenarios

The following are example scenarios for using CORS.

Scenario 1

Suppose that you are hosting a website in an Amazon S3 bucket named `website` as described in Hosting a static website using Amazon S3. Your users load the website endpoint:

```
http://website.s3-website.us-east-1.amazonaws.com
```

Now you want to use JavaScript on the webpages that are stored in this bucket to be able to make authenticated GET and PUT requests against the same bucket by using the Amazon S3

API endpoint for the bucket, `website.s3.us-east-1.amazonaws.com`. A browser would normally block JavaScript from allowing those requests, but with CORS you can configure your bucket to explicitly enable cross-origin requests from `website.s3-website.us-east-1.amazonaws.com`.

Scenario 2

Suppose that you want to host a web font from your S3 bucket. Again, browsers require a CORS check (also called a preflight check) for loading web fonts. You would configure the bucket that is hosting the web font to allow any origin to make these requests.

How does Amazon S3 evaluate the CORS configuration on a bucket?

When Amazon S3 receives a preflight request from a browser, it evaluates the CORS configuration for the bucket and uses the first `CORSRule` rule that matches the incoming browser request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration.
- The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration.
- The headers listed in the `Access-Control-Request-Headers` header in a pre-flight request must match the headers in the `AllowedHeaders` element in your CORS configuration.

> **Note**
>
> The ACLs and policies continue to apply when you enable CORS on your bucket.

How Object Lambda Access Point supports CORS

When S3 Object Lambda receives a request from a browser or the request includes an `Origin` header, S3 Object Lambda always adds an `"AllowedOrigins":"*"` header field.

For more information about using CORS, see the following topics.

Topics

- Elements of a CORS configuration
- Configuring cross-origin resource sharing (CORS)
- Testing CORS
- Troubleshooting CORS

Elements of a CORS configuration

To configure your bucket to allow cross-origin requests, you create a CORS configuration. The CORS configuration is a document with elements that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. You can add up to 100 rules to the configuration. You can add the CORS configuration as the `cors` subresource to the bucket.

If you are configuring CORS in the S3 console, you must use JSON to create a CORS configuration. The new S3 console only supports JSON CORS configurations.

For more information about the CORS configuration and the elements in it, see the topics below. For instructions on how to add a CORS configuration, see Configuring cross-origin resource sharing (CORS).

> **Important**
>
> In the S3 console, the CORS configuration must be JSON.

Topics

- AllowedMethods element
- AllowedOrigins element
- AllowedHeaders element
- ExposeHeaders element
- MaxAgeSeconds element
- Examples of CORS configurations

`AllowedMethods` element

In the CORS configuration, you can specify the following values for the `AllowedMethods` element.

- GET
- PUT
- POST
- DELETE
- HEAD

`AllowedOrigins` element

In the `AllowedOrigins` element, you specify the origins that you want to allow cross-domain requests from, for example, `http://www.example.com`. The origin string can contain only one `*` wildcard character, such as `http://*.example.com`. You can optionally specify `*` as the origin to enable all the origins to send cross-origin requests. You can also specify `https` to enable only secure origins.

`AllowedHeaders` element

The `AllowedHeaders` element specifies which headers are allowed in a preflight request through the `Access-Control-Request-Headers` header. Each header name in the `Access-Control-Request-Headers` header must match a corresponding entry in the element. Amazon S3 will send only the allowed headers in a response that were requested. For a sample list of headers that can be used in requests to Amazon S3, go to Common Request Headers in the *Amazon Simple Storage Service API Reference* guide.

Each AllowedHeaders string in your configuration can contain at most one * wildcard character. For example, `<AllowedHeader>x-amz-*</AllowedHeader>` will enable all Amazon-specific headers.

`ExposeHeaders` element

Each `ExposeHeader` element identifies a header in the response that you want customers to be able to access from their applications (for example, from a JavaScript `XMLHttpRequest` object). For a list of common Amazon S3 response headers, go to Common Response Headers in the *Amazon Simple Storage Service API Reference* guide.

`MaxAgeSeconds` element

The `MaxAgeSeconds` element specifies the time in seconds that your browser can cache the response for a preflight request as identified by the resource, the HTTP method, and the origin.

Examples of CORS configurations

Instead of accessing a website by using an Amazon S3 website endpoint, you can use your own domain, such as `example1.com` to serve your content. For information about using your own domain, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

The following example CORS configuration has three rules, which are specified as `CORSRule` elements:

- The first rule allows cross-origin PUT, POST, and DELETE requests from the `http://www.example1.com` origin. The rule also allows all headers in a preflight OPTIONS request through the `Access-Control-Request-Headers` header. In response to preflight OPTIONS requests, Amazon S3 returns requested headers.
- The second rule allows the same cross-origin requests as the first rule, but the rule applies to another origin, `http://www.example2.com`.
- The third rule allows cross-origin GET requests from all origins. The `*` wildcard character refers to all origins.

JSON

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example1.com"
        ],
        "ExposeHeaders": []
    },
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
```

```
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example2.com"
        ],
        "ExposeHeaders": []
    },
    {
        "AllowedHeaders": [],
        "AllowedMethods": [
            "GET"
        ],
        "AllowedOrigins": [
            "*"
        ],
        "ExposeHeaders": []
    }
]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedOrigin>http://www.example1.com</AllowedOrigin>

   <AllowedMethod>PUT</AllowedMethod>
   <AllowedMethod>POST</AllowedMethod>
   <AllowedMethod>DELETE</AllowedMethod>

   <AllowedHeader>*</AllowedHeader>
 </CORSRule>
 <CORSRule>
   <AllowedOrigin>http://www.example2.com</AllowedOrigin>

   <AllowedMethod>PUT</AllowedMethod>
   <AllowedMethod>POST</AllowedMethod>
   <AllowedMethod>DELETE</AllowedMethod>

   <AllowedHeader>*</AllowedHeader>
 </CORSRule>
 <CORSRule>
```

```
   <AllowedOrigin>*</AllowedOrigin>
   <AllowedMethod>GET</AllowedMethod>
 </CORSRule>
</CORSConfiguration>
```

The CORS configuration also allows optional configuration parameters, as shown in the following CORS configuration. In this example, the CORS configuration allows cross-origin PUT, POST, and DELETE requests from the `http://www.example.com` origin.

JSON

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example.com"
        ],
        "ExposeHeaders": [
            "x-amz-server-side-encryption",
            "x-amz-request-id",
            "x-amz-id-2"
        ],
        "MaxAgeSeconds": 3000
    }
]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedOrigin>http://www.example.com</AllowedOrigin>
   <AllowedMethod>PUT</AllowedMethod>
   <AllowedMethod>POST</AllowedMethod>
   <AllowedMethod>DELETE</AllowedMethod>
   <AllowedHeader>*</AllowedHeader>
```

```
  <MaxAgeSeconds>3000</MaxAgeSeconds>
  <ExposeHeader>x-amz-server-side-encryption</
ExposeHeader>
  <ExposeHeader>x-amz-request-id</
ExposeHeader>
  <ExposeHeader>x-amz-id-2</ExposeHeader>
 </CORSRule>
</CORSConfiguration>
```

The `CORSRule` element in the preceding configuration includes the following optional elements:

- `MaxAgeSeconds`—Specifies the amount of time in seconds (in this example, 3000) that the browser caches an Amazon S3 response to a preflight OPTIONS request for the specified resource. By caching the response, the browser does not have to send preflight requests to Amazon S3 if the original request will be repeated.
- `ExposeHeaders`—Identifies the response headers (in this example, `x-amz-server-side-encryption`, `x-amz-request-id`, and `x-amz-id-2`) that customers are able to access from their applications (for example, from a JavaScript `XMLHttpRequest` object).

Configuring cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section shows you how to enable CORS using the Amazon S3 console, the Amazon S3 REST API, and the AWS SDKs. To configure your bucket to allow cross-origin requests, you add a CORS configuration to the bucket. A CORS configuration is a document that defines rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) supported for each origin, and other operation-specific information. In the S3 console, the CORS configuration must be a JSON document.

For example CORS configurations in JSON and XML, see Elements of a CORS configuration.

Using the S3 console

This section explains how to use the Amazon S3 console to add a cross-origin resource sharing (CORS) configuration to an S3 bucket.

When you enable CORS on the bucket, the access control lists (ACLs) and other access permission policies continue to apply.

> **Important**
>
> In the S3 console, the CORS configuration must be JSON. For examples CORS configurations in JSON and XML, see Elements of a CORS configuration.

To add a CORS configuration to an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a bucket policy for.
4. Choose **Permissions**.
5. In the **Cross-origin resource sharing (CORS)** section, choose **Edit**.
6. In the **CORS configuration editor** text box, type or copy and paste a new CORS configuration, or edit an existing configuration.

   The CORS configuration is a JSON file. The text that you type in the editor must be valid JSON. For more information, see Elements of a CORS configuration.
7. Choose **Save changes**.

   > **Note**
   >
   > Amazon S3 displays the Amazon Resource Name (ARN) for the bucket next to the **CORS configuration editor** title. For more information about ARNs, see Amazon Resource Names (ARNs) and AWS Service Namespaces in the *Amazon Web Services General Reference*.

Using the AWS SDKs

You can use the AWS SDK to manage cross-origin resource sharing (CORS) for a bucket. For more information about CORS, see Using cross-origin resource sharing (CORS).

The following examples:

- Creates a CORS configuration and sets the configuration on a bucket
- Retrieves the configuration and modifies it by adding a rule
- Adds the modified configuration to the bucket
- Deletes the configuration

Java

Example

Example

For instructions on how to create and test a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```

        List<CORSRule.AllowedMethods> rule2AM = new
ArrayList<CORSRule.AllowedMethods>();
        rule2AM.add(CORSRule.AllowedMethods.GET);
        CORSRule rule2 = new
CORSRule().withId("CORSRule2").withAllowedMethods(rule2AM)
                .withAllowedOrigins(Arrays.asList("*")).withMaxAgeSeconds(3000)
                .withExposedHeaders(Arrays.asList("x-amz-server-side-encryption"));

        List<CORSRule> rules = new ArrayList<CORSRule>();
        rules.add(rule1);
        rules.add(rule2);

        // Add the rules to a new CORS configuration.
        BucketCrossOriginConfiguration configuration = new
BucketCrossOriginConfiguration();
        configuration.setRules(rules);

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(clientRegion)
                    .build();

            // Add the configuration to the bucket.
            s3Client.setBucketCrossOriginConfiguration(bucketName, configuration);

            // Retrieve and display the configuration.
            configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
            printCORSConfiguration(configuration);

            // Add another new rule.
            List<CORSRule.AllowedMethods> rule3AM = new
ArrayList<CORSRule.AllowedMethods>();
            rule3AM.add(CORSRule.AllowedMethods.HEAD);
            CORSRule rule3 = new
CORSRule().withId("CORSRule3").withAllowedMethods(rule3AM)
                    .withAllowedOrigins(Arrays.asList("http://www.example.com"));

            rules = configuration.getRules();
            rules.add(rule3);
```

```
            configuration.setRules(rules);
            s3Client.setBucketCrossOriginConfiguration(bucketName, configuration);

            // Verify that the new rule was added by checking the number of rules in
the
            // configuration.
            configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
            System.out.println("Expected # of rules = 3, found " +
configuration.getRules().size());

            // Delete the configuration.
            s3Client.deleteBucketCrossOriginConfiguration(bucketName);
            System.out.println("Removed CORS configuration.");

            // Retrieve and display the configuration to verify that it was
            // successfully deleted.
            configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
            printCORSConfiguration(configuration);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }

    private static void printCORSConfiguration(BucketCrossOriginConfiguration
configuration) {
        if (configuration == null) {
            System.out.println("Configuration is null.");
        } else {
            System.out.println("Configuration has " +
configuration.getRules().size() + " rules\n");

            for (CORSRule rule : configuration.getRules()) {
                System.out.println("Rule ID: " + rule.getId());
                System.out.println("MaxAgeSeconds: " + rule.getMaxAgeSeconds());
                System.out.println("AllowedMethod: " + rule.getAllowedMethods());
                System.out.println("AllowedOrigins: " + rule.getAllowedOrigins());
                System.out.println("AllowedHeaders: " + rule.getAllowedHeaders());
                System.out.println("ExposeHeader: " + rule.getExposedHeaders());
```

```
                System.out.println();
            }
        }
    }
}
```

.NET

Example

                            AllowedMethods = new List<string> {"GET"},
                            AllowedOrigins = new List<string> {"*"},
                            MaxAgeSeconds = 3000,
                            ExposeHeaders = new List<string> {"x-amz-server-side-
encryption"}
                          }
                        }
                };

                // Add the configuration to the bucket.
                await PutCORSConfigurationAsync(configuration);

                // Retrieve an existing configuration.
                configuration = await RetrieveCORSConfigurationAsync();

                // Add a new rule.
                configuration.Rules.Add(new CORSRule
                {
                    Id = "CORSRule3",
                    AllowedMethods = new List<string> { "HEAD" },
                    AllowedOrigins = new List<string> { "http://www.example.com" }
                });

                // Add the configuration to the bucket.
                await PutCORSConfigurationAsync(configuration);

                // Verify that there are now three rules.
                configuration = await RetrieveCORSConfigurationAsync();
                Console.WriteLine();
                Console.WriteLine("Expected # of rulest=3; found:{0}",
 configuration.Rules.Count);
                Console.WriteLine();
```

```
                Console.WriteLine("Pause before configuration delete. To continue,
click Enter...");
                Console.ReadKey();

                // Delete the configuration.
                await DeleteCORSConfigurationAsync();

                // Retrieve a nonexistent configuration.
                configuration = await RetrieveCORSConfigurationAsync();
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
            }
        }

        static async Task PutCORSConfigurationAsync(CORSConfiguration configuration)
        {

            PutCORSConfigurationRequest request = new PutCORSConfigurationRequest
            {
                BucketName = bucketName,
                Configuration = configuration
            };

            var response = await s3Client.PutCORSConfigurationAsync(request);
        }

        static async Task<CORSConfiguration> RetrieveCORSConfigurationAsync()
        {
            GetCORSConfigurationRequest request = new GetCORSConfigurationRequest
            {
                BucketName = bucketName

            };
            var response = await s3Client.GetCORSConfigurationAsync(request);
            var configuration = response.Configuration;
            PrintCORSRules(configuration);
```

```
            return configuration;
        }

        static async Task DeleteCORSConfigurationAsync()
        {
            DeleteCORSConfigurationRequest request = new
 DeleteCORSConfigurationRequest
            {
                BucketName = bucketName
            };
            await s3Client.DeleteCORSConfigurationAsync(request);
        }

        static void PrintCORSRules(CORSConfiguration configuration)
        {
            Console.WriteLine();

            if (configuration == null)
            {
                Console.WriteLine("\nConfiguration is null");
                return;
            }

            Console.WriteLine("Configuration has {0} rules:",
 configuration.Rules.Count);
            foreach (CORSRule rule in configuration.Rules)
            {
                Console.WriteLine("Rule ID: {0}", rule.Id);
                Console.WriteLine("MaxAgeSeconds: {0}", rule.MaxAgeSeconds);
                Console.WriteLine("AllowedMethod: {0}", string.Join(", ",
 rule.AllowedMethods.ToArray()));
                Console.WriteLine("AllowedOrigins: {0}", string.Join(", ",
 rule.AllowedOrigins.ToArray()));
                Console.WriteLine("AllowedHeaders: {0}", string.Join(", ",
 rule.AllowedHeaders.ToArray()));
                Console.WriteLine("ExposeHeader: {0}", string.Join(", ",
 rule.ExposeHeaders.ToArray()));
            }
        }
    }
}
```

Using the REST API

To set a CORS configuration on your bucket, you can use the AWS Management Console. If your application requires it, you can also send REST requests directly. The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API actions related to the CORS configuration:

- PutBucketCors
- GetBucketCors
- DeleteBucketCors
- OPTIONS object

Testing CORS

To test your CORS configuration, a CORS preflight request can be sent with the `OPTIONS` method so that the server can respond if it is acceptable to send the request. When Amazon S3 receives a preflight request, S3 evaluates the CORS configuration for the bucket and uses the first `CORSRule` rule that matches the incoming request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration.
- The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration.
- The headers listed in the `Access-Control-Request-Headers` header in a preflight request must match the headers in the `AllowedHeaders` element in your CORS configuration.

The following is an example of a CORS configuration. To create a CORS Configuration, see Configuring CORS. For more examples of a CORS configuration, see Elements of a CORS configuration.

For guidance on configuring and troubleshooting CORS rules, see How do I configure CORS in Amazon S3 and confirm the CORS rules using cURL? in the AWS re:Post Knowledge Center.

JSON

```
[
    {
        "AllowedHeaders": [
            "Authorization"
        ],
        "AllowedMethods": [
            "GET",
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example1.com"
        ],
        "ExposeHeaders":  [
             "x-amz-meta-custom-header"
        ]

    }
]
```

To test the CORS configuration, you can send a preflight `OPTIONS` check by using the following CURL command. CURL is a command-line tool that can be used to interact with S3. For more information, see CURL.

```
curl -v -X OPTIONS \
 -H "Origin: http://www.example1.com" \
 -H "Access-Control-Request-Method: PUT" \
 -H "Access-Control-Request-Headers: Authorization" \
 -H "Access-Control-Expose-Headers: x-amz-meta-custom-header"\
    "http://bucket_name.s3.amazonaws.com/object_prefix_name"
```

In the above example, the `curl -v -x OPTIONS` command is used to send a preflight request to S3 to inquire if it is allowed by S3 to send a PUT request on an object from the cross origin `http://www.example1.com`. The headers `Access-Control-Request-Headers` and `Access-Control-Expose-Headers` are optional.

- In response to the `Access-Control-Request-Method` header in the preflight `OPTIONS` request, Amazon S3 returns the list of allowed methods if the requested methods match.
- In response to the `Access-Control-Request-Headers` header in the preflight `OPTIONS` request, Amazon S3 returns the list of allowed headers if the requested headers match.
- In response to the `Access-Control-Expose-Headers` header in the preflight `OPTIONS` request, Amazon S3 returns a list of allowed headers if the requested headers match the allowed headers that can be accessed by scripts running in the browser.

> **Note**
>
> When sending a preflight request, if any of the CORS request headers are not allowed, none of the response CORS headers are returned.

In response to this preflight `OPTIONS` request, you will receive a `200 OK` response. For common error codes received when testing CORS and more information to solve CORS related issues, see Troubleshooting CORS.

```
< HTTP/1.1 200 OK
< Date: Fri, 12 Jul 2024 00:23:51 GMT
< Access-Control-Allow-Origin: http://www.example1.com
< Access-Control-Allow-Methods: GET, PUT, POST, DELETE
< Access-Control-Allow-Headers: Authorization
< Access-Control-Expose-Headers: x-amz-meta-custom-header
< Access-Control-Allow-Credentials: true
< Vary: Origin, Access-Control-Request-Headers, Access-Control-Request-Method
< Server: AmazonS3
< Content-Length: 0
```

Troubleshooting CORS

The following topics can help you troubleshoot some common CORS issues related to S3.

Topics

- 403 Forbidden error: CORS is not enabled for this bucket
- 403 Forbidden error: This CORS request is not allowed
- Headers not found in CORS response

- Considerations of CORS on S3 proxy integrations

403 Forbidden error: CORS is not enabled for this bucket

The following `403 Forbidden` error occurs when a cross-origin request is sent to Amazon S3 but CORS is not configured on your S3 bucket.

Error: HTTP/1.1 403 Forbidden CORS Response: CORS is not enabled for this bucket.

The CORS configuration is a document or policy with rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. See how to configure CORS on S3 by using the Amazon S3 console, AWS SDKs, and REST API. For more information on CORS and examples of a CORS configuration, see Elements of CORS.

403 Forbidden error: This CORS request is not allowed

The following `403 Forbidden` error is received when a CORS rule in your CORS configuration doesn't match the data in your request.

Error: HTTP/1.1 403 Forbidden CORS Response: This CORS request is not allowed.

As a result, this `403 Forbidden` error can occur for multiple reasons:

- Origin is not allowed.
- Methods are not allowed.
- Requested headers are not allowed.

For each request that Amazon S3 receives, you must have a CORS rule in your CORS configuration that matches the data in your request.

Origin is not allowed

The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration. A wildcard character ("`*`") in the `AllowedOrigins` element would match all HTTP methods. For more information on how to update the `AllowedOrigins` element, see Configuring cross-origin resource sharing (CORS).

For example, if only the `http://www.example1.com` domain is included in the `AllowedOrigins` element, then a CORS request sent from the `http://www.example2.com` domain would receive the `403 Forbidden` error.

The following example shows part of a CORS configuration that includes the `http://www.example1.com` domain in the `AllowedOrigins` element.

```
"AllowedOrigins":[
   "http://www.example1.com"
]
```

For a CORS request sent from the `http://www.example2.com` domain to be successful, the `http://www.example2.com` domain should be included in the `AllowedOrigins` element of CORS configuration.

```
"AllowedOrigins":[
   "http://www.example1.com"
   "http://www.example2.com"
]
```

Methods are not allowed

The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration. A wildcard character ("`*`") in `AllowedMethods` would match all HTTP methods. For more information on how to update the `AllowedOrigins` element, see Configuring cross-origin resource sharing (CORS).

In a CORS configuration, you can specify the following methods in the `AllowedMethods` element:

- `GET`
- `PUT`
- `POST`
- `DELETE`
- `HEAD`

The following example shows part of a CORS configuration that includes the `GET` method in the `AllowedMethods` element. Only requests including the `GET` method would succeed.

```
"AllowedMethods":[
   "GET"
]
```

If an HTTP method (for example, PUT) was used in a CORS request or included in a pre-flight CORS request to your bucket but the method isn't present in your CORS configuration, the request would result in a `403 Forbidden` error. To allow this CORS request or CORS pre-flight request, the PUT method must be added to your CORS configuration.

```
"AllowedMethods":[
   "GET"
   "PUT"
]
```

Requested headers are not allowed

The headers listed in the `Access-Control-Request-Headers` header in a pre-flight request must match the headers in the `AllowedHeaders` element in your CORS configuration. For a list of common headers that can be used in requests to Amazon S3, see Common Request Headers. For more information on how to update the `AllowedHeaders` element, see Configuring cross-origin resource sharing (CORS).

The following example shows part of a CORS configuration that includes the `Authorization` header in the `AllowedHeaders` element. Only requests for the `Authorization` header would succeed.

```
"AllowedHeaders":  [
    "Authorization"
]
```

If a header (for example `Content-MD5` was included in a CORS request but the header isn't present in your CORS configuration, the request would result in a `403 Forbidden` error. To allow this CORS request , the `Content-MD5` header must be added to your CORS configuration. If you want to pass both `Authorization` and `Content-MD5` headers in a CORS request to your bucket, confirm that both headers are included in the `AllowedHeaders` element in your CORS configuration.

```
"AllowedHeaders":  [
    "Authorization"
```

```
    "Content-MD5"
]
```

Headers not found in CORS response

The `ExposeHeaders` element in your CORS configuration identifies which response headers that you would like to make accessible to scripts and applications running in browsers, in response to a CORS request.

If your objects stored in your S3 bucket have user-defined metadata (for example, `x-amz-meta-custom-header`) along with the response data, this custom header could contain additional metadata or information that you want to access from your client-side JavaScript code. However, by default, browsers block access to custom headers for security reasons. To allow your client-side JavaScript to access custom headers, you need to include the header in your CORS configuration.

In the example below, the `x-amz-meta-custom-header1` header is included in the `ExposeHeaders` element. The `x-amz-meta-custom-header2` isn't included in the `ExposeHeaders` element and is missing from the CORS configuration. In the response, only the values included in the `ExposeHeaders` element would be returned. If the request included the `x-amz-meta-custom-header2` header in the `Access-Control-Expose-Headers` header, the response would still return a `200 OK`. However, only the permitted header, For example `x-amz-meta-custom-header` would be returned and show in the response.

```
"ExposeHeaders":  [
    "x-amz-meta-custom-header1"
]
```

To ensure all headers appear in the response, add all permitted headers to the `ExposeHeaders` element in your CORS configuration as shown below.

```
"ExposeHeaders":  [
    "x-amz-meta-custom-header1",
    "x-amz-meta-custom-header2"
]
```

Considerations of CORS on S3 proxy integrations

If you are experiencing errors and have already checked the CORS configuration on your S3 bucket, and the cross-origin request is sent to proxies such as AWS CloudFront, try the following:

- Configure the settings to allow the `OPTIONS` method for HTTP requests.
- Configure the proxy to forward the following headers: `Origin`, `Access-Control-Request-Headers`, and `Access-Control-Request-Method`.
- Configure the proxy settings to include the origin header in its cache key. This is important because caching proxies that don't include the origin header in their cache key may serve cached responses that don't include the appropriate CORS headers for different origins.

Some proxies provide pre-defined features for CORS requests. For example, in CloudFront, you can configure a policy that includes the headers

that enable cross-origin resource sharing (CORS) requests when the origin is an Amazon S3 bucket.

This policy has the following settings:

- Headers included in origin requests:

  `Origin`

  `Access-Control-Request-Headers`

  `Access-Control-Request-Method`
- Cookies included in origin requests: None
- Query strings included in origin requests: None

For more information, see Control origin requests with a policy and Use managed origin request policies in the *CloudFront Developer Guide*.

Static website tutorials

The following tutorials or walkthroughs present complete procedures for how to create and configure an Amazon S3 general purpose bucket for static website hosting and hosting on-demand video streaming. The purpose of these tutorials is to provide general guidance. These tutorials are intended for a lab-type environment, and they use example bucket names, user names, and so on. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

- Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53 – You can use Amazon S3 with Amazon CloudFront to host videos for on-demand

viewing in a secure and scalable way. After your video is packaged into the right formats, you can store it on a server or in an S3 general purpose bucket, and then deliver it with CloudFront as viewers request it. In this tutorial, you will learn how to configure your general purpose bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management. CloudFront serves the video from its cache, retrieving it from your general purpose bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see Optimizing caching and availability in the *Amazon CloudFront Developer Guide*.

- Configuring a static website – You can configure a general purpose bucket to function like a website. This tutorial walks you through the steps of hosting a website on Amazon S3 including creating a bucket, enabling static website hosting in the S3 console, creating an index document and creating an error document. For more information, see Hosting a static website using Amazon S3.
- Configuring a static website using a custom domain registered with Route 53 – You can create and configure a general purpose bucket to host a static website and create redirects on S3 for a website with a custom domain name that is registered with Amazon Route 53. You use Route 53 to register domains and to define where you want to route internet traffic for your domain. This tutorial shows how to create Route 53 alias records that routes traffic for your domain and subdomain to your general purpose bucket that contains an HTML file. For more information, see Use your domain for a static website in an Amazon S3 bucket in the *Amazon Route 53 Developer Guide*. After you complete this tutorial, you can optionally use CloudFront to improve the performance of your website. For more information, see Speeding up your website with Amazon CloudFront.
- Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket – We recommend that you use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information, see Deploying a static website from S3 using the Amplify console in the *AWS Amplify Hosting User Guide*.

Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53

You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in a secure and scalable way. Video on demand (VOD) streaming means that your video content is stored on a server and viewers can watch it at any time.

CloudFront is a fast, highly secure, and programmable content delivery network (CDN) service. CloudFront can deliver your content securely over HTTPS from all of the CloudFront edge locations around the globe. For more information about CloudFront, see What is Amazon CloudFront? in the *Amazon CloudFront Developer Guide*.

CloudFront caching reduces the number of requests that your origin server must respond to directly. When a viewer (end user) requests a video that you serve with CloudFront, the request is routed to a nearby edge location closer to where the viewer is located. CloudFront serves the video from its cache, retrieving it from the S3 bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see Optimizing caching and availability in the *Amazon CloudFront Developer Guide*.

Objective

In this tutorial, you configure an S3 bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management.

Topics

- Prerequisites: Register and configure a custom domain with Route 53
- Step 1: Create an S3 bucket
- Step 2: Upload a video to the S3 bucket
- Step 3: Create a CloudFront origin access identity
- Step 4: Create a CloudFront distribution
- Step 5: Access the video through the CloudFront distribution
- Step 6: Configure your CloudFront distribution to use your custom domain name
- Step 7: Access the S3 video through the CloudFront distribution with the custom domain name
- (Optional) Step 8: View data about requests received by your CloudFront distribution
- Step 9: Clean up
- Next steps

Prerequisites: Register and configure a custom domain with Route 53

Before you start this tutorial, you must register and configure a custom domain (for example, **`example.com`**) with Route 53 so that you can configure your CloudFront distribution to use a custom domain name later.

Without a custom domain name, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution domain name/Path to an S3 video
```

For example, **`https://d111111abcdef8.cloudfront.net/sample.mp4`**.

After you configure your CloudFront distribution to use a custom domain name configured with Route 53, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution alternate domain name/Path to an S3 video
```

For example, **`https://www.example.com/sample.mp4`**. A custom domain name is simpler and more intuitive for your viewers to use.

To register a custom domain, see Registering a new domain using Route 53 in the *Amazon Route 53 Developer Guide*.

When you register a domain name with Route 53, Route 53 creates the hosted zone for you, which you will use later in this tutorial. This hosted zone is where you store information about how to route traffic for your domain, for example, to an Amazon EC2 instance or a CloudFront distribution.

There are fees associated with domain registration, your hosted zone, and DNS queries received by your domain. For more information, see Amazon Route 53 Pricing.

> **Note**
>
> When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*.

Step 1: Create an S3 bucket

Create a bucket to store the original video that you plan to stream.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

   > **Note**
   >
   > To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket (for example, **`tutorial-bucket`**).

   For more information about naming buckets in Amazon S3, see General purpose bucket naming rules.
6. For **Region**, choose the AWS Region where you want the bucket to reside.

   If possible, you should pick the Region that is closest to the majority of your viewers. For more information about the bucket Region, see General purpose buckets overview.
7. For **Block Public Access settings for this bucket**, keep the default settings (**Block *all* public access** is enabled).

   Even with **Block *all* public access** enabled, viewers can still access the uploaded video through CloudFront. This feature is a major advantage of using CloudFront to host a video stored in S3.

   We recommend that you keep all settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.
8. For the remaining settings, keep the defaults.

   (Optional) If you want to configure additional bucket settings for your specific use case, see Creating a general purpose bucket.
9. Choose **Create bucket**.

Step 2: Upload a video to the S3 bucket

The following procedure describes how to upload a video file to an S3 bucket by using the console. If you're uploading many large video files to S3, you might want to use Amazon S3 Transfer Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

To upload a file to the bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**.

   For example, you can upload a video file named `sample.mp4`.
7. Choose **Upload**.

Step 3: Create a CloudFront origin access identity

To restrict direct access to the video from your S3 bucket, create a special CloudFront user called an origin access identity (OAI). You will associate the OAI with your distribution later in this tutorial. By using an OAI, you make sure that viewers can't bypass CloudFront and get the video directly from the S3 bucket. Only the CloudFront OAI can access the file in the S3 bucket. For more information, see Restrict access to an Amazon S3 origin in the *Amazon CloudFront Developer Guide*.

> **Important**
>
> If the bucket that you're using to host your static website has been encrypted using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you must use origin access control (OAC) instead of origin access identity (OAI) to secure the origin. OAI doesn't support SSE-KMS, so you must use OAC instead. For more information about OAC, see Restrict access to an Amazon S3 origin in the *Amazon CloudFront Developer Guide*.

To create a CloudFront OAI

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, under the **Security** section, choose **Origin access**.
3. Under the **Identities** tab, choose **Create origin access identity**.
4. Enter a name (for example, **`S3-OAI`**) for the new origin access identity.
5. Choose **Create**.

Step 4: Create a CloudFront distribution

To use CloudFront to serve and distribute the video in your S3 bucket, you must create a CloudFront distribution.

Substeps

- Create a CloudFront distribution
- Review the bucket policy

Create a CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. Choose **Create distribution**.
4. In the **Origin** section, for **Origin domain**, choose the domain name of your S3 origin, which starts with the name of the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
5. For **Origin access**, choose **Legacy access identities**.
6. Under **Origin access identity**, choose the origin access identity that you created in Step 3 (for example, **`S3-OAI`**).
7. Under **Bucket policy**, choose **Yes, update the bucket policy**.
8. In the **Default cache behavior** section, under **Viewer protocol policy**, choose **Redirect HTTP to HTTPS**.

   When you choose this feature, HTTP requests are automatically redirected to HTTPS to secure your website and protect your viewers' data.
9. For the other settings in the **Default cache behaviors** section, keep the default values.

   (Optional) You can control how long your file stays in a CloudFront cache before CloudFront forwards another request to your origin. Reducing the duration allows you to serve dynamic content. Increasing the duration means that your viewers get better performance because your files are more likely to be served directly from the edge cache. A longer duration also reduces the load on your origin. For more information, see Managing how long content stays in the cache (expiration) in the *Amazon CloudFront Developer Guide*.
10. For the other sections, keep the remaining settings set to the defaults.

For more information about the different settings options, see Values That You Specify When You Create or Update a Distribution in the *Amazon CloudFront Developer Guide*.

11. Choose **Create distribution**.
12. On the **General** tab for your CloudFront distribution, under **Details**, the value of the **Last modified** column for your distribution changes from **Deploying** to the timestamp when the distribution was last modified. This process typically takes a few minutes.

Review the bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you used earlier as the origin of your CloudFront distribution (for example, **`tutorial-bucket`**).
4. Choose the **Permissions** tab.
5. In the **Bucket policy** section, confirm that you see a statement similar to the following in the bucket policy text:

```
{
    "Version": "2008-10-17",
    "Id": "PolicyForCloudFrontPrivateContent",
    "Statement": [
        {
            "Sid": "1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access
 Identity EH1HDMB1FH2TC"
            },
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::tutorial-bucket/*"
        }
    ]
}
```

This is the statement that your CloudFront distribution added to your bucket policy when you chose **Yes, update the bucket policy** earlier.

This bucket policy update indicates that you successfully configured the CloudFront distribution to restrict access to the S3 bucket. Because of this restriction, objects in the bucket can be accessed only through your CloudFront distribution.

Step 5: Access the video through the CloudFront distribution

Now, CloudFront can serve the video stored in your S3 bucket. To access your video through CloudFront, you must combine your CloudFront distribution domain name with the path to the video in the S3 bucket.

To create a URL to the S3 video using the CloudFront distribution domain name

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. To get the distribution domain name, do the following:
   a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
   b. After finding the distribution in the list, widen the **Domain name** column to copy the domain name value for your CloudFront distribution.
4. In a new browser tab, paste the distribution domain name that you copied.
5. Return to the previous browser tab, and open the S3 console at https://console.aws.amazon.com/s3/.
6. In the left navigation pane, choose **Buckets**.
7. In the **Buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
8. In the **Objects** list, choose the name of the video that you uploaded in Step 2 (for example, `sample.mp4`).
9. On the object detail page, in the **Object overview** section, copy the value of the **Key**. This value is the path to the uploaded video object in the S3 bucket.
10. Return to the browser tab where you previously pasted the distribution domain name, enter a forward slash (**/**) after the distribution domain name, and then paste the path to the video that you copied earlier (for example, `sample.mp4`).

Now, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution domain name/Path to the S3 video
```

Replace *CloudFront distribution domain name* and *Path to the S3 video* with the appropriate values. An example URL is **https://d111111abcdef8.cloudfront.net/sample.mp4**.

Step 6: Configure your CloudFront distribution to use your custom domain name

To use your own domain name instead of the CloudFront domain name in the URL to access the S3 video, add an alternate domain name to your CloudFront distribution.

Substeps

- Request an SSL certificate
- Add the alternate domain name to your CloudFront distribution
- Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name
- Check whether IPv6 is enabled for your distribution and create another DNS record if needed

Request an SSL certificate

To allow your viewers to use HTTPS and your custom domain name in the URL for your video streaming, use AWS Certificate Manager (ACM) to request a Secure Sockets Layer (SSL) certificate. The SSL certificate establishes an encrypted network connection to the website.

1. Sign in to the AWS Management Console and open the ACM console at https://console.aws.amazon.com/acm/.
2. If the introductory page appears, under **Provision certificates**, choose **Get Started**.
3. On the **Request a certificate** page, choose **Request a public certificate**, and then choose **Request a certificate**.
4. On the **Add domain names** page, enter the fully qualified domain name (FQDN) of the site that you want to secure with an SSL/TLS certificate. You can use an asterisk (*) to request a wildcard certificate to protect several site names in the same domain. For this tutorial, enter

***** and the custom domain name that you configured in Prerequisites. For example, enter **`*.example.com`**, and then choose **Next**.

For more information, see To request an ACM public certificate (console) in the *AWS Certificate Manager User Guide*.

5. On the **Select validation method** page, choose **DNS validation**. Then, choose **Next**.

   If you are able to edit your DNS configuration, we recommend that you use DNS domain validation rather than email validation. DNS validation has multiple benefits over email validation. For more information, see Option 1: DNS validation in the *AWS Certificate Manager User Guide*.
6. (Optional) On the **Add tags** page, tag your certificate with metadata.
7. Choose **Review**.
8. On the **Review** page, verify that the information under **Domain name** and **Validation method** are correct. Then, choose **Confirm and request**.

   The **Validation** page shows that your request is being processed and that the certificate domain is being validated. The certificate awaiting validation is in the **Pending validation** status.
9. On the **Validation** page, choose the down arrow to the left of your custom domain name, and then choose **Create record in Route 53** to validate your domain ownership through DNS.

   Doing this adds a CNAME record provided by AWS Certificate Manager to your DNS configuration.
10. In the **Create record in Route 53** dialog box, choose **Create**.

    The **Validation** page should display a **Success** status notification.
11. Choose **Continue** to view the **Certificates** list page.

    The **Status** for your new certificate changes from **Pending validation** to **Issued** within 30 minutes.

Add the alternate domain name to your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.

3. Choose the ID for the distribution that you created in Step 4.
4. On the **General** tab, go to the **Settings** section, and choose **Edit**.
5. On the **Edit settings** page, for **Alternate domain name (CNAME) - *optional***, choose **Add item** to add the custom domain names that you want to use in the URL for the S3 video served by this CloudFront distribution.

   In this tutorial, for example, if you want to route traffic for a subdomain, such as `www.example.com`, enter the subdomain name (`www`) with the domain name (`example.com`). Specifically, enter **`www.example.com`**.

   > **Note**
   >
   > The alternate domain name (CNAME) that you add must be covered by the SSL certificate that you previously attached to your CloudFront distribution.

6. For **Custom SSL certificate - *optional***, choose the SSL certificate that you requested earlier (for example, **`*.example.com`**).

   > **Note**
   >
   > If you don't see the SSL certificate immediately after you request it, wait 30 minutes, and then refresh the list until the SSL certificate is available for you to select.

7. Keep the remaining settings set to the defaults. Choose **Save changes**.
8. On the **General** tab for the distribution, wait for the value of **Last modified** to change from **Deploying** to the timestamp when the distribution was last modified.

Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).
4. Choose **Create record**, and then use the **Quick create record** method.

5. For **Record name**, keep the value for the record name the same as the alternate domain name of the CloudFront distribution that you added earlier.

   In this tutorial, to route traffic to a subdomain, such as `www.example.com`, enter the subdomain name without the domain name. For example, enter only **`www`** in the text field before your custom domain name.
6. For **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Value**, choose the **Alias** toggle to enable the alias resource.
8. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
9. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in Step 4.

   To find the domain name of your CloudFront distribution, do the following:

   a. In a new browser tab, sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v3/home.
   b. In the left navigation pane, choose **Distributions**.
   c. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
   d. After finding the distribution in the list, widen the **Domain name** column to see the domain name value for your CloudFront distribution.
10. On the **Create record** page in the Route 53 console, for the remaining settings, keep the defaults.
11. Choose **Create records**.

Check whether IPv6 is enabled for your distribution and create another DNS record if needed

If IPv6 is enabled for your distribution, you must create another DNS record.

1. To check whether IPv6 is enabled for your distribution, do the following:

   a. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
   b. In the left navigation pane, choose **Distributions**.
   c. Choose the ID of the CloudFront distribution that you created in Step 4.

d. On the **General** tab, under **Settings**, check whether **IPv6** is set to **Enabled**.

If IPv6 is enabled for your distribution, you must create another DNS record.

2. If IPv6 is enabled for your distribution, do the following to create a DNS record:

a. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.

b. In the left navigation pane, choose **Hosted zones**.

c. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).

d. Choose **Create record**, and then use the **Quick create record** method.

e. For **Record name**, in the text field before your custom domain name, type the same value that you typed when you created the IPv4 DNS record earlier. For example, in this tutorial, to route traffic for the subdomain `www.example.com`, enter only **`www`**.

f. For **Record type**, choose **AAAA - Routes traffic to an IPv6 address and some AWS resources**.

g. For **Value**, choose the **Alias** toggle to enable the alias resource.

h. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.

i. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in Step 4.

j. For the remaining settings, keep the defaults.

k. Choose **Create records**.

Step 7: Access the S3 video through the CloudFront distribution with the custom domain name

To access the S3 video using the custom URL, you must combine your alternate domain name with the path to the video in the S3 bucket.

To create a custom URL to access the S3 video through the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. To get the alternate domain name of your CloudFront distribution, do the following:

a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).

b. After finding the distribution in the list, widen the **Alternate domain names** column to copy the value of the alternate domain name of your CloudFront distribution.

4. In a new browser tab, paste the alternate domain name of the CloudFront distribution.
5. Return to the previous browser tab, and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
6. Find the path to your S3 video, as explained in Step 5.
7. Return to the browser tab where you previously pasted the alternate domain name, enter a forward slash (**/**), and then paste the path to your S3 video (for example, `sample.mp4`).

   Now, your S3 video is publicly accessible and hosted through CloudFront at a custom URL that looks similar to the following:

   ```
   https://CloudFront distribution alternate domain name/Path to the S3 video
   ```

   Replace *`CloudFront distribution alternate domain name`* and *`Path to the S3 video`* with the appropriate values. An example URL is **`https://www.example.com/sample.mp4`**.

(Optional) Step 8: View data about requests received by your CloudFront distribution

To view data about requests received by your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, under **Reports & analytics**, choose the reports from the console, ranging from **Cache statistics**, **Popular Objects**, **Top Referrers**, **Usage**, and **Viewers**.

   You can filter each report dashboard. For more information, see CloudFront Reports in the Console in the *Amazon CloudFront Developer Guide*.
3. To filter data, choose the ID of the CloudFront distribution that you created in Step 4.

Step 9: Clean up

If you hosted an S3 streaming video using CloudFront and Route 53 only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

> **Note**
>
> When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*.

Substeps

- Delete the CloudFront distribution
- Delete the DNS record
- Delete the public hosted zone for your custom domain
- Delete the custom domain name from Route 53
- Delete the original video in the S3 source bucket
- Delete the S3 source bucket

Delete the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. To delete the CloudFront distribution, you must disable it first.

   - If the value of the **Status** column is **Enabled** and the value of **Last modified** is the timestamp when the distribution was last modified, continue to disable the distribution before deleting it.
   - If the value of **Status** is **Enabled** and the value of **Last modified** is **Deploying**, wait until the value of **Status** changes to the timestamp when the distribution was last modified. Then continue to disable the distribution before deleting it.

5. To disable the CloudFront distribution, do the following:

   a. In the **Distributions** list, select the check box next to the ID for the distribution that you want to delete.

   b. To disable the distribution, choose **Disable**, and then choose **Disable** to confirm.

      If you disable a distribution that has an alternate domain name associated with it, CloudFront stops accepting traffic for that domain name (such as `www.example.com`), even if another distribution has an alternate domain name with a wildcard (`*`) that matches the same domain (such as `*.example.com`).

   c. The value of **Status** immediately changes to **Disabled**. Wait until the value of **Last modified** changes from **Deploying** to the timestamp when the distribution was last modified.

      Because CloudFront must propagate this change to all edge locations, it might take a few minutes before the update is complete and the **Delete** option is available for you to delete the distribution.

6. To delete the disabled distribution, do the following:

   a. Choose the check box next to the ID for the distribution that you want to delete.

   b. Choose **Delete**, and then choose **Delete** to confirm.

Delete the DNS record

If you want to delete the public hosted zone for the domain (including the DNS record), see Delete the public hosted zone for your custom domain in the *Amazon Route 53 Developer Guide*. If you only want to delete the DNS record created in Step 6, do the following:

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).
4. In the list of records, select the check box next to the records that you want to delete (the records that you created in Step 6).

> **Note**
>
> You can't delete records that have a **Type** value of **NS** or **SOA**.

5. Choose **Delete records**.
6. To confirm the deletion, choose **Delete**.

   Changes to records take time to propagate to the Route 53 DNS servers. Currently, the only way to verify that your changes have propagated is to use the GetChange API action. Changes usually propagate to all Route 53 name servers within 60 seconds.

Delete the public hosted zone for your custom domain

> **Warning**
>
> If you want to keep your domain registration but stop routing internet traffic to your website or web application, we recommend that you delete records in the hosted zone (as described in the prior section) instead of deleting the hosted zone.
> If you delete a hosted zone, someone else can use the domain and route traffic to their own resources using your domain name.
> In addition, if you delete a hosted zone, you can't undelete it. You must create a new hosted zone and update the name servers for your domain registration, which can take up to 48 hours to take effect.
> If you want to make the domain unavailable on the internet, you can first transfer your DNS service to a free DNS service and then delete the Route 53 hosted zone. This prevents future DNS queries from possibly being misrouted.
>
> 1. If the domain is registered with Route 53, see Adding or changing name servers and glue records for a domain in the *Amazon Route 53 Developer Guide* for information about how to replace Route 53 name servers with name servers for the new DNS service.
> 2. If the domain is registered with another registrar, use the method provided by the registrar to change name servers for the domain.

> **Note**
>
> If you're deleting a hosted zone for a subdomain (`www.example.com`), you don't need to change name servers for the domain (`example.com`).

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that you want to delete.
4. On the **Records** tab for your hosted zone, confirm that the hosted zone that you want to delete contains only an **NS** and an **SOA** record.

   If it contains additional records, delete them first.

   If you created any NS records for subdomains in the hosted zone, delete those records too.
5. On the **DNSSEC signing** tab for your hosted zone, disable DNNSSEC signing if it was enabled. For more information, see Disabling DNSSEC signing in the *Amazon Route 53 Developer Guide*.
6. On the details page of the hosted zone, choose **Delete zone**.
7. To confirm the deletion, enter **`delete`**, and then choose **Delete**.

Delete the custom domain name from Route 53

For most top-level domains (TLDs), you can delete the registration if you no longer want it. If you delete a domain name registration from Route 53 before the registration is scheduled to expire, AWS does not refund the registration fee. For more information, see Deleting a domain name registration in the *Amazon Route 53 Developer Guide*.

> **Important**
>
> If you want to transfer the domain between AWS accounts or transfer the domain to another registrar, don't delete the domain and expect to immediately reregister it. Instead, see the applicable documentation in the *Amazon Route 53 Developer Guide*:
>
> - Transferring a domain to a different AWS account

- Transferring a domain from Amazon Route 53 to another registrar

Delete the original video in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the video to in Step 2 (for example, **`tutorial-bucket`**).
4. On the **Objects** tab, select the check box next to the name of the object that you want to delete (for example, `sample.mp4`).
5. Choose **Delete**.
6. Under **Permanently delete objects?**, enter **`permanently delete`** to confirm that you want to delete this object.
7. Choose **Delete objects**.

Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, select the option button next to the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

Next steps

After you complete this tutorial, you can further explore the following related use cases:

- Transcode S3 videos into streaming formats needed by a particular television or connected device before hosting these videos with a CloudFront distribution.

To use Amazon S3 Batch Operations, AWS Lambda and AWS Elemental MediaConvert to batch-transcode a collection of videos to a variety of output media formats, see Tutorial: Batch-transcoding videos with S3 Batch Operations.

- Host other objects stored in S3, such as images, audio, motion graphics, style sheets, HTML, JavaScript, React apps, and so on, using CloudFront and Route 53.

  For example, see Tutorial: Configuring a static website using a custom domain registered with Route 53 and Speeding up your website with Amazon CloudFront.
- Use Amazon S3 Transfer Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. Transfer Acceleration improves transfer performance by routing traffic through the CloudFront globally distributed edge locations and over the AWS backbone networks. It also uses network protocol optimizations. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

Tutorial: Configuring a static website on Amazon S3

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS CLI and AWS SDKs. For more information, see Default encryption FAQ.

You can configure an Amazon S3 bucket to function like a website. This example walks you through the steps of hosting a website on Amazon S3.

Important

The following tutorial requires disabling Block Public Access. We recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled

and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks. For more information, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

Topics

- Step 1: Create a bucket
- Step 2: Enable static website hosting
- Step 3: Edit Block Public Access settings
- Step 4: Add a bucket policy that makes your bucket content publicly available
- Step 5: Configure an index document
- Step 6: Configure an error document
- Step 7: Test your website endpoint
- Step 8: Clean up

Step 1: Create a bucket

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see Creating a general purpose bucket.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose **Create bucket**.
3. Enter the **Bucket name** (for example, **`example.com`**).
4. Choose the Region where you want to create the bucket.

   Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

5. To accept the default settings and create the bucket, choose **Create**.

Step 2: Enable static website hosting

After you create a bucket, you can enable static website hosting for your bucket. You can create a new bucket or use an existing bucket.

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.
9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.
10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.

11. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

    The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Step 3: Edit Block Public Access settings

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 4: Add a bucket policy that makes your bucket content publicly available

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *`Bucket-Name`* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Step 5: Configure an index document

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

4. In the left navigation pane, choose **General purpose buckets**.

5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

   After enabling static website hosting, proceed to step 6.
7. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.
8. (Optional) Upload other website content to your bucket.

Step 6: Configure an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.
3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.

6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

   - Drag and drop the error document file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

Step 7: Test your website endpoint

After you configure static website hosting for your bucket, you can test your website endpoint.

> **Note**
>
> Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.
> For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

   Your index document opens in a separate browser window.

You now have a website hosted on Amazon S3. This website is available at the Amazon S3 website endpoint. However, you might have a domain, such as `example.com`, that you want to use to serve the content from the website you created. You might also want to use Amazon S3 root domain support to serve requests for both `http://www.example.com` and `http://example.com`. This requires additional steps. For an example, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

Step 8: Clean up

If you created your static website only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available. For more information, see Deleting a general purpose bucket.

Tutorial: Configuring a static website using a custom domain registered with Route 53

Suppose that you want to host a static website on Amazon S3. You've registered a domain with Amazon Route 53 (for example, `example.com`), and you want requests for `http://www.example.com` and `http://example.com` to be served from your Amazon S3 content. You can use this walkthrough to learn how to host a static website and create redirects on Amazon S3 for a website with a custom domain name that is registered with Route 53. You can work with an existing website that you want to host on Amazon S3, or use this walkthrough to start from scratch.

After you complete this walkthrough, you can optionally use Amazon CloudFront to improve the performance of your website. For more information, see Speeding up your website with Amazon CloudFront.

> **Note**
>
> Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For a tutorial about how to host your content securely with CloudFront and Amazon S3, see Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53. For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

Automating static website setup with an CloudFormation template

You can use an CloudFormation template to automate your static website setup. The CloudFormation template sets up the components that you need to host a secure static website so that you can focus more on your website's content and less on configuring components.

The CloudFormation template includes the following components:

- Amazon S3 – Creates an Amazon S3 bucket to host your static website.
- CloudFront – Creates a CloudFront distribution to speed up your static website.
- Lambda@Edge – Uses Lambda@Edge to add security headers to every server response. Security headers are a group of headers in the web server response that tell web browsers to take extra security precautions. For more information, see the blog post Adding HTTP security headers using Lambda@Edge and Amazon CloudFront.

This CloudFormation template is available for you to download and use. For information and instructions, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

Topics

- Before you begin
- Step 1: Register a custom domain with Route 53
- Step 2: Create two buckets
- Step 3: Configure your root domain bucket for website hosting
- Step 4: Configure your subdomain bucket for website redirect
- Step 5: Configure logging for website traffic
- Step 6: Upload index and website content
- Step 7: Upload an error document
- Step 8: Edit S3 Block Public Access settings
- Step 9: Attach a bucket policy
- Step 10: Test your domain endpoint
- Step 11: Add alias records for your domain and subdomain
- Step 12: Test the website
- Speeding up your website with Amazon CloudFront
- Cleaning up your example resources

Before you begin

As you follow the steps in this example, you work with the following services:

Amazon Route 53 – You use Route 53 to register domains and to define where you want to route internet traffic for your domain. The example shows how to create Route 53 alias records that

route traffic for your domain (`example.com`) and subdomain (`www.example.com`) to an Amazon S3 bucket that contains an HTML file.

Amazon S3 – You use Amazon S3 to create buckets, upload a sample website page, configure permissions so that everyone can see the content, and then configure the buckets for website hosting.

Step 1: Register a custom domain with Route 53

If you don't already have a registered domain name, such as `example.com`, register one with Route 53. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*. After you register your domain name, you can create and configure your Amazon S3 buckets for website hosting.

Step 2: Create two buckets

To support requests from both the root domain and subdomain, you create two buckets.

- **Domain bucket** – `example.com`
- **Subdomain bucket** – `www.example.com`

These bucket names must match your domain name exactly. In this example, the domain name is `example.com`. You host your content out of the root domain bucket (`example.com`). You create a redirect request for the subdomain bucket (`www.example.com`). If someone enters `www.example.com` in their browser, they are redirected to `example.com` and see the content that is hosted in the Amazon S3 bucket with that name.

To create your buckets for website hosting

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see Creating a general purpose bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create your root domain bucket:

    a. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

> **Note**
>
> To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

b. In the left navigation pane, choose **General purpose buckets**.

c. Choose **Create bucket**. The **Create bucket** page opens.

d. Enter the **Bucket name** (for example, **`example.com`**).

e. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

f. To accept the default settings and create the bucket, choose **Create**.

3. Create your subdomain bucket:

a. Choose **Create bucket**.

b. Enter the **Bucket name** (for example, **`www.example.com`**).

c. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

d. To accept the default settings and create the bucket, choose **Create**.

In the next step, you configure `example.com` for website hosting.

Step 3: Configure your root domain bucket for website hosting

In this step, you configure your root domain bucket (`example.com`) as a website. This bucket will contain your website content. When you configure a bucket for website hosting, you can access the website using the Website endpoints.

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.
9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.
10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

    For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.
11. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.
12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

After you edit block public access settings and add a bucket policy that allows public read access, you can use the website endpoint to access your website.

In the next step, you configure your subdomain (`www.example.com`) to redirect requests to your domain (`example.com`).

Step 4: Configure your subdomain bucket for website redirect

After you configure your root domain bucket for website hosting, you can configure your subdomain bucket to redirect all requests to the domain. In this example, all requests for `www.example.com` are redirected to `example.com`.

To configure a redirect request

1. On the Amazon S3 console, in the **General purpose buckets** list, choose your subdomain bucket name (`www.example.com` in this example).
2. Choose **Properties**.
3. Under **Static website hosting**, choose **Edit**.
4. Choose **Redirect requests for an object**.
5. In the **Target bucket** box, enter your root domain, for example, **`example.com`**.
6. For **Protocol**, choose **http**.
7. Choose **Save changes**.

Step 5: Configure logging for website traffic

If you want to track the number of visitors accessing your website, you can optionally enable logging for your root domain bucket. For more information, see Logging requests with server access logging. If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging.

To enable server access logging for your root domain bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the same Region where you created the bucket that is configured as a static website, create a bucket for logging, for example `logs.example.com`.
3. Create a folder for the server access logging log files (for example, `logs`).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, `cdn`).

   > **Important**
   >
   > When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

5. In the **Buckets** list, choose your root domain bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:

   - Browse to the folder and bucket location:
     1. Choose **Browse S3**.
     2. Choose the bucket name, and then choose the logs folder.
     3. Choose **Choose path**.
   - Enter the S3 bucket path, for example, `s3://logs.example.com/logs/`.

10. Choose **Save changes**.

    In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

Step 6: Upload index and website content

In this step, you upload your index document and optional website content to your root domain bucket.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

8. (Optional) Upload other website content to your bucket.

Step 7: Upload an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

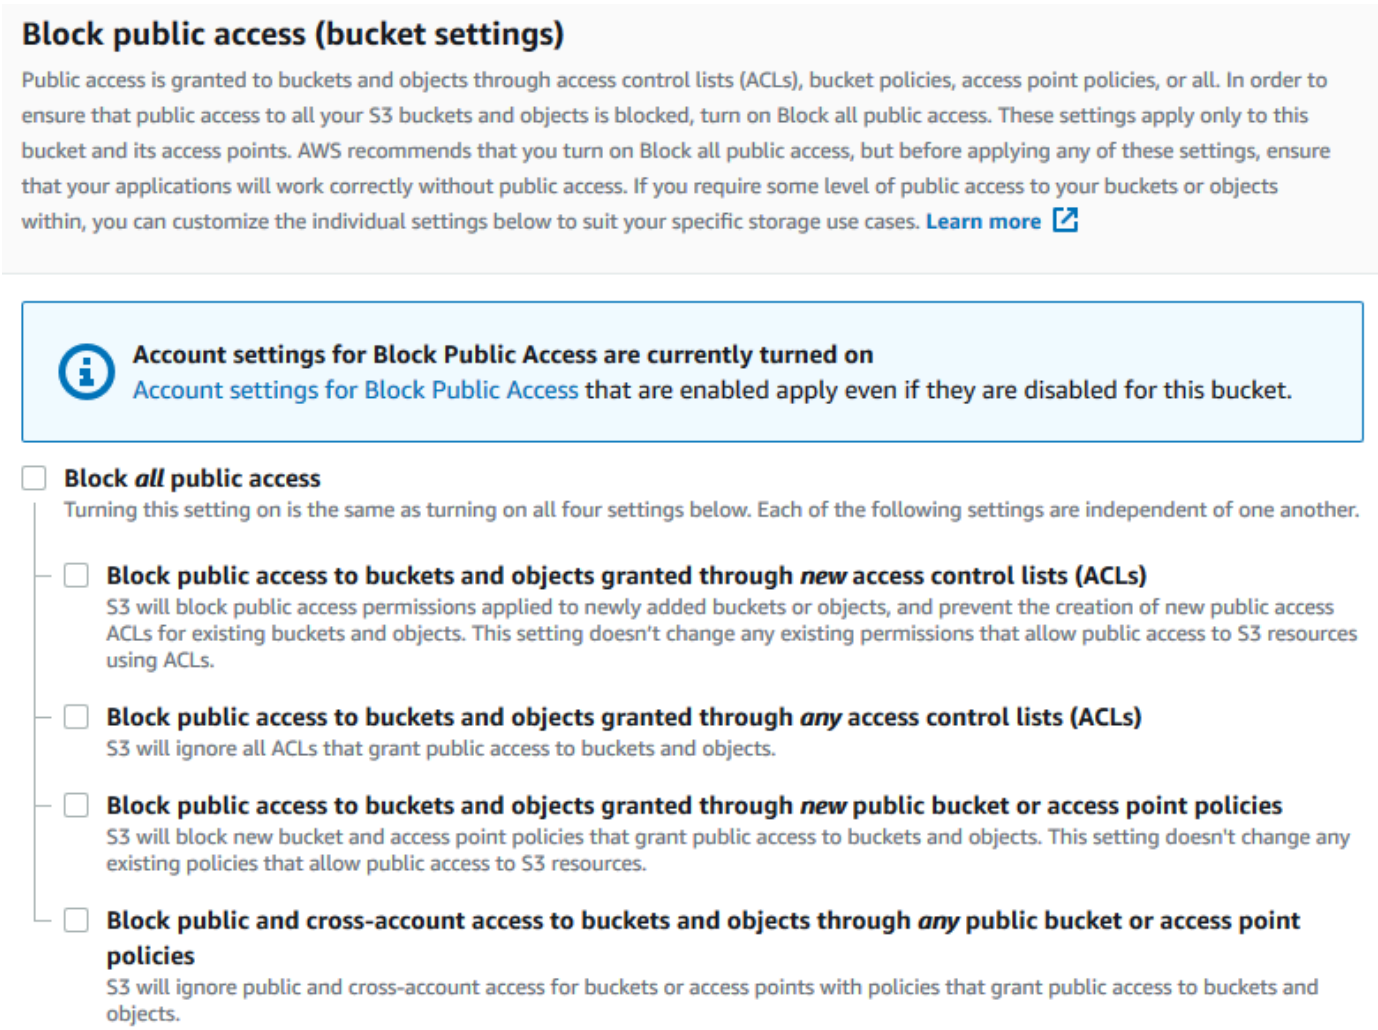
3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see Uploading objects.



Step 8: Edit S3 Block Public Access settings

In this example, you edit block public access settings for the domain bucket (`example.com`) to allow public access.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 9: Attach a bucket policy

In this example, you attach a bucket policy to the domain bucket (`example.com`) to allow public read access. You replace the *`Bucket-Name`* in the example bucket policy with the name of your domain bucket, for example `example.com`.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

In the next step, you can figure out your website endpoints and test your domain endpoint.

Step 10: Test your domain endpoint

After you configure your domain bucket to host a public website, you can test your endpoint. For more information, see Website endpoints. You can only test the endpoint for your domain bucket because your subdomain bucket is set up for website redirect and not static website hosting.

> **Note**
>
> Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.
> For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

   Your index document opens in a separate browser window.

In the next step, you use Amazon Route 53 to enable customers to use both of your custom URLs to navigate to your site.

Step 11: Add alias records for your domain and subdomain

In this step, you create the alias records that you add to the hosted zone for your domain maps `example.com` and `www.example.com`. Instead of using IP addresses, the alias records use the

Amazon S3 website endpoints. Amazon Route 53 maintains a mapping between the alias records and the IP addresses where the Amazon S3 buckets reside. You create two alias records, one for your root domain and one for your subdomain.

Add an alias record for your root domain and subdomain

To add an alias record for your root domain (`example.com`)

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.

   > **Note**
   >
   > If you don't already use Route 53, see Step 1: Register a domain in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create record**.
5. Choose **Switch to wizard**.

   > **Note**
   >
   > If you want to use quick create to create your alias records, see Configuring Route 53 to route traffic to an S3 Bucket.

6. Choose **Simple routing**, and choose **Next**.
7. Choose **Define simple record**.
8. In **Record name**, accept the default value, which is the name of your hosted zone and your domain.
9. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
10. Choose the Region.
11. Choose the S3 bucket.

    The bucket name should match the name that appears in the **Name** box. In the **Choose S3 bucket** list, the bucket name appears with the Amazon S3 website endpoint for the Region

where the bucket was created, for example, `s3-website-us-west-1.amazonaws.com (example.com)`.

Choose S3 bucket lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, **`s3-website-us-west-2.amazonaws.com`**. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.

12. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
13. For **Evaluate target health**, choose **No**.
14. Choose **Define simple record**.

To add an alias record for your subdomain (`www.example.com`)

1. Under **Configure records**, choose **Define simple record**.
2. In **Record name** for your subdomain, type `www`.
3. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
4. Choose the Region.
5. Choose the S3 bucket, for example, `s3-website-us-west-2.amazonaws.com (www.example.com)`.

   If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, **`s3-website-us-west-2.amazonaws.com`**. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.
6. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Evaluate target health**, choose **No**.
8. Choose **Define simple record**.

9. On the **Configure records** page, choose **Create records**.

> **Note**
>
> Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Add an alias record for your root domain and subdomain (old Route 53 console)

To add an alias record for your root domain (`example.com`)

The Route 53 console has been redesigned. In the Route 53 console you can temporarily use the old console. If you choose to work with the old Route 53 console, use the procedure below.

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.

   > **Note**
   >
   > If you don't already use Route 53, see Step 1: Register a domain in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted Zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create Record Set**.
5. Specify the following values:

   Name

   Accept the default value, which is the name of your hosted zone and your domain.

   For the root domain, you don't need to enter any additional information in the **Name** field.

   Type

   Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose your bucket name.

The bucket name should match the name that appears in the **Name** box. In the **Alias Target** listing, the bucket name is followed by the Amazon S3 website endpoint for the Region where the bucket was created, for example `example.com (s3-website-us-west-2.amazonaws.com)`. **Alias Target** lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Alias Target** listing, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2`. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

6. Choose **Create**.

To add an alias record for your subdomain (`www.example.com`)

1. In the hosted zone for your root domain (`example.com`), choose **Create Record Set**.
2. Specify the following values:

Name

For the subdomain, enter `www` in the box.

Type

Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose the same bucket name that appears in the **Name** field—for example, `www.example.com (s3-website-us-west-2.amazonaws.com)`.

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

3. Choose **Create**.

> **Note**
>
> Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Step 12: Test the website

Verify that the website and the redirect work correctly. In your browser, enter your URLs. In this example, you can try the following URLs:

- **Domain** (`http://example.com`) – Displays the index document in the `example.com` bucket.
- **Subdomain** (`http://www.example.com`) – Redirects your request to `http://example.com`. You see the index document in the `example.com` bucket.

If your website or redirect links don't work, you can try the following:

- **Clear cache** – Clear the cache of your web browser.
- **Check name servers** – If your web page and redirect links don't work after you've cleared your cache, you can compare the name servers for your domain and the name servers for your hosted zone. If the name servers don't match, you might need to update your domain name servers to match those listed under your hosted zone. For more information, see Adding or changing name servers and glue records for a domain.

After you've successfully tested your root domain and subdomain, you can set up an Amazon CloudFront distribution to improve the performance of your website and provide logs that you can use to review website traffic. For more information, see Speeding up your website with Amazon CloudFront.

Speeding up your website with Amazon CloudFront

You can use Amazon CloudFront to improve the performance of your Amazon S3 website. CloudFront makes your website files (such as HTML, images, and video) available from data centers around the world (known as *edge locations*). When a visitor requests a file from your website, CloudFront automatically redirects the request to a copy of the file at the nearest edge location. This results in faster download times than if the visitor had requested the content from a data center that is located farther away.

CloudFront caches content at edge locations for a period of time that you specify. If a visitor requests content that has been cached for longer than the expiration date, CloudFront checks the origin server to see if a newer version of the content is available. If a newer version is available, CloudFront copies the new version to the edge location. Changes that you make to the original content are replicated to edge locations as visitors request the content.

Using CloudFront without Route 53

The tutorial on this page uses Route 53 to point to your CloudFront distribution. However, if you want to serve content hosted in an Amazon S3 bucket using CloudFront without using Route 53, see Amazon CloudFront Tutorials: Setting up a Dynamic Content Distribution for Amazon S3. When you serve content hosted in an Amazon S3 bucket using CloudFront, you can use any bucket name, and both HTTP and HTTPS are supported.

Automating set up with an CloudFormation template

For more information about using an CloudFormation template to configure a secure static website that creates a CloudFront distribution to serve your website, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

Topics

- Step 1: Create a CloudFront distribution
- Step 2: Update the record sets for your domain and subdomain
- (Optional) Step 3: Check the log files

Step 1: Create a CloudFront distribution

First, you create a CloudFront distribution. This makes your website available from data centers around the world.

To create a distribution with an Amazon S3 origin

1. Open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. Choose **Create Distribution**.
3. On the **Create Distribution** page, in the **Origin Settings** section, for **Origin Domain Name**, enter the Amazon S3 website endpoint for your bucket—for example, **`example.com.s3-website.us-west-1.amazonaws.com`**.

   CloudFront fills in the **Origin ID** for you.
4. For **Default Cache Behavior Settings**, keep the values set to the defaults.

   With the default settings for **Viewer Protocol Policy**, you can use HTTPS for your static website. For more information these configuration options, see Values that You Specify When You Create or Update a Web Distribution in the *Amazon CloudFront Developer Guide*.
5. For **Distribution Settings**, do the following:

   a. Leave **Price Class** set to **Use All Edge Locations (Best Performance)**.

   b. Set **Alternate Domain Names (CNAMEs)** to the root domain and `www` subdomain. In this tutorial, these are `example.com` and `www.example.com`.

> **Important**
>
> Before you perform this step, note the requirements for using alternate domain names, in particular the need for a valid SSL/TLS certificate.

c. For **SSL Certificate**, choose **Custom SSL Certificate (example.com)**, and choose the custom certificate that covers the domain and subdomain names.

   For more information, see SSL Certificate in the *Amazon CloudFront Developer Guide*.

d. In **Default Root Object**, enter the name of your index document, for example, `index.html`.

   If the URL used to access the distribution doesn't contain a file name, the CloudFront distribution returns the index document. The **Default Root Object** should exactly match the name of the index document for your static website. For more information, see Configuring an index document.

e. Set **Logging** to **On**.

> **Important**
>
> When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

f. For **Bucket for Logs**, choose the logging bucket that you created.

   For more information about configuring a logging bucket, see (Optional) Logging web traffic.

g. If you want to store the logs that are generated by traffic to the CloudFront distribution in a folder, in **Log Prefix**, enter the folder name.

h. Keep all other settings at their default values.

6. Choose **Create Distribution**.
7. To see the status of the distribution, find the distribution in the console and check the **Status** column.

   A status of `InProgress` indicates that the distribution is not yet fully deployed.

   After your distribution is deployed, you can reference your content with the new CloudFront domain name.
8. Record the value of **Domain Name** shown in the CloudFront console, for example, `dj4p1rv6mvubz.cloudfront.net`.
9. To verify that your CloudFront distribution is working, enter the domain name of the distribution in a web browser.

   If your website is visible, the CloudFront distribution works. If your website has a custom domain registered with Amazon Route 53, you will need the CloudFront domain name to update the record set in the next step.

Step 2: Update the record sets for your domain and subdomain

Now that you have successfully created a CloudFront distribution, update the alias record in Route 53 to point to the new CloudFront distribution.

To update the alias record to point to a CloudFront distribution

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation, choose **Hosted zones**.
3. On the **Hosted Zones** page, choose the hosted zone that you created for your subdomain, for example, `www.example.com`.
4. Under **Records**, select the *A* record that you created for your subdomain.
5. Under **Record details**, choose **Edit record**.
6. Under **Route traffic to**, choose **Alias to CloudFront distribution**.
7. Under **Choose distribution**, choose the CloudFront distribution.
8. Choose **Save**.
9. To redirect the *A* record for the root domain to the CloudFront distribution, repeat this procedure for the root domain, for example, `example.com`.

The update to the record sets takes effect within 2–48 hours.

10. To see whether the new *A* records have taken effect, in a web browser, enter your subdomain URL, for example, `http://www.example.com`.

    If the browser no longer redirects you to the root domain (for example, `http://example.com`), the new A records are in place. When the new *A* record has taken effect, traffic routed by the new *A* record to the CloudFront distribution is not redirected to the root domain. Any visitors who reference the site by using `http://example.com` or `http://www.example.com` are redirected to the nearest CloudFront edge location, where they benefit from faster download times.

    > **Tip**
    >
    > Browsers can cache redirect settings. If you think the new *A* record settings should have taken effect, but your browser still redirects `http://www.example.com` to `http://example.com`, try clearing your browser history and cache, closing and reopening your browser application, or using a different web browser.

(Optional) Step 3: Check the log files

The access logs tell you how many people are visiting the website. They also contain valuable business data that you can analyze with other services, such as Amazon EMR.

CloudFront logs are stored in the bucket and folder that you choose when you create a CloudFront distribution and enable logging. CloudFront writes logs to your log bucket within 24 hours from when the corresponding requests are made.

To see the log files for your website

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the logging bucket for your website.
3. Choose the CloudFront logs folder.
4. Download the `.gzip` files written by CloudFront before opening them.

   If you created your website only as a learning exercise, you can delete the resources that you allocated so that you no longer accrue charges. To do so, see Cleaning up your example resources. After you delete your AWS resources, your website is no longer available.

Cleaning up your example resources

If you created your static website as a learning exercise, you should delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available.

Tasks

- Step 1: Delete the Amazon CloudFront distribution
- Step 2: Delete the Route 53 hosted zone
- Step 3: Disable logging and delete your S3 bucket

Step 1: Delete the Amazon CloudFront distribution

Before you delete an Amazon CloudFront distribution, you must disable it. A disabled distribution is no longer functional and does not accrue charges. You can enable a disabled distribution at any time. After you delete a disabled distribution, it is no longer available.

To disable and delete a CloudFront distribution

1. Open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. Select the distribution that you want to disable, and then choose **Disable**.
3. When prompted for confirmation, choose **Yes, Disable**.
4. Select the disabled distribution, and then choose **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Step 2: Delete the Route 53 hosted zone

Before you delete the hosted zone, you must delete the record sets that you created. You don't need to delete the NS and SOA records; these are automatically deleted when you delete the hosted zone.

To delete the record sets

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the list of domain names, select your domain name, and then choose **Go to Record Sets**.
3. In the list of record sets, select the *A* records that you created.

The type of each record set is listed in the **Type** column.

4. Choose **Delete Record Set**.
5. When prompted for confirmation, choose **Confirm**.

To delete a Route 53 hosted zone

1. Continuing from the previous procedure, choose **Back to Hosted Zones**.
2. Select your domain name, and then choose **Delete Hosted Zone**.
3. When prompted for confirmation, choose **Confirm**.

Step 3: Disable logging and delete your S3 bucket

Before you delete your S3 bucket, make sure that logging is disabled for the bucket. Otherwise, AWS continues to write logs to your bucket as you delete it.

To disable logging for a bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Under **Buckets**, choose your bucket name, and then choose **Properties**.
3. From **Properties**, choose **Logging**.
4. Clear the **Enabled** check box.
5. Choose **Save**.

Now, you can delete your bucket. For more information, see Deleting a general purpose bucket.

Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket

We recommend that you use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. Deploying a static website using Amplify Hosting provides you with the following benefits and features:

- **Deployment to the AWS content delivery network (CDN) powered by Amazon CloudFront** - CloudFront is a web service that speeds up distribution of your static and dynamic web content to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations. When a user requests content that you're serving with CloudFront, the request is routed to the edge location that provides the lowest latency (time delay), so that content is delivered with the best possible performance, increased reliability and availability. For more information, see How CloudFront delivers content in the *Amazon CloudFront Developer Guide*.
- **HTTPS support** - Provides secure communication and data transfer between your website and a user's web browser.
- **Custom domains** - Easily connect your website to a custom URL purchased from a domain registrar such as Amazon Route 53.
- **Custom SSL certificates** - When you set up your custom domain, you can use the default managed certificate that Amplify provisions for you or you can use your own custom certificate purchased from the third-party certificate authority of your choice.
- **Built in metrics and CloudWatch monitoring** - Monitor traffic, errors, data transfer, and latency for your website.
- **Password protection** - Restrict access to your website, by setting up a username and password requirement in the Amplify console.
- **Redirects and rewrites** - Create redirect and rewrite rules in the Amplify console to enable a web server to reroute navigation from one URL to another.

When you deploy your application from an Amazon S3 general purpose bucket to Amplify Hosting, AWS charges are based on Amplify's pricing model. For more information, see AWS Amplify Pricing.

Important

Amplify Hosting is not available in all of the AWS Regions where Amazon S3 is available. To deploy a static website to Amplify Hosting, the Amazon S3 general purpose bucket containing your website must be located in a region where Amplify is available. For the list of regions where Amplify is available, see Amplify endpoints in the *Amazon Web Services General Reference*.

You can start the deployment process from the Amazon S3 console, the Amplify console, the AWS CLI, or the AWS SDKs. You can only deploy to Amplify from a general purpose bucket located in your own account. Amplify doesn't support cross-account bucket access.

Use the following instructions to deploy a static website from an Amazon S3 general purpose bucket to Amplify Hosting starting from the Amazon S3 console.

Deploying a static website to Amplify from the S3 console

To deploy a static website from the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the general purpose bucket that contains the website you want to deploy to Amplify Hosting.
4. Choose the **Properties** tab.
5. Under **Static website hosting**, choose **Create Amplify app**. At this step, the deployment process will move to the Amplify console.
6. On the **Deploy with S3** page, do the following steps.
   a. For **App name**, enter the name of your app or website.
   b. For **Branch name**, enter the name of your app's backend.
   c. For **S3 location of objects to host**, either enter the directory path to your general purpose bucket or choose **Browse S3** to locate and select it.
7. Choose **Save and deploy**.

> **Note**
>
> If you update any of the objects for a static website in your general purpose bucket hosted on Amplify, you must redeploy the application to Amplify Hosting to cause the changes to take effect. Amplify Hosting doesn't automatically detect changes to your bucket. For more information, see Updating a static website deployed to Amplify from an S3 bucket in the *AWS Amplify Hosting User Guide*.

To start directly from the Amplify console, see Deploying a static website from S3 using the Amplify console in the *AWS Amplify Hosting User Guide*.

To get started using the AWS SDKs, see Creating a bucket policy to deploy a static website from S3 using the AWS SDKs in the *AWS Amplify Hosting User Guide*.

Tagging for cost allocation or attribute-based access control (ABAC)

An AWS tag is a key-value pair that holds metadata. You attach the tags to your Amazon S3 resources, such as buckets. You can tag resources when you create them or manage tags on existing resources. There is no additional charge for using tags beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

How tags work

Amazon S3 support two types of tags:

- **AWS-generated tags:** AWS automatically applies these tags, and you cannot modify them or remove them. To learn more about AWS-generated tags, see Using AWS-generated tags.
- **User-defined tags:** You apply these tags to your S3 resources and manage them.

User-defined tags

A user-defined tag is a tag key-value pair that you use to label your resources. User-defined tags consist of a required key and an optional value. These are the main components of a user-defined tag:

The tag key

The tag key is the required name of the tag. For example, `project` is the tag key in the following tag key-value pair:

Key	Value
`project`	`Trinity`

The tag key is a case-sensitive string that must contain between 1 and 128 Unicode characters. Keys can only contain Unicode letters or numbers, white space, and the following symbols:

- _ - underscore

- `.` - period
- `:` - colon
- `/` - forward slash
- `=` - equal sign
- `+` - plus sign
- `@` - at sign
- `-` - dash

The tag value

The tag value is an optional string. For example, `Trinity` is the tag value in this tag key-value pair:

Key	Value
`project`	`Trinity`

The tag value is a case-sensitive string that can contain between 0 and 256 Unicode characters. Values can only contain Unicode letters or numbers, white space, and the following symbols:

- `_` - underscore
- `.` - period
- `:` - colon
- `/` - forward slash
- `=` - equal sign
- `+` - plus sign
- `@` - at sign
- `-` - dash

For details on the characters allowed in user-defined tags and other restrictions, see User-Defined Tag Restrictions in the *AWS Billing and Cost Management User Guide*.

The tag set

Each S3 resource has one *tag set* that contains all of the tag key and value pairs that are assigned to that bucket. A tag set can be empty, or it can contain as many as 50 user-defined tags, except in the case of tagging objects. Objects can have up to 10 tags only.

While each key must be unique in a tag set, you can use the same value multiple times. For example, you can have the same value, `Trinity`, for following two tag keys:

Key	Value
`project`	`Trinity`
`cost-center`	`Trinity`

When you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS does not apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, modify, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

Common ways to use tags

Use tags on your S3 resources for:

1. **Cost allocation** – Track storage costs by bucket tag in AWS Billing and Cost Management.
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 resources based on their tags.

> **Note**
>
> You can use the same tags for both cost allocation and access control.

Using tags for cost allocation

Track your Amazon S3 storage costs by applying tags to S3 resources and activating these tags for cost allocation.

To start tracking costs:

1. Add tags to your S3 resources or use existing tags. For example, you can label buckets with a tag that identifies a project or a group of projects.
2. Activate the tags for cost allocation in the AWS Billing and Cost Management console. See Activating user-defined cost allocation tags in the *AWS Billing and Cost Management User Guide*. You can activate user-defined or AWS-generated tags. For more information, see Organizing and tracking costs using AWS cost allocation tags.

AWS uses the activated tags to organize your resource costs in various billing and cost management tools, such as:

- **Cost allocation report**

  Provides a high-level view of costs organized by your activated tags. For more information, see Using the monthly cost allocation report in the *AWS Billing User Guide*.
- **Cost and Usage Report (CUR)**

  Provides the most detailed set of AWS cost and usage data, including tag-based cost breakdowns. For more information, see What are AWS Cost and Usage Reports? in the *AWS Data Export User Guide*.

Amazon S3 resources that support tracking costs with tags

The following Amazon S3 resources support storage cost tracking using tags.

- **S3 general purpose buckets**

  For more information, see Using tags with S3 general purpose buckets.
- **S3 Directory buckets**

  For more information, see Using tags with S3 directory buckets.
- **S3 tables**

For more information, see Using tags with S3 tables.

- **S3 vector index**

  For more information, see Using tags with S3 vector indexes

Using tags for attribute-based access control (ABAC)

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes, i.e., tags. You can attach tags to AWS Identity and Access Management (IAM) entities (users or roles) and to AWS resources, such as Amazon S3 Access Points and directory buckets. Then, you control permissions to these resources using tag-based conditions in access control policies to allow or deny operations when these conditions are met.

With ABAC, you use tag-based condition keys in your AWS organizations, IAM, and S3 resource policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 resources based on the bucket's tags by using condition keys.

Supported condition keys

You can use the following AWS condition keys for all Amazon S3 resources that support ABAC.

- `aws:ResourceTag/key-name`
- `aws:RequestTag/key-name`
- `aws:TagKeys`

Some resources support additional Amazon S3 condition keys. For a complete list of condition keys that can be used for ABAC and example policies, see the following tagging topics for the resource.

Amazon S3 resources that support ABAC

The following Amazon S3 resources support attribute-based access control (ABAC) using tags.

- **S3 general purpose buckets**

  For more information, see Using tags with S3 general purpose buckets.

- **Access points**

  For more information, see Using tags with S3 Access Points for general purpose buckets and Using tags with S3 Access Points for directory buckets.

- **Batch operation jobs**

  For more information, see Controlling access and labeling jobs using tags.

- **S3 Directory buckets**

  For more information, see Using tags with S3 directory buckets.

- **Objects**

  For more information, see Tagging your objects.

- **S3 Access Grants**

  For more information, see Managing tags for S3 Access Grants.

- **S3 Storage Lens Groups**

  For more information, see Managing AWS resource tags with Storage Lens groups.

- **S3 table buckets and tables**

  For more information, see Using tags with S3 table buckets and Using tags with S3 tables.

- **S3 Vector buckets and indexes**

  For more information, see Using tags with S3 vector buckets and Using tags with S3 vector indexes.

Planning your tagging strategy

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the Tagging Best Practices AWS Whitepaper.

Best practices for tagging Amazon S3 resources

When you use tags, we recommend that you adhere to the following best practices:

- Document conventions for tag use that are followed by all teams in your organization. In particular, ensure the names are both descriptive and consistent. For example, standardize on the format `environment:prod` rather than tagging some resources with `env:production`.

  > **Important**
  >
  > Do not store personally identifiable information (PII) or other confidential or sensitive information in tags.

- Automate tagging to ensure consistency. For example, you can include tags in an CloudFormation template. When you create resources with the template, the resources are tagged automatically.
- Use tags only when necessary. Avoid unnecessary tag proliferation and complexity.
- Review tags periodically for relevance and accuracy. Remove or modify outdated tags as needed.
- Consider creating tags with the AWS Tag Editor in the AWS Management Console. You can use the Tag Editor to add tags to multiple supported AWS resources, including Amazon S3 resources, at the same time. For more information, see Tag Editor in the *AWS Resource Groups User Guide*.

Managing tags for Amazon S3 resources

For more information on how to manage tags for Amazon S3 resources, see the following:

- Using tags with S3 Access Points for general purpose buckets
- Using tags with S3 Access Points for directory buckets
- Controlling access and labeling jobs using tags
- Using tags with S3 directory buckets
- Using cost allocation S3 bucket tags
- Tagging your objects
- Managing tags for S3 Access Grants
- Managing AWS resource tags with Storage Lens groups
- Using tags with S3 general purpose buckets.
- Using tags with S3 vector buckets
- Using tags with S3 vector indexes

Using tags with S3 general purpose buckets

An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 general purpose buckets. You can tag S3 buckets when you create them or manage tags on existing buckets. For general information about tags, see Tagging for cost allocation or attribute-based access control (ABAC).

> **Note**
>
> There is no additional charge for using tags on buckets beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

Common ways to use tags with buckets

Use tags on your S3 buckets for:

1. **Cost allocation** – Track storage costs by bucket tag in AWS Billing and Cost Management. For more information, see Using tags for cost allocation.
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 buckets based on their tags. For more information, see Using tags for ABAC.

> **Note**
>
> For general purpose buckets, ABAC is not enabled by default. To enable ABAC for general purpose buckets, see Enabling ABAC in general purpose buckets. For Amazon S3 resources such as access points and directory buckets, ABAC is enabled by default. You can use the same tags for both cost allocation and access control.

ABAC for S3 general purpose buckets

Amazon S3 general purpose buckets support attribute-based access control (ABAC) using tags. Use tag-based condition keys in your AWS organizations, IAM, and S3 bucket policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 buckets based on the bucket's tags by using the following global condition keys:

- `aws:ResourceTag/key-name`
  - Use this condition key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. S3 evaluates this condition key only after you enable ABAC on your bucket. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `Dept` with the value `Marketing`. For more information, see Controlling access to AWS resources.
- `aws:RequestTag/key-name`
  - Use this condition key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `Dept` and that it has the value `Accounting`. For more information, see Controlling access during AWS requests. You can use this condition key to restrict which tag key-value pairs can be passed during the `TagResource` and `CreateBucket` API operations.
- `aws:TagKeys`
  - Use this condition key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see Controlling access based on tag keys.
- `s3:BucketTag/tag-key`
  - Use this condition key to grant permissions to specific data in buckets using tags. This condition key is applicable only after ABAC is enabled on your bucket. When accessing a bucket by using an access point, the `aws:ResourceTag/tag-key` condition key references the tags on the bucket both when authorizing against the access point and the bucket. The `s3:BucketTag/tag-key` will reference the tags only of the bucket it is being authorized against.

> **Note**
>
> When creating buckets with tags, note that tag-based conditions to access your bucket using aws:ResourceTag and s3:BucketTag condition keys are applicable only after you enable ABAC on the bucket. To learn more, see Enabling ABAC in general purpose buckets.

Example ABAC policies for buckets

See the following example ABAC policies for Amazon S3 buckets.

1.1 - IAM policy to create or modify buckets with specific tags

In this IAM policy, users or roles with this policy can only create S3 buckets if they tag the bucket with the tag key `project` and tag value `Trinity` in the bucket creation request. They can also add or modify tags on existing S3 buckets as long as the `TagResource` request includes the tag key-value pair `project:Trinity`. This policy does not grant read, write, or delete permissions on the buckets or its objects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateBucketWithTags",
      "Effect": "Allow",
      "Action": [
        "s3:CreateBucket",
        "s3:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": [
            "Trinity"
          ]
        }
      }
    }
  ]
}
```

1.2 - Bucket policy to restrict operations

In this bucket policy, IAM principals (users and roles) are denied `s3:ListBucket`, `s3:GetObject`, and `s3:PutObject` actions on the bucket only if value of the `project` tag on the bucket matches the value of the `project` tag on the principal.

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "DenyObjectOperations",
            "Effect": "Deny",
            "Principal": "*",
            "Action": ["s3:ListBucket",
                       "s3:GetObject",
                       "s3:PutObject"],
            "Resource": "arn:aws:s3:::aws-s3-demo/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
                }
            }
        }
    ]
}
```

1.3 - IAM policy to modify tags on existing resources

In this IAM policy, IAM principals (users or roles) can modify tags on a bucket only if the value of the bucket's `project` tag matches the value of the principal's `project` tag. Only the four tags `project`, `environment`, `owner`, and `cost-center` specified in the `aws:TagKeys` condition keys are permitted for these buckets. This helps enforce tag governance, prevents unauthorized tag modifications, and keeps the tagging schema consistent across your buckets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceTaggingRulesOnModification",
      "Effect": "Allow",
      "Action": [
        "s3:TagResource",
        "s3:CreateBucket"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "project",
            "environment",
            "owner",
```

```
            "cost-center"
          ]
        }
      }
    }
  ]
}
```

1.4 - Using the s3:BucketTag condition key

In this IAM policy, the condition statement allows access to the `aws-s3-demo` bucket's data only if the bucket has the tag key `Environment` and tag value `Production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessViaSpecificBucket",
      "Effect": "Allow",
      "Action": "*",
      "Resource": ["arn:aws:s3:::aws-s3-demo","arn:aws:s3:::aws-s3-demo/*"],
      "Condition": {
        "StringEquals": {
          "s3:BucketTag/Environment": "Production"
        }
      }
    }
  ]
}
```

Managing tags for general purpose buckets

You can add or manage tags for S3 buckets using the Amazon S3 Console, the AWS Command Line Interface (CLI), the AWS SDKs, or using the S3 APIs: TagResource, UntagResource, and ListTagsForResource. For more information, see:

Enabling ABAC in general purpose buckets

Attribute-based access control (ABAC) is an authorization strategy that you use to define permissions based on attributes, i.e., tags. By default, ABAC is disabled for all Amazon S3 general purpose buckets. To use ABAC for general purpose buckets, you must enable it.

Before enabling ABAC for your general purpose bucket, we recommend that you first complete the tasks described in the following topics:

Topics

- Auditing your policies before enabling ABAC

Auditing your policies before enabling ABAC

Before you enable ABAC for your bucket, if your bucket has tags, audit your access control policies to review if tag-based conditions reference any of the existing tags on your buckets. If they do, confirm that these policies are set up as intended and that enabling tag-based access control does not create unintentional authorization changes to your Amazon S3 workflows. Doing so will help you ensure that your policies function as intended after ABAC is enabled on your buckets. For examples of using attribute-based conditions with tags, see Using tags with S3 general purpose buckets.

Including the required permissions in your IAM policies

You need the following Amazon S3 permissions to enable ABAC for your bucket:

- `s3:PutBucketAbac` – Update the ABAC status for your general purpose bucket.
- `s3:GetBucketAbac` – View the ABAC status for your general purpose bucket

After you enable ABAC, the permissions you previously used to add tags to a bucket or delete tags from a bucket, `PutBucketTagging` or `DeleteBucketTagging`, will no longer work. Instead, use the `TagResource` and *`UntagResource`* APIs to perform these tasks.

We recommend you use `TagResource` and `UntagResource` APIs to manage tagging before enabling ABAC on your buckets. The Amazon S3 Console and CloudFormation now use the `TagResource` and `UntagResource` APIs by default. You can also disable ABAC on your bucket by using the `PutBucketAbac` API. You can use `GetBucketTagging` to list tags on your buckets. This API will continue to work after you enable ABAC for your buckets. Alternatively you can also use `ListTagsForResource` to list all tags on your buckets.

You will need the following permissions to apply tags to and remove them from general purpose buckets.

- `s3:TagResource` - Add tags to an AWS resource, such as an Amazon S3 general purpose bucket.
- `s3:UntagResource` - Remove tags from an AWS resource, such as an Amazon S3 general purpose bucket.
- `s3:ListTagsForResource` - View the tags applied to an AWS resource, such as an Amazon S3 general purpose bucket.

The following IAM policy grants the permission to enable ABAC and view its status for your bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutBucketAbac",
        "s3:GetBucketAbac"
      ],
      "Resource": "arn:aws:s3:::my-s3-bucket/*"
    }
  ]
}
```

For more information on tagging general purpose buckets and example ABAC policies for general purpose buckets, see Using tags with S3 general purpose buckets.

Steps

If you have `s3:PutBucketAbac` permission for a general purpose bucket, you can enable ABAC for the bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To enable ABAC for a general purpose bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.

4. Choose the **Properties** tab.
5. In the **Bucket ABAC** panel, and choose **Edit**.
6. Choose the **Enable** toggle.
7. Review and acknowledge the permissions you will need to manage tags after you enable ABAC: `TagResource`, `UntagResource`, and `ListTagsForResource`.
8. Choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add enable ABAC for a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *`user input placeholders`* with your own information.

```
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.AbacStatus;
import software.amazon.awssdk.services.s3.model.GetBucketAbacRequest;
import software.amazon.awssdk.services.s3.model.GetBucketAbacResponse;
import software.amazon.awssdk.services.s3.model.PutBucketAbacRequest;
import software.amazon.awssdk.services.s3.model.PutBucketAbacResponse;
import software.amazon.awssdk.regions.Region;

public class BucketAbac {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
            .region(region)
            .build();

        putBucketAbac(s3, "amzn-s3-demo-bucket", "Enabled");
        getBucketAbac(s3, "amzn-s3-demo-bucket");

        putBucketAbac(s3, "amzn-s3-demo-bucket", "Disabled");
        getBucketAbac(s3, "amzn-s3-demo-bucket");
    }

    /**
     * Sets the ABAC (Attribute-Based Access Control) status for a specified S3
 bucket.
     *
```

```
     * @param s3 The S3Client instance to use for the API call
     * @param bucketName The name of the S3 bucket to update
     * @param status The desired ABAC status ("Enabled" or "Disabled")
    */
    public static void putBucketAbac(S3Client s3, String bucketName, String status)
 {
       try {
            AbacStatus abacStatus = AbacStatus.builder()
                .abacStatus(status)
                .build();
            PutBucketAbacReqquest request = PutBucketAbacRequest.builder()
                .bucket(bucketName)
                .abacStatus(abacStatus)
                .build();
            s3.putBucketAbac(request);
        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }

    /**
     * Retrieves the current ABAC (Attribute-Based Access Control) status for a
 specified S3 bucket.
     *
     * @param s3 The S3Client instance to use for the API call
     * @param bucketName The name of the S3 bucket to query
    */
    public static void getBucketAbac(S3Client s3, String bucketName) {
       try {
            GetBucketAbacReqquest request = GetBucketAbacRequest.builder()
                .bucket(bucketName)
                .build();
            GetBucketAbacResponse response = s3.getBucketAbac(request);
        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

This example shows you how to add enable ABAC for a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the `user input placeholders` with your own information.

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- PutBucketAbac

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to enable ABAC for a general purpose bucket by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
# Enable ABAC on a general purpose bucket

aws s3api put-bucket-abac --bucket amzn-s3-demo-bucket --abac-status Status=Enabled --
region us-east-2

# Disable ABAC on a general purpose bucket

aws s3api put-bucket-abac --bucket amzn-s3-demo-bucket --abac-status Status=Disabled --
region us-east-2

# Get ABAC status on a general purpose bucket

aws s3api get-bucket-abac --bucket amzn-s3-demo-bucket --region us-east-2
```

Creating general purpose buckets with tags

You can tag Amazon S3 general purpose buckets when you create them. There is no additional charge for using tags on buckets beyond the standard S3 API request rates. For more information,

see Amazon S3 pricing. For more information about tagging buckets, see Using tags with S3 general purpose buckets.

Permissions

To create a bucket with tags, you must have the following permissions:

- `s3:CreateBucket`
- `s3:TagResource`

Amazon S3 Console and CloudFormation now use this capability to create buckets with tags.

Troubleshooting errors

If you encounter an error when attempting to create a bucket with tags, you can do the following:

- Verify that you have the required Permissions to create the bucket and add a tag to it.
- Check your IAM policy for `aws:TagKeys` or `aws:RequestTag/key-name` condition keys. You might be required to label your buckets only with specific tag keys and values. For more information, see Using tags for attribute-based access control (ABAC).

> **Note**
>
> Amazon S3 and CloudFormation now use this capability to create buckets with tags. When creating buckets with tags, note that tag-based conditions to access your bucket using `aws:ResourceTag` and `s3:BucketTag` condition keys are applicable only after you enable ABAC on the bucket. To learn more, see Enabling ABAC in general purpose buckets.

Steps

You can create a bucket with tags applied by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create a bucket with tags using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **buckets**.
3. Choose **create bucket** to create a new bucket.
4. Create a bucket a general purpose bucket as you normally would; see Creating a general purpose bucket.
5. On the **Create bucket** page, **Tags** is an option when creating a new bucket.
6. Enter a name for the bucket. For more information, see General purpose bucket naming rules.
7. Choose **Add new Tag** to open the Tags editor and enter a tag key-value pair. The tag key is required, but the value is optional.
8. To add another tag, select **Add new Tag** again. You can enter up to 50 tag key-value pairs.
9. After you complete specifying the options for your new bucket, choose **Create bucket**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to create a general purpose bucket with tags by using the AWS SDK for Java 2.x. To use the command replace the *`user input placeholders`* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.BucketLocationConstraint;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateBucketResponse;
import software.amazon.awssdk.services.s3.model.Tag;

public class CreateBucketWithTagsExample {
    public static void createBucketWithTagsExample() {
        S3Client s3 = S3Client.builder().region(Region.US_WEST_2).build();

        CreateBucketConfiguration bucketConfiguration =
 CreateBucketConfiguration.builder()
                .locationConstraint(BucketLocationConstraint.US_WEST_2)
                .tags(Tag.builder().key("MyTagKey").value("MyTagValue").build())
                .build();
```

```
        CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
                .bucket("mybucket")
                .createBucketConfiguration(bucketConfiguration)
                .build();

        CreateBucketResponse response = s3.createBucket(createBucketRequest);
        System.out.println("Status code (should be 200):");
        System.out.println(response.sdkHttpResponse().statusCode());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for creating a general purpose bucket with tags, see the following section in the *Amazon Simple Storage Service API Reference*:

- CreateBucket

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to create a bucket with tags by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

When you create a bucket, you must provide configuration details and use the following naming convention: *`amzn-s3-demo-bucket`*

Request:

```
aws s3api create-bucket \
--bucket mybucket \
--create-bucket-configuration 'LocationConstraint=us-
west-2,Tags=[{Key=MyTagKey,Value=MyTagValue}]' --region us-west-2"
```

Response:

```
{
  "Location": "http://mybuckets3.amazonaws.com/"
}
```

Adding a tag to a bucket

You can add tags to Amazon S3 buckets and modify these tags. There is no additional charge for using tags on buckets beyond the standard S3 API request rates. For more information, see Amazon S3 pricing. For more information about tagging buckets, see Using tags with S3 general purpose buckets.

Permissions

To add a tag to a bucket, you must have the following permission:

- `s3:TagResource`

Troubleshooting errors

If you encounter an error when attempting to add a tag to a bucket, you can do the following:

- Verify that you have the required Permissions to add a tag to a bucket.
- If you attempted to add a tag key that starts with the AWS reserved prefix `aws:`, change the tag key and try again.

Steps

You can add tags to buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To add tags to a bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and choose **Add new Tag**.
6. This opens the **Add Tags** page. You can enter up to 50 tag key value pairs.

7. If you add a new tag with the same key name as an existing tag, the value of the new tag overrides the value of the existing tag.
8. You can also edit the values of existing tags on this page.
9. After you have added the tag(s), choose **Save changes**.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to add tags to a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *user input placeholders* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;
import software.amazon.awssdk.services.s3control.model.TagResourceResponse;

public class TagResourceExample {
    public static void tagResourceExample() {
        S3ControlClient s3Control =
 S3ControlClient.builder().region(Region.US_WEST_2).build();

        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                .resourceArn("arn:aws::s3:::bucket/my-bucket")
                .accountId("111122223333")
                .tags(Tag.builder().key("MyTagKey").value("MyTagValue").build())
                .build();

        TagResourceResponse response = s3Control.tagResource(tagResourceRequest);
        System.out.println("Status code (should be 204):");
        System.out.println(response.sdkHttpResponse().statusCode());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for adding tags to a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- TagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to add tags to a general purpose bucket by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws s3control tag-resource --resource-arn arn:aws:s3:::amzn-s3-demo-bucket --region us-east-2 --account-id 444455556666 --tags '[{"Key":"mykey","Value":"myvalue"}]'
```

Viewing bucket tags

You can view or list tags applied to S3 buckets. For more information about tags, see Using tags with S3 general purpose buckets.

Permissions

To view tags applied to a bucket, you must have the following permission:

- `s3:ListTagsForResource`

Troubleshooting errors

If you encounter an error when attempting to list or view the tags of a bucket, you can do the following:

- Verify that you have the required Permissions to view or list the tags of the bucket.

Steps

You can view tags applied to buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To view tags applied to a bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section to view all of the tags applied to the general purpose bucket.
6. The **Tags** section shows the **User-defined tags** by default. You can select the **AWS-generated tags** tab to view tags applied to your bucket by AWS services.

Using the AWS SDKs

This section provides an example of how to view tags applied to a general purpose bucket by using the AWS SDKs.

SDK for Java 2.x

This example shows you how to view tags applied to a general purpose bucket by using the AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResourceExample {
    public static void listTagsForResourceExample() {
        S3ControlClient s3Control =
 S3ControlClient.builder().region(Region.US_WEST_2).build();

        ListTagsForResourceRequest listTagsForResourceRequest =
 ListTagsForResourceRequest.builder()
                .resourceArn("arn:aws::s3:::bucket/my-bucket")
                .accountId("111122223333")
                .build();

        ListTagsForResourceResponse response =
 s3Control.listTagsForResource(listTagsForResourceRequest);
```

```
        System.out.println("Tags on my resource:");
        System.out.println(response.toString());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for viewing the tags applied to a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- ListTagsforResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to view tags applied to a bucket. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn arn:aws::s3:us-east-1:444455556666:bucket/prefix--use1-az4--x-s3 \
```

Response - tags present:

```
{
  "Tags": [
      {
          "Key": "MyKey1",
          "Value": "MyValue1"
      },
      {
          "Key": "MyKey2",
          "Value": "MyValue2"
      },
      {
          "Key": "MyKey3",
          "Value": "MyValue3"
```

```
      }
  ]
}
```

Response - no tags present:

```
{
  "Tags": []
}
```

Deleting a tag from a bucket

You can remove tags from S3 buckets. An AWS tag is a key-value pair that holds metadata about resources, in this case Amazon S3 buckets. For more information about tags, see Using tags with S3 general purpose buckets.

> **Note**
>
> If you delete a tag and later learn that it was being used to track costs or for access control, you can add the tag back to the bucket.

Permissions

To delete a tag from a bucket, you must have the following permission:

- `s3:UntagResource`

Troubleshooting errors

If you encounter an error when attempting to delete a tag from a bucket, you can do the following:

- Verify that you have the required Permissions to delete a tag from a bucket.

Steps

You can delete tags from buckets by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To delete tags from a bucket using the Amazon S3 console:

1. Sign in to Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **buckets**.
3. Choose the bucket name.
4. Choose the **Properties** tab.
5. Scroll to the **Tags** section and select the checkbox next to the tag or tags that you would like to delete.
6. Choose **Delete**.
7. The **Delete user-defined tags** pop-up appears and asks you to confirm the deletion of the tag or tags you selected.
8. Choose **Delete** to confirm.

Using the AWS SDKs

SDK for Java 2.x

This example shows you how to delete tags from a general purpose bucket by using the AWS SDK for Java 2.x. To use the command replace the *`user input placeholders`* with your own information.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;
import software.amazon.awssdk.services.s3control.model.UntagResourceResponse;

public class UntagResourceExample {
    public static void untagResourceExample() {
        S3ControlClient s3Control =
 S3ControlClient.builder().region(Region.US_WEST_2).build();

        UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
                .resourceArn("arn:aws::s3:::bucket/my-bucket")
                .accountId("111122223333")
                .tagKeys("myTagKey")
                .build();
```

```
        UntagResourceResponse response =
 s3Control.untagResource(untagResourceRequest);
        System.out.println("Status code (should be 204):");
        System.out.println(response.sdkHttpResponse().statusCode());
    }
}
```

Using the REST API

For information about the Amazon S3 REST API support for deleting tags from a general purpose bucket, see the following section in the *Amazon Simple Storage Service API Reference*:

- UnTagResource

Using the AWS CLI

To install the AWS CLI, see Installing the AWS CLI in the *AWS Command Line Interface User Guide*.

The following CLI example shows you how to delete tags from a general purpose bucket by using the AWS CLI. To use the command replace the *`user input placeholders`* with your own information.

Request:

```
aws s3control untag-resource \
--resource-arn arn:aws::s3:::amzn-s3-demo-bucket --region us-east-2 --account-
id 111122223333 \
--tag-keys "tagkey1" "tagkey2"
```

Quotas

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Amazon S3 quotas include number of general purpose buckets, directory buckets, access points and more. You can request an increase for some quotas, but not all quotas can be increased. These increases are not granted immediately, so it may take a couple of days for your increase to become effective.

For a list of Amazon S3 quotas and their default values see, Amazon S3 quotas in the *AWS General Reference*.

Quota increases

To request a quota increase

You can request a quota increase by using one of following options:

- From the AWS Management Console: Open the Service Quotas console. In the navigation pane, choose **AWS services**. Select **Amazon S3**, select a quota, and follow the directions to request a quota increase. For instructions, see Requesting a quota increase in the *Service Quotas User Guide*.
- From the AWS CLI: Use the request-service-quota-increase AWS CLI command. For instructions, see Requesting a quota increase in the *Service Quotas User Guide*.

Reference

In addition to the Amazon S3 console, you can work with Amazon S3 programmatically using the Amazon S3 REST APIs, AWS SDKs, or AWS Command Line Interface (AWS CLI).

- Amazon Simple Storage Service API Reference

Document history

- **Current API version:** 2006-03-01

The following table describes the important changes in each release of the *Amazon Simple Storage Service API Reference* and the *Amazon S3 User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
S3 Tables now supports migrating existing data to tables	You can now migrate existing Parquet data from AWS Glue Data Catalog Hive tables in Amazon S3 general purpose buckets into S3 Tables as query-ready Apache Iceberg tables, without provisioning compute. For more informati on, see Migrating tables to S3 Tables.	November 4, 2026
S3 Tables increases the default table bucket quota	The default quota for the number of Amazon S3 table buckets you can create per AWS Region in an account increased from 10 to 100. For more information, see S3 Tables Regions, endpoints, and service quotas.	September 30, 2026
Amazon S3 Express One Zone adds new AWS managed policies	Amazon S3 Express One Zone added new AWS-managed policies called `AmazonS3ExpressFul lAccess` and `AmazonS3E xpressReadOnlyAcce`	April 3, 2026

	ss . For more information, see AWS managed policies for Amazon S3 Express One Zone.	
S3 Tables updated the AmazonS3TablesFull Access AWS managed policy for S3 Tables	S3 Tables updated the AWS-managed policy called AmazonS3TablesFull Access . This policy now grants permissions to pass a role to the S3 Tables Replicati on service. For more informati on, see AWS managed policies for S3 Tables.	December 2, 2025
S3 Tables now supports automatic replication	S3 Tables now supports automatic replication of Apache Iceberg tables stored in Amazon S3 table buckets. For more information, see Replicating S3 tables.	December 2, 2025
S3 Tables now supports Intelligent-Tiering access tiers	S3 Tables now supports Intelligent-Tiering access tiers which continuously monitors access patterns and automatically moves table data between access tiers. For more information, see Cost optimization for tables with Intelligent-Tiering.	December 2, 2025

Large object support	Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 TB to 50 TB. For uploading these larger objects, you must implement the Multipart Upload REST API to upload objects in parts, and when downloading these objects, use concurrent `GetObject` requests, as single GET requests are limited to 5 TB. For more information, see Uploading objects and Downloading objects.	December 2, 2025
Amazon S3 Metadata is now available in 22 additional AWS Regions	For more information, see Amazon S3 Metadata AWS Regions.	November 26, 2025

Amazon S3 console adds integration with Amazon SageMaker Unified Studio for Amazon S3 Tables	You can now query your data in S3 Tables by using a rich SQL editor provided by Amazon SageMaker Unified Studio, accessible directly from the S3 console with a few clicks. Within SageMaker Unified Studio, you can write SQL queries or ask questions using natural language, and a SQL query is automatic ally generated based on the context of your data. Then, you can schedule queries to automate data processing. For more information, see Using S3 Tables with SageMaker Unified Studio.	November 21, 2025

Amazon S3 now supports tags on S3 Tables for attribute-based access control (ABAC) and cost allocation	Amazon S3 now supports tagging S3 Tables for attribute-based access control (ABAC) and cost allocation. You can use tags for ABAC to automatically manage permissions for users and roles accessing table buckets and tables, eliminating frequent IAM or S3 Tables resource-based policy updates and simplifying how you govern access at scale. You can also add tags to individua l tables to track and organize AWS costs using AWS Billing and Cost Management. Amazon S3 supports tags on S3 Tables in all AWS Regions where S3 Tables is available . You can get started with tagging by using the AWS Management Console, SDK, API, or CLI. For more informati on, see Tagging for cost allocation or attribute-based access control (ABAC).	November 6, 2025
Amazon S3 Metadata is now available in three additional AWS Regions	Amazon S3 Metadata is now available in three additiona l AWS Regions: Europe (Frankfurt), Europe (Ireland) , and Asia Pacific (Tokyo). For more information, see Amazon S3 Metadata AWS Regions.	October 22, 2025

S3 Object Lambda will no longer be open to new customers starting on November 7th, 2025	S3 Object Lambda will no longer be open to new customers starting November 7, 2025. If you would like to use S3 Object Lambda, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon S3 Object Lambda availability change.	October 7, 2025

Amazon S3 now supports conditional deletes in general purpose buckets	Amazon S3 now supports conditional deletes in general purpose buckets. Conditional deletes verify that an object is unchanged before deleting it. Using conditional deletes helps you to prevent accidental deletions in high-concurrency, multiple-writer scenarios. You can now perform conditional deletes using the HTTP `if-match` header with an ETag value. Amazon S3 only allows your delete request to succeed if the Etag provided matches that of the object. Additionally, you can use the `s3:if-match` condition key in your S3 bucket policies to enforce conditional delete operations. For example, you can require clients to use the HTTP `if-match` header in both `DeleteObject` and `DeleteObjects` API operation requests, helping you to minimize the risk of accidentally deleting objects in your bucket. For more information, see How to perform conditional deletes.	September 16, 2025

Amazon S3 Batch Operations now supports managing objects within an S3 bucket, prefix, suffix, or more, in a single step in the Amazon S3 console	When creating an S3 Batch Operations job, you can specify the objects on which to perform the operation. With this feature, you can instead specify an entire bucket, prefix, suffix, creation date, or storage class. Batch Operations will then apply the operation to all the matching objects and notify you when the job is finished. For more information, see Performing object operations in bulk with Batch Operations.	September 15, 2025
Amazon S3 now supports Access Points tags for attribute-based access control (ABAC)	Amazon S3 now supports tagging Access Points for both general purpose and directory buckets. Add tags to access points and use attribute-based access control (ABAC) to scale access. You can get started with tagging access points using the AWS Management Console, S3 REST API, AWS CLI, or the AWS SDK. To learn more about using tags for ABAC, see Using tags for attribute-based access control (ABAC).	July 31, 2025

Amazon S3 Vectors (Preview)	Amazon S3 Vectors delivers purpose-built, cost-optimized vector storage for your semantic search and AI applications. S3 Vectors introduces a new bucket type, the vector bucket, which is optimized for durable, low-cost vector storage. For more information, see Working with S3 Vectors and vector buckets.	July 15, 2025

Amazon S3 Metadata now supports existing objects	Amazon S3 Metadata creates and manages metadata that provides information about datasets stored in S3, so you can more easily discover and use your S3 data. Previously, S3 Metadata supported new and updated objects. Now, S3 Metadata also creates and manages metadata for all your existing S3 data. S3 Metadata now creates and maintains two Apache Iceberg tables that give you a qu eryable and continuously updated view of the metadata associated with the objects in a general purpose bucket. A journal table records changes made to your data in near real time, helping you to identify new data uploaded to your bucket, track recently deleted objects, monitor S3 Lifecycle transitions, and more. A new live inventory table provides and maintains an up-to-dat e view of all objects in your bucket. Both S3 Metadata tables are stored in an AWS managed Iceberg table bucket in your account, and can be queried using standard SQL through AWS analytics services, such as Amazon Athena or Amazon EMR, and	July 15, 2025

	open source tooling, such as DuckDB and PyIceberg. For more information, see Accelerating data discovery with S3 Metadata.	
Amazon S3 Express One Zone now supports tags for cost allocation and attribute-based access control	Amazon S3 Express One Zone, a high performance S3 storage class, now supports tags for cost allocation and attribute-based access control (ABAC). You can add tags to S3 directory buckets to track and organize AWS costs using AWS Billing and Cost Management. Additionally, with ABAC support, you can scale access control to your directory buckets by using tags. S3 Express One Zone supports tags on directory buckets in all AWS Regions where the storage class is available. You can get started with tagging using the AWS Management Console, S3 REST API, AWS CLI, or the AWS SDK. To learn more about using tags to simplify cost allocation or ABAC, see Using tags with S3 directory buckets.	July 2, 2025

S3 Tables now supports CloudTrail events for maintenance operations	S3 Tables now supports AWS CloudTrail events for maintenance operation s. You can now track and audit maintenance activities performed on your S3 Tables resources through CloudTrai l logs. For more information, see S3 Tables maintenance.	June 30, 2025
Access points now supports attaching to an FSx for OpenZFS volume	You can create and attach an access point to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data. Your data continues to reside on the Amazon FSx file system and continues to be directly accessible for your existing workloads. For more information, see Managing access to shared datasets with access points.	June 25, 2025
S3 Tables now supports new compaction strategies for tables	S3 Tables now supports multiple compaction strategie s to optimize query perform ance based on different data access patterns. The new strategies include Sort and Z-order. For more information, see Compaction Strategies for tables.	June 18, 2025

Enhanced access denied error messages for same-organization requests	Amazon S3 now includes additional context in access denied (HTTP `403 Forbidden`) errors for requests made to resources within the same organization in AWS Organizations. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-organization requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3..	June 16, 2025

S3 Tables adds new AWS managed policy for S3 Tables	S3 Tables added a new AWS-managed policy called `AmazonS3TablesLakeFormationServiceRole`. This policy grants permissions that allows the Lake Formation service role access to Amazon S3 tables and table buckets. For more information, see AWS managed policies for S3 Tables.	May 19, 2025
S3 Tables now supports SSE-KMS using customer managed keys	S3 Tables now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You can apply SSE-KMS encryption at the table bucket and table level. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS) in table buckets.	April 16, 2025

Access points for directory buckets are available in AWS Local Zones	Directory buckets now support access points to simplify managing data access at scale for shared datasets in Amazon S3. With this new feature, you can create hundreds of access points per bucket, each with a distinct name and permissions customized for each applicati on. For more information, see Managing access to shared datasets in directory buckets with access points.	March 31, 2025

S3 table bucket integration with Amazon SageMaker Lakehouse is now generally available	You can integrate S3 table buckets with Amazon SageMaker Lakehouse to access tables from AWS analytics services, such as Amazon Athena, Amazon Redshift, and Quick. Amazon SageMaker Lakehouse unifies your data across Amazon S3 data lakes and Amazon Redshift data warehouses, so you can build analytics, machine learning (ML), and generative AI applications on a single copy of data. The integration populates the AWS Glue Data Catalog with your table resources , and federates access to these resources with AWS Lake Formation. The integration enables fine-grained access control through Lake Formation to provide additional security. For more information about integrating, see Using Amazon S3 Tables with AWS analytics services. If you set up the integration with the preview release, you can continue to use your current integration. However, the updated integration process provides performance improvements, so we recommend migrating	March 13, 2025

	. To migrate to the updated integration, see Migrating to the updated integration process.	
S3 Tables create table and query table support added to the Amazon S3 console	S3 Tables now support create table and query table operations directly from the Amazon S3 console by using Amazon Athena. With this new feature, you can now create a table, populate it with data, and query it with just a few steps in the Amazon S3 console. For more information, see Creating an Amazon S3 table and Querying Amazon S3 tables with Athena.	March 13, 2025
S3 Tables adds support for adding schemas when creating tables	You can now use the S3 Tables `CreateTable` API operation to create tables with schemas by adding an optional metadata flag. For more information, see Creating an Amazon S3 table.	January 30, 2025

S3 Metadata is now generally available	Amazon S3 Metadata is now generally available. S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see Accelerating data discovery with S3 Metadata.	January 27, 2025
AWS managed policies – New policies	S3 Tables added two new AWS managed policies.	December 6, 2024

S3 Tables	Amazon S3 Tables provide S3 storage that's optimized for analytics workloads, with features that improve query performance, reduce storage costs for tables, and simplify the operation of data lakes at scale. S3 Tables introduces a new bucket type: table buckets, which are purpose-built for storing Apache Iceberg tables as subresources. Table buckets provide higher transactions per second (TPS) and better query throughput compared to self-managed tables in S3 general purpose buckets. You can automatically integrate your table buckets with AWS analytics services, such as Athena, Amazon Redshift Quick, and more. For more information, see Working with Amazon S3 Tables and table buckets.	December 3, 2024

S3 Metadata preview	Amazon S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see Accelerating data discovery with S3 Metadata.	December 3, 2024
Storage Browser for S3	Storage Browser for S3 is an open source component that you can add to your web applications to provide your end users with a simple interface for data stored in S3. For more information, see Storage Browser for S3.	December 1, 2024

New Amazon S3 checksum algorithm and improved checksum integrity features	Amazon S3 adds the `CRC-64NVME` checksum algorithm and improved checksum integrity features. For more information, see Checking object integrity in Amazon S3.	December 1, 2024
Data residency workloads	In Dedicated Local Zones, you can create S3 directory buckets to store data for your data residency and isolation use cases. For more information, see Data residency workloads.	December 1, 2024
New condition keys to enforce conditional writes	Amazon S3 adds new condition keys `s3:if-match` and `s3:if-none-match` to use in bucket policies to force clients to use the `If-None-Match` or `If-Match` HTTP header. For more information, see Enforce conditional writes on Amazon S3 buckets.	November 25, 2024

New HTTP header for conditional writes to check if the object has changed	Amazon S3 adds the `If-Match` HTTP header to check an object's entity tag (ETag) before writing an object for some API operations. With this header, Amazon S3 compares the provided ETag value with the ETag value of the object in S3. If the ETag values don't match, the operation fails. For more information, see How to prevent object overwrites with conditional writes.	November 25, 2024
Amazon Redshift now integrates with S3 Access Grants	Amazon Redshift customers can now use S3 Access Grants to scale and manage permissions for their S3 data. This allows Amazon Redshift customers to scale S3 permissions for corporate identities by using AWS IAM Identity Center as well as for IAM users and groups. For more information, see Amazon Redshift integration with Amazon S3 Access Grants.	November 15, 2024

AWS Organizations member accounts can now regain access to accidentally locked Amazon S3 buckets	AWS Organizations member accounts can now use a simple process through AWS Identity and Access Management (IAM) to regain access to accidentally locked Amazon S3 buckets. For more information, see Perform a privileged task on an AWS Organizations member account in the *AWS Identity and Access Management User Guide*.	November 14, 2024
Resource control policies (RCPs), a new type of authorization policy in AWS Organizations is also available for Amazon S3 buckets	Resource control policies (RCPs), a new authorization policy managed in AWS Organizations can be used to set the maximum available permissions on Amazon S3 buckets within your entire organization. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.	November 13, 2024
Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets	Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets. To view your bucket utilization or request an increase, visit the Service Quotas console.	September 30, 2024

New default minimum object size transition behavior for Amazon S3 Lifecycle configurations	Amazon S3 now applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitioned to any storage class. To learn how to override this behavior, see Allowing objects smaller than 128 KB to be transitioned.	September 24, 2024
Directory buckets now support SSE-KMS using customer managed keys.	Directory buckets now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You have more options to encrypt and manage the security of your data in directory buckets. For more information, see Data protection and encryption in directory buckets.	September 17, 2024

S3 Access Grants supports an API action that lists the caller's access grants	IAM identities and IAM Identity Center corporate directory identities can now use the `ListCallerAccessGrants` API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or corporate directory identity can access through S3 Access Grants, within a particular AWS account. For more information, see List the caller's access grants.	September 5, 2024

Enhanced access denied error messages for same-account requests	Amazon S3 now includes additional context in access denied (HTTP `403 Forbidden`) errors for requests made to resources within the same AWS account. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3..	August 21, 2024

Amazon S3 supports using conditional writes for `PutObject` and `CompleteMultipartUpload`	You can check for the existence of an object in your bucket before creating it using a conditional write on upload operations. This can prevent overwrites of existing data. Conditional writes will validate there is no existing object with the same key name already in your bucket. For more information, see Conditional requests.	August 20, 2024
Amazon S3 no longer charges for several HTTP error codes	Amazon S3 has completed a change so unauthorized requests that customers did not initiate are free of charge. For more information, see Billing for Amazon S3 error responses.	August 19, 2024
Amazon S3 Select is no longer available to new customers	Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. Learn more.	July 25, 2024

Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key	Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key to control whether users can include optional metadata fields in their reports. For more information, see Control S3 Inventory report configuration creation.	February 20, 2024
IPv6 support for S3 on Outposts	You can now access S3 on Outposts buckets using IPv6 through S3 on Outposts dual-stack endpoints. IPv6 support for S3 on Outposts allows you to manage your S3 on Outposts buckets and control plane resources over IPv6 networks.	January 16, 2024
New high-performance, single-zone Amazon S3 storage class – S3 Express One Zone	Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. For more information, see S3 Express One Zone.	November 28, 2023
Mountpoint for Amazon S3 adds support for S3 Express One Zone	You can now mount S3 Express One Zone directory buckets with Mountpoint.	November 28, 2023

Lambda invocation schema version	Amazon S3 Batch Operations introduces a new Lambda invocation schema version for use with Batch Operations jobs that act on directory buckets. For more information, see Using Lambda and Amazon S3 batch operations with directory buckets.	November 28, 2023
Import action for directory buckets	Amazon S3 introduces the import action. Import is a streamlined method for creating Amazon S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For more information, see Importing objects into a directory bucket.	November 28, 2023
Manage S3 access with S3 Access Grants	Amazon S3 Access Grants enables you to manage data permissions at scale for AWS Identity and Access Management (IAM) principals in addition to directory identities from corporate directories such as Azure AD. You can now enforce least-privilege S3 permissions and easily scale those permissions based on your business needs. For more information, see Managing access with S3 Access Grants.	November 26, 2023

Mountpoint for Amazon S3 adds caching feature	With Mountpoint, you can now configure caching for repeatedly accessed data.	November 22, 2023
Enhanced Amazon S3 Batch Operations manifest generation	You can now direct Amazon S3 Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see Creating an Amazon S3 Batch Operations job.	November 22, 2023
Existing Amazon S3 buckets can now add Object Lock configurations	You can now enable Object Lock on existing Amazon S3 bucket. You may set legal holds and retention periods for new or existing buckets. For more information, see Using Object Lock.	November 20, 2023
S3 Storage Lens request metrics for prefixes	S3 Storage Lens introduces request metrics for prefixes within an Amazon S3 bucket. For more information, see Metrics categories.	November 17, 2023

Amazon S3 Storage Lens groups	S3 Storage Lens introduces Storage Lens groups, a custom defined filter for objects based on object metadata. For more information, see Working with Amazon S3 Storage Lens groups.	November 15, 2023
New IAM policy	S3 on Outposts introduces `AWSServiceRoleForS3nOutposts`, a service-linked role to help manage network resources for you. For more information, see Using service-linked roles for S3 on Outposts.	October 3, 2023
Amazon S3 provides the `Last-Modified` time for delete markers	Amazon S3 provides the `Last-Modified` time of delete markers in the response headers of S3 `Head` and `Get` API operations. For more information, see Working with delete markers.	September 27, 2023
Amazon S3 update to AWS managed policy	Amazon S3 added `s3:Describe*` permissions to `AmazonS3ReadOnlyAccess`. For more information, see AWS managed policies for Amazon S3.	August 11, 2023

Improved start times for Standard restore requests made through S3 Batch Operations	Standard retrievals for restore requests that are made through S3 Batch Operations now can start within minutes. For more information, see Archive Retrieval Options.	August 9, 2023
Added Mountpoint, a high-throughput client for mounting an Amazon S3 bucket as a local file system.	With Mountpoint, your applications can access objects stored in Amazon S3 through file operations, g iving your applications access to the elastic storage and throughput of Amazon S3 t hrough a file interface.	August 9, 2023
Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)	Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) ap plies two layers of encryptio n to objects when they are uploaded to Amazon S3. For more information, see Using dual-layer server-sid e encryption with AWS KMS keys.	June 13, 2023

Amazon S3 enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new buckets.	Amazon S3 now automatically enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new S3 buckets in all AWS Regions. For more information, see Blocking public access to your Amazon S3 storage and Controlling ownership of objects and disabling ACLs for your bucket.	April 27, 2023
S3 Replication Operations Failed metric	Amazon S3 adds new Amazon CloudWatch metric to monitor S3 Replication failures. For more information, see Monitoring progress with replication metrics.	April 5, 2023
Private DNS	AWS PrivateLink for Amazon S3 now supports Private DNS. For more information, see Private DNS.	March 14, 2023
Cross-account access points support in the Amazon S3 console	Amazon S3 now supports creating cross-account access points with the Amazon S3 console. For more information, see Creating access points.	March 14, 2023

Amazon S3 on Outposts supports S3 Replication on Outposts	With local S3 Replication, you can automatically replicate objects to a single Outposts destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Outposts or within the same Outposts as the source bucket. For more information, see Replicating objects for S3 on Outposts.	March 14, 2023
Amazon S3 Object Lambda Access Point alias	When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For more information, see How to use a bucket-style alias for your Object Lambda Access Point.	March 14, 2023
Amazon S3 Multi-Region Access Points cross-account support	Amazon S3 now supports creating cross-account Multi-Region Access Points with the Amazon S3 console. For more information, see Creating Multi-Region Access Points.	March 14, 2023

Cross-account access points	Amazon S3 supports creating cross-account access points. You can create a cross-account access point by using the AWS Command Line Interface (AWS CLI) or the REST API `CreateAccessPoint` operation. For more information, see Creating access points.	November 30, 2022
Amazon S3 supports failover controls for Amazon S3 Multi-Region Access Points	Amazon S3 introduces failover control for Multi-Region Access Points. These controls let you shift S3 data access request traffic routed through an Amazon S3 Multi-Region Access Point to an alternate AWS Region within minutes to test and build highly available applications. For more information, see Amazon S3 Multi-Region Access Point failover controls.	November 28, 2022
Amazon S3 Storage Lens increases organization-wide visibility with 34 new metrics	S3 Storage Lens introduces 34 additional metrics to uncover deeper cost-optimization opportunities, identify data-protection best practices, and improve the performance of application workflows. For more information, see S3 Storage Lens metrics.	November 17, 2022

Amazon S3 supports higher restore request rates for S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive	Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.	November 15, 2022
Amazon S3 on Outposts supports additional S3 Lifecycle actions and filters	S3 on Outposts supports additional S3 Lifecycle rules to optimize capacity mana gement. You can expire objects as they age or are replaced with newer version s. You can create a lifecycle rule for a whole bucket or a subset of objects in a bucket by filtering with prefixes, object tags, or object size. For more information, see Creating and managing a lifecycle configuration.	November 2, 2022
S3 Replication support for SSE-C objects	You can replicate objects that are created using server-side encryption with customer -provided keys. For more information about replicati ng encrypted objects, see Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS).	October 24, 2022

Amazon S3 on Outposts supports access point aliases	With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Every time you create an access point for a bucket, S3 on Outposts automatically generates an access point alias. You can use this access point alias instead of an access point ARN for any data plane operation. For more information, see Using a bucket-style alias for your S3 on Outposts bucket access point.	October 21, 2022
S3 Object Lambda supports the `HeadObject`, `ListObjects`, and `ListObjectsV2` operations	You can use custom code to modify the data returned by standard S3 `GET`, `LIST`, or `HEAD` requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see Transforming objects with S3 Object Lambda.	October 4, 2022

Amazon S3 on Outposts supports S3 Versioning	When enabled, S3 Versioning saves multiple distinct copies of an object in the same bucket. You can use S3 Versioning to preserve, retrieve, and restore every version of every object stored in your Outposts buckets. S3 Versioning helps you recover from unintended user actions and application failures. For more information, see Managing S3 Versioning for your S3 on Outposts bucket.	September 21, 2022
AWS Backup for Amazon S3	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information, see Using AWS Backup for Amazon S3.	February 18, 2022

Use S3 Batch Replication to replicate existing objects	With S3 Batch Replication, you can replicate objects that existed before a replication configuration was in place. Replicating existing objects is done through the use of a Batch Operations job. S3 Batch Replication differs from live replication, which continuously and automatic ally copies new objects across Amazon S3 buckets. For more information, see Replicating existing objects with S3 Batch Replication.	February 8, 2022
Rename of S3 Glacier Flexible Retrieval	The Glacier storage class has been renamed to S3 Glacier Flexible Retrieval. This change does not impact the API.	November 30, 2021

New S3 Object Ownership setting to disable ACLs	You can apply the bucket owner enforced setting for Object Ownership to disable ACLs for your bucket and the objects in it and take ownership of every object in your bucket. The bucket owner enforced setting simplifies access management for data stored in Amazon S3. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.	November 30, 2021
New S3 Intelligent-Tiering storage class	S3 Intelligent-Tiering Archive Instant Access is an additional storage class under S3 Intelligent-Tiering. For more information, see How S3 Intelligent-Tiering works.	November 30, 2021
New S3 Glacier Instant Retrieval storage class	You can now place objects in the S3 Glacier Instant Retrieval storage class. For more information about this storage class, see Using Amazon S3 storage classes.	November 30, 2021

AWS Backup for Amazon S3 Preview	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more informati on, see Using AWS Backup for Amazon S3.	November 30, 2021
AWS Identity and Access Management Access Analyzer for Amazon S3	IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. To learn more about validatin g policies using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*.	November 30, 2021
New event types	New event types added to Amazon S3 Event Notificat ions, see Amazon S3 Event Notifications.	November 29, 2021
Enable Amazon EventBridge on buckets	You can enable EventBrid ge on Amazon S3 buckets to send events to Amazon EventBridge, see Using EventBridge.	November 29, 2021
New S3 Lifecycle filters	You can create lifecycle rules based on object size or specify how many noncurre nt object versions to keep. For more information, see Examples of S3 Lifecycle configuration.	November 23, 2021

Publish Amazon S3 Storage Lens metrics to Amazon CloudWatch	You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, like alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, the CloudWatch APIs enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information, see the Monitor S3 Storage Lens metrics in CloudWatch.	November 22, 2021
Multi-Region Access Points	You can use Multi-Region Access Points to create a global endpoint that applications can use to fulfill requests from Amazon S3 buckets located in multiple AWS Regions. You can use this Multi-Region Access Point to route data to a bucket with the lowest latency. For more information about Multi-Region Access Points and how to use them, see Multi-Region Access Point in Amazon S3.	September 2, 2021

Amazon S3 on Outposts adds direct local access for applications	Run your applications outside the AWS Outposts virtual private cloud (VPC) and access your S3 on Outposts data. You can also access S3 on Outposts objects directly from your on-premises network. For more information about configuring S3 on Outposts endpoints using customer-owned IP (CoIP) addresses and accessing your objects by creating a local gateway from your on-premises network, see Accessing Amazon S3 on Outposts using VPC-only access points.	July 29, 2021
Amazon S3 access point alias	When you create an access point, Amazon S3 automatically generates an alias that you can use instead of a bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for any access point data plane operation. For more information, see Using a bucket-style alias for your access point.	July 26, 2021

Amazon S3 Inventory and S3 Batch Operations support S3 Bucket Key status	Amazon S3 Inventory and Batch Operations support identifying and copying existing objects with S3 Bucket Keys. S3 Bucket Keys accelerate the reduction of server-side encryption costs for existing objects. For more information, see Amazon S3 Inventory and Batch Operations Copy object.	June 3, 2021
Amazon S3 Storage Lens metrics account snapshot	The S3 Storage Lens account snapshot displays your total storage, object count, and average object size on the S3 console home (**Buckets**) page by summarizing metrics from your default dashboard. For more information, see S3 Storage Lens metrics account snapshot.	May 5, 2021
Increased Amazon S3 on Outposts endpoint support	S3 on Outposts now supports up to 100 endpoints per Outpost. For more information, see S3 on Outposts network restrictions.	April 29, 2021

Amazon S3 on Outposts event notifications in Amazon CloudWatch Events	You can use CloudWatch Events to create a rule to capture any S3 on Outposts API event and get notified through all supported CloudWatch targets. For more information, see Receiving S3 on Outposts event notifications using CloudWatch Events.	April 19, 2021
S3 Object Lambda	With S3 Object Lambda, you can add your own code to Amazon S3 GET requests to modify and process data as it is returned to an application. You can use custom code to modify the data returned by standard S3 GET requests to f ilter rows, dynamically resize images, redact confidential data, and more. For more information, see Transform ing objects.	March 18, 2021

AWS PrivateLink	With AWS PrivateLink for Amazon S3, you can connect directly to S3 by using an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. Interface endpoints are directly accessible from applications that are on premises or in a different AWS Region. For more information, see AWS PrivateLink for Amazon S3.	February 2, 2021
Managing Amazon S3 on Outposts capacity with AWS CloudTrail	S3 on Outposts management events are available through CloudTrail logs. For more information, see Managing S3 on Outposts capacity with CloudTrail.	December 21, 2020
Strong consistency	Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your S3 bucket in all AWS Regions. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists, Amazon S3 Object Tags, and object metadata (for example, HEAD object) are strongly consistent. For more information, see Amazon S3 data consistency model.	December 1, 2020

Amazon S3 replica modification sync	Amazon S3 replica modification sync keeps object metadata, such as tags, ACLs, and Object Lock settings, in sync between source objects and replicas. When this feature is enabled, Amazon S3 replicates metadata changes made to either the source object or the replica copies. For more information, see Replicating metadata changes with replica modification sync.	December 1, 2020
Amazon S3 Bucket Keys	Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (SSE-KMS). This new bucket-level key for server-side encryption can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS by using S3 Bucket Keys.	December 1, 2020

Amazon S3 Storage Lens	S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics report in CSV or Parquet format to a general purpose S3 bucket or export the metrics directly to an AWS-managed S3 table bucket. For more information, see Assessing your storage activity and usage with S3 Storage Lens.	November 18, 2020

Tracing S3 requests using AWS X-Ray	Amazon S3 integrates with X-Ray to propagate the trace context and give you one request chain with upstream and downstream nodes. For more information, see Tracing requests using X-Ray.	November 16, 2020
S3 Replication metrics	S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. For more information, see Replication metrics and Amazon S3 event notifications.	November 9, 2020
S3 Intelligent-Tiering Archive Access and Deep Archive Access	S3 Intelligent-Tiering Archive Access and Deep Archive Access are additional storage tiers under S3 Intelligent-Tiering. For more information, see Storage class for automatically optimizing frequently and infrequently accessed objects .	November 9, 2020
Delete marker replication	With delete marker replication, you can ensure that delete markers are copied to your destination buckets for your replication rules. For more information, see Using delete marker replication.	November 9, 2020

S3 Object Ownership	Object Ownership is an S3 bucket setting that you can use to control ownership of new objects that are uploaded to your buckets. For more information, see Using S3 Object Ownership.	October 2, 2020
Amazon S3 on Outposts	With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and easily store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API. For more information, see Using Amazon S3 on Outposts.	September 30, 2020
Bucket owner condition	You can use the Amazon S3 bucket owner condition to ensure that the buckets you use in your S3 operations belong to the AWS accounts that you expect. For more information, see Bucket owner condition.	September 11, 2020

S3 Batch Operations support for Object Lock Retention	You can now use Batch Operations with S3 Object Lock to apply retention settings to many Amazon S3 objects at once. For more information, see Setting S3 Object Lock Retention dates with S3 Batch Operations.	May 4, 2020
S3 Batch Operations support for Object Lock Legal Hold	You can now use Batch Operations with S3 Object Lock to add a legal hold to many Amazon S3 objects at once. For more information, see Using S3 Batch Operations for setting S3 Object Lock Legal Hold.	May 4, 2020
Job tags for S3 Batch Operations	You can add tags to your S3 Batch Operations jobs to control and label those jobs. For more information, see Tags for S3 Batch Operations jobs.	March 16, 2020
Amazon S3 access points	Amazon S3 access points simplify managing data access at scale for shared datasets in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations. For more information, see Managing data access with Amazon S3 access points.	December 2, 2019

Access Analyzer for Amazon S3	Access Analyzer for Amazon S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including accounts outside of your organization. For more information, see Using Access Analyzer for Amazon S3.	December 2, 2019
S3 Replication Time Control (S3 RTC)	S3 Replication Time Control (S3 RTC) replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes. For more information, see Replicating objects using S3 Replication Time Control (S3 RTC).	November 20, 2019
Same-Region Replication	You can use Same-Region Replication (SRR) to copy objects across Amazon S3 buckets in the same AWS Region. For information about both Cross-Region Replication (CRR) and Same-Region Replication, see Replication.	September 18, 2019
Cross-Region Replication support for S3 Object Lock	Cross-Region Replication now supports Object Lock. For more information, see What does Amazon S3 Replicate?.	May 28, 2019

S3 Batch Operations	By using S3 Batch Operations, you can perform large-scale Batch Operations on Amazon S3 objects. S3 Batch Operations can run a single operation on lists of objects that you specify. A single job can perform the specified operation on billions of objects containing exabytes of data. For more information, see Performing S3 Batch Operations.	April 30, 2019
Asia Pacific (Hong Kong) Region	Amazon S3 is now available in the Asia Pacific (Hong Kong) Region. For more information about Amazon S3 Regions and endpoints, see Regions and endpoints in the *AWS General Reference*.	April 24, 2019
Added a new field to the server access logs	Amazon S3 added the following new field to the server access logs: Transport Layer Security (TLS) version. For more information, see Server access log format.	March 28, 2019
New archive storage class	Amazon S3 now offers a new archive storage class, S3 Glacier Deep Archive (`DEEP_ARCHIVE`), for storing rarely accessed objects. For more information, see Storage Classes.	March 27, 2019

Added new fields to the server access logs	Amazon S3 added the following new fields to the server access logs: Host Id, Signature Version, Cipher Suite, Authentication Type, and Host Header. For more information, see Server access log format.	March 5, 2019
Support for Parquet-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache Parquet (Parquet) format in addition to the Apache optimized row columnar (ORC) and comma-separated values (CSV) file formats for inventory output files. For more information, see Inventory.	December 4, 2018
S3 Object Lock	Amazon S3 now offers Object Lock functionality that provides Write Once Read Many (WORM) protections for Amazon S3 objects. For more information, see Locking Objects.	November 26, 2018
Restore speed upgrade	Using Amazon S3 restore speed upgrade, you can change the speed of a restoration from the S3 Glacier Flexible Retrieval storage class to a faster speed while the restoration is in progress. For more information, see Restoring Archived Objects.	November 26, 2018

Restore Event Notifications	Amazon S3 Event Notifications now support initiation and completion events when restoring objects from the S3 Glacier Flexible Retrieval storage class. For more information, see Event Notifications.	November 26, 2018

PUT directly to the S3 Glacier Flexible Retrieval storage class	The Amazon S3 PUT operation now supports specifying S3 Glacier Flexible Retrieval as the storage class when creating objects. Previously, you had to transition objects to the S3 Glacier Flexible Retrieval storage class from another Amazon S3 storage class. Also, when using S3 Cross-Region Replication (CRR), you can now specify S3 Glacier Flexible Retrieval as the storage class for replicated objects. For more information about the S3 Glacier Flexible Retrieval storage class, see Storage Classes. For more information about specifying the storage class for replicated objects, Replication Configuration Overview. For more informati on about the direct PUT to S3 Glacier Flexible Retrieval REST API changes, see Document History: PUT directly to S3 Glacier Flexible Retrieval .	November 26, 2018

New storage class	Amazon S3 now offers a new storage class named S3 Intelligent-Tiering (`INTELLIGENT_TIERING`) that is designed for long-lived data with changing or unknown access patterns. For more information, see Storage Classes.	November 26, 2018
Amazon S3 Block Public Access	Amazon S3 now includes the ability to block public access to buckets and objects on a per-bucket or account-wide basis. For more information, see Using Amazon S3 Block Public Access.	November 15, 2018
Filtering enhancements in Cross-Region Replication (CRR) rules	In a CRR rule configuration, you can specify an object filter to choose a subset of objects to apply the rule to. Previously, you could filter only on an object key prefix. In this release, you can filter on an object key prefix, one or more object tags, or both. For more information, see CRR Setup: Replication Configuration Overview.	September 19, 2018

New Amazon S3 Select features	Amazon S3 Select now supports Apache Parquet input, queries on nested JSON objects, and two new Amazon CloudWatch monitoring metrics (`SelectScannedBytes` and `SelectReturnedBytes`).	September 5, 2018
Updates now available over RSS	You can now subscribe to an RSS feed to receive notifications about updates to the *Amazon S3 User Guide*.	June 19, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon S3 User Guide* before June 19, 2018.

Change	Description	Date
Code examples update	Code examples updated: • C#—Updated all of the examples to use the task-based asynchronous pattern. For more information, see Amazon Web Services Asynchronous APIs for .NET in the *AWS SDK for .NET Developer Guide*. Code examples are now compliant with version 3 of the AWS SDK for .NET. • Java—Updated all of the examples to use the client builder model. For more information about the client builder model, see Creating Service Clients. •	April 30, 2018

Change	Description	Date
	PHP—Updated all of the examples to use the AWS SDK for PHP 3.0. For more information about the AWS SDK for PHP 3.0, see AWS SDK for PHP. • Ruby—Updated example code so that the examples work with the AWS SDK for Ruby version 3.	

Amazon S3 now reports S3 Glacier Flexible Retrieval and ONEZONE_IA storage classes to Amazon CloudWatch Logs storage metrics	In addition to reporting actual bytes, these storage metrics include per-object overhead bytes for applicable storage classes (ONEZONE_IA , STANDARD_IA , and S3 Glacier Flexible Retrieval):
	• For ONEZONE_IA and STANDARD_IA storage class objects, Amazon S3 reports objects smaller than 128 KB as 128 KB. For more information, see Understanding and managing Amazon S3 storage classes.
	• For S3 Glacier Flexible Retrieval storage class objects, the storage metrics report the following overheads:
	  • A 32 KB per-object overhead, charged at S3 Glacier Flexible Retrieval storage class pricing
	  • An 8 KB per-object overhead, charged at STANDARD storage class pricing
	  For more information, see Transitioning objects using Amazon S3 Lifecycle.
	For more information about storage metrics, see Monitoring metrics with Amazon CloudWatch.
		April 30, 2018

Change	Description	Date
New storage class	Amazon S3 now offers a new storage class, `STANDARD_IA` (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes.	April 4, 2018
Amazon S3 Select	a>Amazon S3 now supports retrieving object content based on an SQL expression. For more information, see Querying data in place with Amazon S3 Select.	April 4, 2018
Asia Pacific (Osaka-Local) Region	Amazon S3 is now available in the Asia Pacific (Osaka-Local) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*. **Important** You can use the Asia Pacific (Osaka-Local) Region only in conjunction with the Asia Pacific (Tokyo) Region. To request access to Asia Pacific (Osaka-Local) Region, contact your sales representative.	February 12, 2018
Amazon S3 Inventory creation timestamp	Amazon S3 Inventory now includes a timestamp of the date and start time of the creation of the Amazon S3 Inventory report. You can use the timestamp to determine changes in your Amazon S3 storage from the start time of when the inventory report was generated.	January 16, 2018
Europe (Paris) Region	Amazon S3 is now available in the Europe (Paris) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	December 18, 2017

Change	Description	Date
China (Ningxia) Region	Amazon S3 is now available in the China (Ningxia) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	November 29, 2017
Support for ORC-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache optimized row columnar (ORC) format in addition to comma-separated values (CSV) file format for inventory output files. Also, you can now query Amazon S3 inventory using standard SQL by using Amazon Athena, Amazon Redshift Spectrum, and other tools such as Presto, Apache Hive, and Apache Spark. For more information, see Cataloging and analyzing your data with S3 Inventory.	November 17, 2017
Default encryption for S3 buckets	Amazon S3 default encryption provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The objects are encrypted using server-side encryption with either Amazon S3 managed keys (SSE-S3) or AWS managed keys (SSE-KMS). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.	November 06, 2017
Encryption status in Amazon S3 Inventory	Amazon S3 now supports including encryption status in Amazon S3 Inventory so you can see how your objects are encrypted at rest for compliance auditing or other purposes. You can also configure to encrypt Amazon S3 Inventory with server-side encryption (SSE) or SSE-KMS so that all inventory files are encrypted accordingly. For more information, see Cataloging and analyzing your data with S3 Inventory.	November 06, 2017

Change	Description	Date
Cross-Region Replication (CRR) enhancements	Cross-Region Replication now supports the following: • In a cross-account scenario, you can add a CRR configuration to change replica ownership to the AWS account that owns the destination bucket. For more information, see Changing the replica owner. • By default, Amazon S3 does not replicate objects in your source bucket that are created using server-side encryption using keys stored in AWS KMS In your CRR configuration, you can now direct Amazon S3 to replicate these objects. For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).	November 06, 2017
Europe (London) Region	Amazon S3 is now available in the Europe (London) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	December 13, 2016
Canada (Central) Region	Amazon S3 is now available in the Canada (Central) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	December 8, 2016

Change	Description	Date
Object tagging	Amazon S3 now supports object tagging. Object tagging enables you to categorize storage. Object key name prefixes also enable you to categorize storage, object tagging adds another dimension to it. There are added benefits tagging offers. These include: • Object tags enable fine-grained access control of permissions (for example, you could grant an IAM user permissions to read-only objects with specific tags). • Fine-grained control in specifying lifecycle configuration. You can specify tags to select a subset of objects to which lifecycle rule applies. • If you have Cross-Region Replication (CRR) configured, Amazon S3 can replicate the tags. You must grant necessary permission to the IAM role created for Amazon S3 to assume to replicate objects on your behalf. • You can also customize CloudWatch metrics and CloudTrail events to display information by specific tag filters. For more information, see Tagging your objects.	November 29, 2016
Amazon S3 Lifecycle now supports tag-based filters	Amazon S3 now supports tag-based filtering in lifecycle configuration. You can now specify lifecycle rules in which you can specify a key prefix, one or more object tags, or a combination of both to select a subset of objects to which the lifecycle rule applies. For more information, see Managing the lifecycle of objects.	November 29, 2016

Change	Description	Date
CloudWatch request metrics for buckets	Amazon S3 now supports CloudWatch metrics for requests made on buckets. When you enable these metrics for a bucket, the metrics report at 1-minut e intervals. You can also configure which objects in a bucket will report these request metrics. For more information, see Monitoring metrics with Amazon CloudWatch.	November 29, 2016
Amazon S3 Inventory	Amazon S3 now supports storage inventory. Amazon S3 Inventory provides a flat-file output of your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or a shared prefix (that is, objects that have names that begin with a common string). For more information, see Cataloging and analyzing your data with S3 Inventory.	November 29, 2016
Amazon S3 Analytics – Storage Class Analysis	The new Amazon S3 analytics – storage class analysis feature observes data access patterns to help you determine when to transition less frequently accessed `STANDARD` storage to the `STANDARD_IA` (IA, for infrequent access) storage class. After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. This feature also includes a detailed daily analysis of your storage usage at the specified bucket, pr efix, or tag level that you can export to an S3 bucket.	November 29, 2016
New Expedited and Bulk data retrieval s when restoring archived objects from Amazon Glacier	Amazon S3 now supports Expedited and Bulk data retrievals in addition to Standard retrievals when restoring objects archived to Amazon Glacier. For more information, see Restoring an archived object.	November 21, 2016

Change	Description	Date
CloudTrail object logging	CloudTrail supports logging Amazon S3 object level API operations such as `GetObject` , `PutObject` , and `DeleteObject` . You can configure your event selectors to log object level API operations. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.	November 21, 2016
US East (Ohio) Region	Amazon S3 is now available in the US East (Ohio) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	October 17, 2016
IPv6 support for Amazon S3 Transfer Acceleration	Amazon S3 now supports Internet Protocol version 6 (IPv6) for Amazon S3 Transfer Acceleration. You can connect to Amazon S3 over IPv6 by using the new dual-stack for Transfer Acceleration endpoint. For more information, see Getting started with Amazon S3 Transfer Acceleration.	October 6, 2016
IPv6 support	Amazon S3 now supports Internet Protocol version 6 (IPv6). You can access Amazon S3 over IPv6 by using dual-stack endpoints. For more information, see Making requests to Amazon S3 over IPv6 in the *Amazon S3 API Reference*.	August 11, 2016
Asia Pacific (Mumbai) Region	Amazon S3 is now available in the Asia Pacific (Mumbai) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	June 27, 2016

Change	Description	Date
Amazon S3 Transfer Acceleration	Amazon S3 Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of Amazon CloudFront globally distributed edge locations. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.	April 19, 2016
Lifecycle support to remove expired object delete markers	Lifecycle configuration `Expiration` action now allows you to direct Amazon S3 to remove expired object delete markers in a/ versioned bucket. For more information, see Elements to describe lifecycle actions.	March 16, 2016

Change	Description	Date
Bucket lifecycle configuration now supports action to stop incomplete multipart uploads	Bucket lifecycle configuration now supports the `AbortIncompleteMultipartUpload` action that you can use to direct Amazon S3 to stop multipart uploads that don't complete within a specified number of days after being initiated. When a multipart upload becomes eligible for a stop operation, Amazon S3 deletes any uploaded parts and stops the multipart upload. For conceptual information, see the following topics in the *Amazon S3 User Guide*: • Aborting a multipart upload • Elements to describe lifecycle actions The following API operations have been updated to support the new action: • PUT Bucket lifecycle – The XML configuration now allows you to specify the `AbortIncompleteMultipartUpload` action in a lifecycle configuration rule. • List Parts and Initiate Multipart Upload – Both of these API operations now return two additional response headers (`x-amz-abort-date` , and `x-amz-abort-rule-id`) if the bucket has a lifecycle rule that specifies the `AbortIncompleteMultipartUpload` action. These headers in the response indicate when the initiated multipart upload becomes eligible for a stop operation and which lifecycle rule is applicable.	March 16, 2016

Change	Description	Date
Asia Pacific (Seoul) Region	Amazon S3 is now available in the Asia Pacific (Seoul) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	January 6, 2016
New condition key and a multipart upload change	IAM policies now support an Amazon S3 `s3:x-amz-storage-class` condition key. For more information, see Bucket policy examples using condition keys. You no longer need to be the initiator of a multipart upload to upload parts and complete the upload. For more information, see Multipart upload API and permissions.	December 14, 2015
Renamed the US Standard Region	Changed the Region name string from "US Standard" to "US East (N. Virginia)." This is only a Region name update, there is no change in the functionality.	December 11, 2015
New storage class	Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes. Lifecycle configuration feature updates now allow you to transition objects to the STANDARD_IA storage class. For more information, see Managing the lifecycle of objects. Previously, the Cross-Region Replication feature used the storage class of the source object for object replicas. Now, when you configure Cross-Region Replication, you can specify a storage class for the object replica created in the destination bucket. For more information, see Replicating objects within and across Regions.	September 16, 2015

Change	Description	Date
AWS CloudTrail integration	New AWS CloudTrail integration allows you to record Amazon S3 API activity in your S3 bucket. You can use CloudTrail to track S3 bucket creations or deletions, access control modifications, or lifecycle configuration changes. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.	September 1, 2015
Bucket limit increase	Amazon S3 now supports bucket limit increases. By default, customers can create up to 100 buckets in their AWS account. Customers who need additional buckets can increase that limit by submitting a service limit increase. For information about how to increase your bucket limit, go to AWS service quotas in the *AWS General Reference*. For more information, see Using the AWS SDKs and General purpose bucket quotas, limitations, and restrictions.	August 4, 2015
Consistency model update	Amazon S3 now supports read-after-write consistency for new objects added to Amazon S3 in the US East (N. Virginia) Region. Prior to this update, all Regions except US East (N. Virginia) Region supported read-after-write consistency for new objects uploaded to Amazon S3. With this enhancement, Amazon S3 now supports read-after-write consistency in all Regions for new objects added to Amazon S3. Read-after-write consistency allows you to retrieve objects immediately after creation in Amazon S3. For more information, see Regions.	August 4, 2015
Event notifications	Amazon S3 Event Notifications have been updated to add notifications when objects are deleted and to add filtering on object names with prefix and suffix matching. For more information, see Amazon S3 Event Notifications.	July 28, 2015

Change	Description	Date
Amazon CloudWatch integration	New Amazon CloudWatch integration allows you to monitor and set alarms on your Amazon S3 usage through CloudWatch metrics for Amazon S3. Supported metrics include total bytes for Standard storage, total bytes for Reduced-Redundancy Storage, and total number of objects for a given S3 bucket. For more information, see Monitoring metrics with Amazon CloudWatch.	July 28, 2015
Support for deleting and emptying non-empty buckets	Amazon S3 now supports deleting and emptying non-empty buckets. For more information, see Emptying a general purpose bucket.	July 16, 2015
Bucket policies for Amazon VPC endpoints	Amazon S3 has added support for bucket policies for virtual private cloud (VPC) (VPC) endpoints. You can use S3 bucket policies to control access to buckets from specific VPC endpoints, or specific VPCs. VPC endpoints are easy to configure, are highly reliable, and provide a secure connection to Amazon S3 without requiring a gateway or a NAT instance. For more information, see Controlling access from VPC endpoints with bucket policies.	April 29, 2015
Event notifications	Amazon S3 Event Notifications have been updated to support the switch to resource-based permissions for AWS Lambda functions. For more information, see Amazon S3 Event Notifications.	April 9, 2015
Cross-Region Replication	Amazon S3 now supports Cross-Region Replication. Cross-Region Replication is the automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see Replicating objects within and across Regions.	March 24, 2015

Change	Description	Date
Event notifications	Amazon S3 now supports new event types and destinations in a bucket notification configuration. Prior to this release, Amazon S3 supported only the *s3:ReducedRedundancyLostObject* event type and an Amazon SNS topic as the destination. For more information about the new event types, see Amazon S3 Event Notifications.	November 13, 2014
Server-side encryption with customer-provided encryption keys	Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) Amazon S3 now supports server-side encryption using AWS KMS. This feature allows you to manage the envelope key through AWS KMS, and Amazon S3 calls AWS KMS to access the envelope key within the permissions you set. For more information about server-side encryption with AWS KMS, see Protecting Data Using Server-Side Encryption with AWS Key Management Service.	November 12, 2014
Europe (Frankfurt) Region	Amazon S3 is now available in the Europe (Frankfurt) Region.	October 23, 2014
Server-side encryption with customer-provided encryption keys	Amazon S3 now supports server-side encryption using customer-provided encryption keys (SSE-C). Server-side encryption enables you to request Amazon S3 to encrypt your data at rest. When using SSE-C, Amazon S3 encrypts your objects with the custom encryption keys that you provide. Since Amazon S3 performs the encryption for you, you get the benefits of using your own encryption keys without the cost of writing or executing your own encryption code. For more information about SSE-C, see Server-Side Encryption (Using Customer-Provided Encryption Keys).	June 12, 2014

Change	Description	Date
Lifecycle support for versioning	Prior to this release, lifecycle configuration was supported only on nonversioned buckets. Now you can configure lifecycle on both nonversioned and versioning-enabled buckets. For more information, see Managing the lifecycle of objects.	May 20, 2014
Access control topics revised	Revised Amazon S3 access control documentation. For more information, see Identity and Access Management for Amazon S3.	April 15, 2014
Server access logging topic revised	Revised server access logging documentation. For more information, see Logging requests with server access logging.	November 26, 2013
.NET SDK samples updated to version 2.0	.NET SDK samples in this guide are now compliant to version 2.0.	November 26, 2013
SOAP Support Over HTTP deprecated	SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features will not be supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.	September 20, 2013
IAM policy variable support	IAM policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based information from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, see IAM Policy Variables Overview in the *IAM User Guide*. For examples of policy variables in Amazon S3, see Identity-based policy examples for Amazon S3.	April 3, 2013

Change	Description	Date
Console support for Requester Pays	You can now configure your bucket for Requester Pays by using the Amazon S3 console. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.	December 31, 2012
Root domain support for website hosting	Amazon S3 now supports hosting static websites at the root domain. Visitors to your website can access your site from their browser without specifying **www** in the web address (for example, they can use **example.com** instead of **www.example.com**). Many customers already host static websites on Amazon S3 that are accessible from a **www** subdomain (for example, **www.example.com**). Previously, to support root domain access, you needed to run your own web server to proxy root domain requests from browsers to your website on Amazon S3. Running a web server to proxy requests introduces additional costs, operational burden, and another potential point of failure. Now, you can take advantage of the high availability and durability of Amazon S3 for both **www** and root domain addresses. For more information, see Hosting a static website using Amazon S3.	December 27, 2012
Console revision	Amazon S3 console has been updated. The documentation topics that refer to the console have been revised accordingly.	December 14, 2012

Change	Description	Date
Support for Archiving Data to Amazon Glacier	Amazon S3 now supports a storage option that enables you to utilize Amazon Glacier's low-cost storage service for data archival. To archive objects, you define archival rules identifying objects and a time frame when you want Amazon S3 to archive these objects to Amazon Glacier. You can easily set the rules on a bucket using the Amazon S3 console or programmatically using the Amazon S3 API or AWS SDKs. For more information, see Managing the lifecycle of objects.	November 13, 2012
Support for Website Page Redirects	For a bucket that is configured as a website, Amazon S3 now supports redirecting a request for an object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect. For information about hosting websites, see Hosting a static website using Amazon S3.	October 4, 2012
Support for Cross-Origin Resource Sharing (CORS)	Amazon S3 now supports Cross-Origin Resource Sharing (CORS). CORS defines a way in which client web applications that are loaded in one domain can interact with or access resources in a different domain. With CORS support in Amazon S3, you can build rich client-side web applications on top of Amazon S3 and selectively allow cross-domain access to your Amazon S3 resources. For more information, see Using cross-origin resource sharing (CORS).	August 31, 2012
Support for Cost Allocation Tags	Amazon S3 now supports cost allocation tagging, which allows you to label S3 buckets so you can more easily track their cost against projects or other criteria. For more information about using tagging for buckets, see Using cost allocation S3 bucket tags.	August 21, 2012

Change	Description	Date
Support for MFA-protected API access in bucket policies	Amazon S3 now supports MFA-protected API access, a feature that can enforce AWS Multi-Factor Authentication for an extra level of security when accessing your Amazon S3 resources. It is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, go to AWS Multi-Factor Authentication. You can now require MFA authentication for any requests to access your Amazon S3 resources. To enforce MFA authentication, Amazon S3 now supports the `aws:MultiFactorAuthAge` key in a bucket policy. For an example bucket policy, see Requiring MFA.	July 10, 2012
Object Expiration support	You can use Object Expiration to schedule automatic removal of data after a configured time period. You set object expiration by adding lifecycle configuration to a bucket.	27 December 2011
New Region supported	Amazon S3 now supports the South America (São Paulo) Region. For more information, see Accessing an Amazon S3 general purpose bucket.	December 14, 2011
Multi-Object Delete	Amazon S3 now supports Multi-Object Delete API that enables you to delete multiple objects in a single request. With this feature, you can remove large numbers of objects from Amazon S3 more quickly than using multiple individual DELETE requests. For more information, see Deleting Amazon S3 objects.	December 7, 2011
New Region supported	Amazon S3 now supports the US West (Oregon) Region. For more information, see Buckets and Regions.	November 8, 2011
Documentation Update	Documentation bug fixes.	November 8, 2011

Change	Description	Date
Documentation Update	In addition to documentation bug fixes, this release includes the following enhancements: • New server-side encryption sections using the AWS SDK for PHP and the AWS SDK for Ruby (see Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)).	October 17, 2011
Server-side encryption support	Amazon S3 now supports server-side encryption. It enables you to request Amazon S3 to encrypt your data at rest, that is, encrypt your object data when Amazon S3 writes your data to disks in its data centers. In addition to REST API updates, the AWS SDK for Java and .NET provide necessary functionality to request server-side encryption. You can also request server-side encryption when uploading objects using the AWS Management Console. To learn more about data encryption, go to Using Data Encryption.	October 4, 2011
Documentation Update	In addition to documentation bug fixes, this release includes the following enhancements: • Added Ruby and PHP samples to the Making requests in the *Amazon S3 API Reference* section. • Added sections describing how to generate and use presigned URLs. For more information, see Sharing objects with presigned URLs and Sharing objects with presigned URLs. • Updated an existing section to introduce AWS Explorers for Eclipse and Visual Studio. For more information, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.	September 22, 2011

Change	Description	Date
Support for sending requests using temporary security credentials	In addition to using your AWS account and IAM user security credentials to send authenticated requests to Amazon S3, you can now send requests using temporary security credentials you obtain from AWS Identity and Access Management (IAM). You can use the AWS Security Token Service API or the AWS SDK wrapper libraries to request these temporary credentials from IAM. You can request these temporary security credentials for your own use or hand them out to federated users and applications. This feature enables you to manage your users outside AWS and provide them with temporary security credentials to access your AWS resources. For more information, see Making requests in the *Amazon S3 API Reference*. For more information about IAM support for temporary security credentials, see Temporary Security Credentials in the *IAM User Guide*.	August 3, 2011
Multipart Upload API extended to enable copying objects up to 5 TB	Prior to this release, Amazon S3 API supported copying objects of up to 5 GB in size. To enable copying objects larger than 5 GB, Amazon S3 now extends the multipart upload API with a new operation, `Upload Part (Copy)`. You can use this multipart upload operation to copy objects up to 5 TB in size. For more information, see Copying, moving, and renaming objects. For conceptual information about multipart upload API, see Uploading and copying objects using multipart upload in Amazon S3.	June 21, 2011
SOAP API calls over HTTP disabled	To increase security, SOAP API calls over HTTP are disabled. Authenticated and anonymous SOAP requests must be sent to Amazon S3 using SSL.	June 6, 2011

Change	Description	Date
IAM enables cross-account delegation	Previously, to access an Amazon S3 resource, an IAM user needed permissions from both the parent AWS account and the Amazon S3 resource owner. With cross-account access, the IAM user now only needs permission from the owner account. That is, If a resource owner grants access to an AWS account, the AWS account can now grant its IAM users access to these resources. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*. For more information on specifying principals in a bucket policy, see Principals for bucket policies.	June 6, 2011
New link	This service's endpoint information is now located in the *AWS General Reference*. For more information, go to Regions and Endpoints in the AWS General Reference.	March 1, 2011
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, `http://mywebsite.com/subfolder`) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3.	June 6, 2011

Change	Description	Date
This service's endpoint information is now located in the *AWS General Reference*. For more information, go to Regions and Endpoints in the AWS General Reference.	March 1, 2011	
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, `http://mywebsite.com/subfolder`) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3.	February 17, 2011
Response Header API Support	The GET Object REST API now allows you to change the response headers of the REST GET Object request for each request. That is, you can alter object metadata in the response, without altering the object itself. For more information, see Downloading objects.	January 14, 2011
Large object support	Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 GB to 5 TB. If you are using the REST API, you can upload objects of up to 5 GB in a single PUT operation. For larger objects, you must use the Multipart Upload REST API to upload objects in parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3.	December 9, 2010

Change	Description	Date
Multipart upload	Multipart upload enables faster, more flexible uploads into Amazon S3. It allows you to upload a single object as a set of parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3.	November 10, 2010
Canonical ID support in bucket policies	You can now specify canonical IDs in bucket policies. For more information, see Principals for bucket policies	September 17, 2010
Amazon S3 works with IAM	This service now integrates with AWS Identity and Access Management (IAM). For more information, go to AWS services that work with IAM in the *IAM User Guide*.	September 2, 2010
Notifications	The Amazon S3 notifications feature enables you to configure a bucket so that Amazon S3 publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic when Amazon S3 detects a key event on a bucket. For more information, see Setting Up Notification of Bucket Events.	July 14, 2010
Bucket policies	Bucket policies are an access management system that you use to set access permissions across buckets, objects, and sets of objects. This functionality supplements and in many cases replaces access control lists. For more information, see Bucket policies for Amazon S3.	July 6, 2010
Path-style syntax available in all Regions	Amazon S3 now supports the path-style syntax for any bucket in the US Classic Region, or if the bucket is in the same Region as the endpoint of the request. For more information, see Virtual Hosting.	June 9, 2010
New endpoint for Europe (Ireland)	Amazon S3 now provides an endpoint for Europe (Ireland) : `http://s3-eu-west-1.amazonaws.com` .	June 9, 2010

Change	Description	Date
Console	You can now use Amazon S3 through the AWS Management Console. You can read about all of the Amazon S3 functionality in the console in the Amazon Simple Storage Service User Guide.	June 9, 2010
Reduced Redundancy	Amazon S3 now enables you to reduce your storage costs by storing objects in Amazon S3 with reduced redundancy. For more information, see Reduced Redundancy Storage.	May 12, 2010
New Region supported	Amazon S3 now supports the Asia Pacific (Singapore) Region. For more information, see Buckets and Regions.	April 28, 2010
Object Versioning	This release introduces object versioning. All objects now can have a key and a version. If you enable versioning for a bucket, Amazon S3 gives all objects added to a bucket a unique version ID. This feature enables you to recover from unintended overwrites and deletions. For more information, see Versioning and Using Versioning.	February 8, 2010
New Region supported	Amazon S3 now supports the US West (N. California) Region. The new endpoint for requests to this Region is `s3-us-west-1.amazonaws.com`. For more information, see Buckets and Regions.	December 2, 2009
AWS SDK for .NET	AWS now provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using .NET language-specific API operations instead of REST or SOAP. These libraries provide basic functions (not included in the REST or SOAP APIs), such as request authentication, request retries, and error handling so that it's easier to get started. For more information about language-specific libraries and resources, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.	November 11, 2009
