`StopInstances`

The following code example shows how to use `StopInstances`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
##############################################################################
# function ec2_stop_instances
#
# This function stops one or more Amazon Elastic Compute Cloud (Amazon EC2)
 instances.
#
# Parameters:
#       -i instance_id - The ID(s) of the instance(s) to stop (comma-separated).
#       -h - Display help.
#
# Returns:
#       0 - If successful.
#       1 - If it fails.
##############################################################################
function ec2_stop_instances() {
  local instance_ids
  local option OPTARG # Required to use getopts command in a function.

  # bashsupport disable=BP5008
  function usage() {

Scenarios

Configure container service connectivity

The following code example shows how to:

- Create the VPC infrastructure
- Set up logging
- Create the ECS cluster
- Configure IAM roles
- Create the service with Service Connect
- Verify the deployment
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS Service Connect Tutorial Script v4 - Modified to use Default VPC
# This script creates an ECS cluster with Service Connect and deploys an nginx
 service
# Uses the default VPC to avoid VPC limits

set -e  # Exit on any error

# Configuration
SCRIPT_NAME="ECS Service Connect Tutorial"
LOG_FILE="ecs-service-connect-tutorial-v4-default-vpc.log"
REGION=${AWS_DEFAULT_REGION:-${AWS_REGION:-$(aws configure get region 2>/dev/null)}}
if [ -z "$REGION" ]; then
    echo "ERROR: No AWS region configured."
    echo "Set one with: aws configure set region us-east-1"
    exit 1
fi
ENV_PREFIX="tutorial"
CLUSTER_NAME="${ENV_PREFIX}-cluster"
NAMESPACE_NAME="service-connect"

# Generate random suffix for unique resource names
```

```
RANDOM_SUFFIX=$(openssl rand -hex 6)

# Arrays to track created resources for cleanup
declare -a CREATED_RESOURCES=()

# Logging function

Create a basic virtual private network

The following code example shows how to:

- Create a VPC
- Create subnets
- Configure internet connectivity
- Create a NAT Gateway
- Configure subnet settings
- Create security groups
- Verify your VPC configuration

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash
```

```
# VPC Creation Script
# This script creates a VPC with public and private subnets, internet gateway, NAT
 gateway, and security groups

# Set up logging
LOG_FILE="vpc_creation.log"

Create a container task for the serverless launch type

The following code example shows how to:

- Create the cluster
- Create a task definition
- Create the service
- Clean up

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon ECS Fargate Tutorial Script - Version 5
# This script creates an ECS cluster, task definition, and service using Fargate

Creating a container service for virtual machine instances

The following code example shows how to:

- Create an ECS cluster
- Create and monitor a service
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS EC2 Launch Type Tutorial Script - UPDATED VERSION
# This script demonstrates creating an ECS cluster, launching a container instance,
# registering a task definition, and creating a service using the EC2 launch type.
# Updated to match the tutorial draft with nginx web server and service creation.
#
# - UPDATED: Changed from sleep task to nginx web server with service

set -e  # Exit on any error

Creating a relational database instance

The following code example shows how to:

- Set up networking components
- Create a DB subnet group
- Create a DB instance
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to create an Amazon RDS DB instance
# This script follows the tutorial at https://docs.aws.amazon.com/AmazonRDS/latest/
UserGuide/USER_CreateDBInstance.html

# Set up logging
LOG_FILE="rds_creation_$(date +%Y%m%d_%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting RDS DB instance creation script - $(date)"
echo "All actions will be logged to $LOG_FILE"
echo "================================================"
```

```

Get started with dedicated network connections

The following code example shows how to:

- Use ec2 CreateVpnGateway
- Use ec2 DeleteVpnGateway
- Use ec2 DescribeVpnGateways
- Use directconnect CreateConnection
- Use directconnect CreatePrivateVirtualInterface
- Use directconnect DeleteConnection

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

Getting started with document databases

The following code example shows how to:

- Create a DB subnet group
- Create a DocumentDB cluster
- Create a DocumentDB instance
- Configure security and connectivity
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash
# Amazon DocumentDB - Getting Started
# This script creates a DocumentDB cluster with encrypted storage, stores the
# master password in Secrets Manager, and displays connection information.

Getting started with graph databases

The following code example shows how to:

- Create a VPC for your Neptune database
- Create subnets in multiple availability zones
- Configure security for your Neptune database
- Create a Neptune DB subnet group
- Create a Neptune DB cluster and instance
- Add data to your graph database
- Query your graph database

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Neptune Getting Started Script
# This script creates an Amazon Neptune database cluster and demonstrates basic
 operations

# Set up logging
LOG_FILE="neptune-setup.log"

Getting started with load balancing

The following code example shows how to:

- Create an Application Load Balancer
- Create a target group
- Create a listener
- Verify your configuration
- Add an HTTPS listener (optional)
- Add path-based routing (optional)
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Elastic Load Balancing Getting Started Script - v2
# This script creates an Application Load Balancer with HTTP listener and target
 group

set -euo pipefail

# Set up logging

Getting started with network transit gateways

The following code example shows how to:

- Create a transit gateway
- Attach your VPCs to your transit gateway
- Add routes between the transit gateway and your VPCs
- Test the transit gateway
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon VPC Transit Gateway CLI Script
# This script demonstrates how to create a transit gateway and connect two VPCs
# Modified to work with older AWS CLI versions that don't support transit gateway
 wait commands
# Security improved: Added input validation, error handling, and credential checks

# Error handling
set -euo pipefail

Run CPU stress tests on virtual machine instances using fault injection

The following code example shows how to:

- Create IAM roles
- Create a CloudWatch alarm
- Create an experiment template
- Run the experiment
- Verify the results
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

Virtual private network with IP address management

The following code example shows how to:

- Set up and configure Amazon VPC IP Address Manager (IPAM) using the CLI.
- Create an IPAM with operating regions (e.g., us-east-1, us-west-2).
- Retrieve the private scope ID for the IPAM.
- Create a hierarchical structure of IPv4 pools (top-level, regional, and development pools).
- Provision CIDR blocks to each pool (e.g., 10.0.0.0/8, 10.0.0.0/16, 10.0.0.0/24).
- Create a VPC using a CIDR allocated from an IPAM pool.
- Verify IPAM pool allocations and VPC creation.
- Troubleshoot common issues like permission errors, CIDR allocation failures, and dependency violations.
- Clean up IPAM resources (VPC, pools, CIDRs, and IPAM) to avoid unnecessary charges.
- Explore next steps for advanced IPAM features.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# IPAM Getting Started CLI Script - Version 7
# This script creates an IPAM, creates a hierarchy of IP address pools, and
 allocates a CIDR to a VPC
# Fixed to correctly identify the private scope ID, wait for resources to be
 available, add locale to development pool,
# use the correct parameter names for VPC creation, and wait for CIDR provisioning
 to complete

# Set up logging

The following code example shows how to:

- Create a VPC with private subnets and NAT gateways using the CLI.
- Set up the necessary components including VPC, subnets, route tables, and NAT gateways.
- Configure security groups and IAM roles for proper access and security.
- Use CLI commands to automate the creation and configuration of these resources.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# VPC with Private Subnets and NAT Gateways (IMDSv2 Compliant Version)
# This script creates a VPC with public and private subnets in two Availability
 Zones,
# NAT gateways, an internet gateway, route tables, a VPC endpoint for S3,
# security groups, a launch template, an Auto Scaling group, and an Application Load
 Balancer.
```

```

Working with block storage encryption, snapshots, and volume initialization

The following code example shows how to:

- Enable Amazon EBS encryption by default
- Create an EBS snapshot
- Create and initialize a volume from a snapshot
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script for EBS operations: encryption, snapshots, and volume initialization
# This script demonstrates:
# 1. Enabling EBS encryption by default
# 2. Creating an EBS snapshot
# 3. Creating a volume from a snapshot
# Cost optimizations:
# - Reduced volume size from 1 GiB to 100 MiB for testing
# - Changed volume type to gp3 with cost-optimized IOPS/throughput
# - Added early cleanup to minimize storage duration
# - Removed unnecessary API calls for KMS key retrieval

set -euo pipefail

# Security: Restrict file permissions for log files
umask 0077

# Setup logging with secure permissions
LOG_FILE="ebs-operations-v4.log"
exec > >(tee -a "$LOG_FILE") 2>&1

Amazon ECR examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon ECR.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with container registries

The following code example shows how to:

- Create a Docker image
- Create an Amazon ECR repository
- Delete resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon ECR Getting Started Script
# This script demonstrates the lifecycle of a Docker image in Amazon ECR

# Set up logging
LOG_FILE="ecr-tutorial.log"
```

Amazon ECS examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon ECS.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Configure container service connectivity

The following code example shows how to:

- Create the VPC infrastructure
- Set up logging
- Create the ECS cluster
- Configure IAM roles
- Create the service with Service Connect
- Verify the deployment
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS Service Connect Tutorial Script v4 - Modified to use Default VPC
# This script creates an ECS cluster with Service Connect and deploys an nginx
 service
# Uses the default VPC to avoid VPC limits

Create a container task for the serverless launch type

The following code example shows how to:

- Create the cluster
- Create a task definition
- Create the service
- Clean up

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon ECS Fargate Tutorial Script - Version 5
# This script creates an ECS cluster, task definition, and service using Fargate
 launch type
# Fixed version with proper resource dependency handling during cleanup
# Security improvements applied
```

Creating a container service for virtual machine instances

The following code example shows how to:

- Create an ECS cluster
- Create and monitor a service
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS EC2 Launch Type Tutorial Script - UPDATED VERSION
# This script demonstrates creating an ECS cluster, launching a container instance,
# registering a task definition, and creating a service using the EC2 launch type.
# Updated to match the tutorial draft with nginx web server and service creation.
#
# - UPDATED: Changed from sleep task to nginx web server with service

set -e  # Exit on any error

Amazon EKS examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon EKS.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with managed kubernetes clusters

The following code example shows how to:

- Create a VPC for your EKS cluster
- Create IAM roles for your EKS cluster
- Create your EKS cluster
- Configure kubectl to communicate with your cluster
- Create a managed node group
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon EKS Cluster Creation Script (v2)
```

```
# This script creates an Amazon EKS cluster with a managed node group using the AWS
 CLI

# Set up logging
LOG_FILE="eks-cluster-creation-v2.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon EKS cluster creation script at $(date)"
echo "All commands and outputs will be logged to $LOG_FILE"

Getting started with load balancing

The following code example shows how to:

- Create an Application Load Balancer
- Create a target group
- Create a listener
- Verify your configuration
- Add an HTTPS listener (optional)

- Add path-based routing (optional)
- Clean up resources

AWS CLI with Bash script

> **Note**

Amazon EMR examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon EMR.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with big data processing clusters

The following code example shows how to:

- Create an EC2 key pair
- Set up storage and prepare your application
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# EMR Getting Started Tutorial Script
# This script automates the steps in the Amazon EMR Getting Started tutorial

OpenSearch Service examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with OpenSearch Service.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with search and analytics engines

The following code example shows how to:

- Create an OpenSearch Service domain
- Upload data to your domain
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon OpenSearch Service Getting Started Script - Version 8 Fixed
# This script creates an OpenSearch domain, uploads data, searches documents, and
 cleans up resources
# Based on the tested and working 4-tutorial-final.md

# SECURITY IMPROVEMENTS IN THIS VERSION:
# 1. Removed hardcoded passwords - now generated securely
# 2. Improved access policy to use principle of least privilege
# 3. Added credential masking in logs
# 4. Removed credentials from command output
# 5. Added input validation for AWS region
# 6. Improved error handling and validation
# 7. Added secure temporary file handling
# 8. Removed unnecessary curl insecurity flags
# 9. Added better secret management practices
# 10. Improved resource tagging for better governance

AWS FIS examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with AWS FIS.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Run CPU stress tests on virtual machine instances using fault injection

The following code example shows how to:

- Create IAM roles
- Create a CloudWatch alarm
- Create an experiment template
- Run the experiment
- Verify the results
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS FIS CPU Stress Test Tutorial Script
# This script automates the steps in the AWS FIS CPU stress test tutorial

#    approach using epoch time calculations that work across all Linux distributions

# Set up logging
LOG_FILE="fis-tutorial-$(date +%Y%m%d-%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting AWS FIS CPU Stress Test Tutorial Script"
echo "Logging to $LOG_FILE"

AWS Glue examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with AWS Glue.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Scenarios

Getting started with the data catalog

The following code example shows how to:

- Create a database
- Create a table
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Glue Data Catalog Tutorial Script
# This script demonstrates how to create and manage AWS Glue Data Catalog resources
 using the AWS CLI
# Cost improvements: Reduced API calls, optimized queries, eliminated redundant
 operations
# Reliability improvements: Enhanced error handling, input validation, resource
 tracking

set -euo pipefail

# Setup logging
LOG_FILE="glue-tutorial-$(date +%Y%m%d-%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting AWS Glue Data Catalog tutorial script at $(date)"
echo "All operations will be logged to $LOG_FILE"
```

```
# Generate a unique identifier for resource names

Actions

`CreateDatastore`

The following code example shows how to use `CreateDatastore`.

AWS CLI with Bash script

```
##############################################################################
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
##############################################################################
function errecho() {
  printf "%s\n" "$*" 1>&2
}

##############################################################################
# function imaging_create_datastore
#
# This function creates an AWS HealthImaging data store for importing DICOM P10
 files.
#
# Parameters:
#       -n data_store_name - The name of the data store.
#
# Returns:
#       The datastore ID.
#    And:
#       0 - If successful.
#       1 - If it fails.
##############################################################################
function imaging_create_datastore() {
  local datastore_name response
  local option OPTARG # Required to use getopts command in a function.
```

```
  # bashsupport disable=BP5008
  function usage() {
    echo "function imaging_create_datastore"
    echo "Creates an AWS HealthImaging data store for importing DICOM P10 files."
    echo "  -n data_store_name - The name of the data store."
    echo ""
  }

  # Retrieve the calling parameters.
  while getopts "n:h" option; do
    case "${option}" in
      n) datastore_name="${OPTARG}" ;;
      h)
        usage
        return 0
        ;;
      \?)
        echo "Invalid parameter"
        usage
        return 1
        ;;
    esac
  done
  export OPTIND=1

  if [[ -z "$datastore_name" ]]; then
    errecho "ERROR: You must provide a data store name with the -n parameter."
    usage
    return 1
  fi

  response=$(aws medical-imaging create-datastore \
    --datastore-name "$datastore_name" \
    --output text \
    --query 'datastoreId')

  local error_code=${?}

  if [[ $error_code -ne 0 ]]; then

Basics

Learn the basics

The following code example shows how to create a user and assume a role.

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as AWS IAM Identity Center.

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
###############################################################################
# function iam_create_user_assume_role
#
# Scenario to create an IAM user, create an IAM role, and apply the role to the
 user.
#
#     "IAM access" permissions are needed to run this code.
#     "STS assume role" permissions are needed to run this code. (Note: It might be
 necessary to
#           create a custom policy).
#
# Returns:
#       0 - If successful.
```

```
#       1 - If an error occurred.

Actions

`AttachRolePolicy`

The following code example shows how to use `AttachRolePolicy`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
##############################################################################
```

```
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
#############################################################################
function errecho() {
  printf "%s\n" "$*" 1>&2
}

#############################################################################
# function iam_attach_role_policy
#
# This function attaches an IAM policy to a tole.
#
# Parameters:
#       -n role_name -- The name of the IAM role.
#       -p policy_ARN -- The IAM policy document ARN..
#
# Returns:
#       0 - If successful.
#       1 - If it fails.
#############################################################################
function iam_attach_role_policy() {
  local role_name policy_arn response
  local option OPTARG # Required to use getopts command in a function.

  # bashsupport disable=BP5008
  function usage() {
    echo "function iam_attach_role_policy"
    echo "Attaches an AWS Identity and Access Management (IAM) policy to an IAM
 role."
    echo "  -n role_name   The name of the IAM role."
    echo "  -p policy_ARN -- The IAM policy document ARN."
    echo ""
  }

  # Retrieve the calling parameters.
  while getopts "n:p:h" option; do
    case "${option}" in
      n) role_name="${OPTARG}" ;;
      p) policy_arn="${OPTARG}" ;;
      h)
        usage
        return 0
        ;;
```

```
      \?)
        echo "Invalid parameter"
        usage
        return 1
        ;;
    esac

Scenarios

Configure container service connectivity

The following code example shows how to:

- Create the VPC infrastructure
- Set up logging
- Create the ECS cluster
- Configure IAM roles
- Create the service with Service Connect
- Verify the deployment
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS Service Connect Tutorial Script v4 - Modified to use Default VPC
# This script creates an ECS cluster with Service Connect and deploys an nginx
 service
# Uses the default VPC to avoid VPC limits

set -e  # Exit on any error

# Configuration
SCRIPT_NAME="ECS Service Connect Tutorial"
LOG_FILE="ecs-service-connect-tutorial-v4-default-vpc.log"
REGION=${AWS_DEFAULT_REGION:-${AWS_REGION:-$(aws configure get region 2>/dev/null)}}
if [ -z "$REGION" ]; then
    echo "ERROR: No AWS region configured."

Create a container task for the serverless launch type

The following code example shows how to:

- Create the cluster

- Create a task definition
- Create the service
- Clean up

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon ECS Fargate Tutorial Script - Version 5
# This script creates an ECS cluster, task definition, and service using Fargate
 launch type
# Fixed version with proper resource dependency handling during cleanup
# Security improvements applied

set -e  # Exit on any error

# Initialize logging

Create a rest API with function proxy integration

The following code example shows how to:

- Create an IAM role for Lambda execution
- Create and deploy a Lambda function
- Create a REST API
- Configure Lambda proxy integration
- Deploy and test the API
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

set -euo pipefail

# Simple API Gateway Lambda Integration Script
# This script creates a REST API with Lambda proxy integration

# Generate random identifiers
FUNCTION_NAME="GetStartedLambdaProxyIntegration-$(openssl rand -hex 4)"
```

```
ROLE_NAME="GetStartedLambdaBasicExecutionRole-$(openssl rand -hex 4)"
API_NAME="LambdaProxyAPI-$(openssl rand -hex 4)"

Creating a container service for virtual machine instances

The following code example shows how to:

- Create an ECS cluster
- Create and monitor a service
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS EC2 Launch Type Tutorial Script - UPDATED VERSION
# This script demonstrates creating an ECS cluster, launching a container instance,
# registering a task definition, and creating a service using the EC2 launch type.
# Updated to match the tutorial draft with nginx web server and service creation.
#
# - UPDATED: Changed from sleep task to nginx web server with service

set -e  # Exit on any error

# Configuration
SCRIPT_NAME="ecs-ec2-tutorial"

Creating a managed monitoring workspace

The following code example shows how to:

- Create an IAM role for your workspace
- Create a Grafana workspace
- Configure authentication
- Configure optional settings
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Managed Grafana Workspace Creation Script
# This script creates an Amazon Managed Grafana workspace and configures it
```

```
# Set up logging
LOG_FILE="grafana-workspace-creation.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon Managed Grafana workspace creation script at $(date)"
echo "All commands and outputs will be logged to $LOG_FILE"

# Function to check for errors in command output

Creating a monitoring dashboard with function name as a variable

The following code example shows how to:

- Create a CloudWatch dashboard
- Add Lambda metrics widgets with a function name variable
- Verify the dashboard
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to create a CloudWatch dashboard with Lambda function name as a variable
# This script creates a CloudWatch dashboard that allows you to switch between
 different Lambda functions

# Set up logging with secure permissions

Creating your first serverless function

The following code example shows how to:

- Create an IAM role for Lambda
- Create function code
- Create a Lambda function
- Test your Lambda function
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash
# AWS Lambda - Create Your First Function
# This script creates a Lambda function, invokes it with a test event,
# views CloudWatch logs, and cleans up all resources.
#
```

```
# Source: https://docs.aws.amazon.com/lambda/latest/dg/getting-started.html
#
# Resources created:
#   - IAM role (Lambda execution role with basic logging permissions)
#   - Lambda function (Python 3.13 or Node.js 22.x runtime)
#   - CloudWatch log group (created automatically by Lambda on invocation)

  - GetFunction
  - GetFunctionConfiguration
  - GetLogEvents
  - Invoke

Get started with serverless data warehouses

The following code example shows how to:

- Use secrets-manager CreateSecret
- Use secrets-manager DeleteSecret
- Use secrets-manager GetSecretValue
- Use redshift CreateNamespace
- Use redshift CreateWorkgroup
- Use redshift DeleteNamespace
- Use iam CreateRole

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

Getting started with configuration management

The following code example shows how to:

- Create an Amazon S3 bucket
- Create an Amazon SNS topic
- Create an IAM role for Config
- Set up the Config configuration recorder
- Set up the Config delivery channel
- Start the configuration recorder
- Verify the Config setup

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Config Setup Script (v2)
# This script sets up AWS Config with the AWS CLI

# Error handling
set -e
LOGFILE="aws-config-setup-v2.log"
touch $LOGFILE
exec > >(tee -a $LOGFILE)
exec 2>&1

# Function to handle errors
handle_error() {
    echo "ERROR: An error occurred at line $1"

  - DetachRolePolicy
  - GetCallerIdentity
  - PutConfigurationRecorder
  - PutDeliveryChannel
  - PutPublicAccessBlock
  - PutRolePolicy
  - Rm
  - StartConfigurationRecorder
  - StopConfigurationRecorder

Getting started with internet of things device protection

The following code example shows how to:

- Create Required IAM Roles
- Enable IoT Device Defender Audit Checks
- Run an On-Demand Audit
- Create a Mitigation Action

- Apply Mitigation Actions to Findings
- Set Up SNS Notifications (Optional)
- Enable IoT Logging

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS IoT Device Defender Getting Started Script
# This script demonstrates how to use AWS IoT Device Defender to enable audit
 checks,
# view audit results, create mitigation actions, and apply them to findings.

set -euo pipefail

# Set up logging
LOG_FILE="iot-device-defender-script-$(date +%Y%m%d%H%M%S).log"

Getting started with machine learning feature stores

The following code example shows how to:

- Set up IAM permissions

- Create a SageMaker execution role
- Create feature groups
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon SageMaker Feature Store Tutorial Script - Version 3

Getting started with managed kubernetes clusters

The following code example shows how to:

- Create a VPC for your EKS cluster
- Create IAM roles for your EKS cluster
- Create your EKS cluster
- Configure kubectl to communicate with your cluster
- Create a managed node group
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon EKS Cluster Creation Script (v2)
# This script creates an Amazon EKS cluster with a managed node group using the AWS
 CLI

# Set up logging
LOG_FILE="eks-cluster-creation-v2.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon EKS cluster creation script at $(date)"
echo "All commands and outputs will be logged to $LOG_FILE"
```

```
# Error handling function
handle_error() {
    echo "ERROR: $1"
    echo "Attempting to clean up resources..."
    cleanup_resources
    exit 1
}

# Function to check command success

Getting started with provisioned data warehouse clusters

The following code example shows how to:

- Create a Redshift cluster
- Create an IAM role for S3 access
- Create tables and load data

- Run example queries
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Redshift Provisioned Cluster Tutorial Script
# This script creates a Redshift cluster, loads sample data, runs queries, and
 cleans up resources
# Version 4: Security improvements and best practices

set -euo pipefail

# Set up logging

  - CreateCluster
  - CreateRole
  - DeleteCluster
  - DeleteRole

- DeleteRolePolicy
- DescribeClusters
- GetRole
- ModifyClusterIamRoles
- PutRolePolicy
- Wait

Getting started with workflow orchestration

The following code example shows how to:

- Create an IAM role for Step Functions
- Create your first state machine
- Start your state machine execution
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Step Functions Getting Started Tutorial Script
# This script creates and runs a Step Functions state machine based on the AWS Step
 Functions Getting Started tutorial

set -euo pipefail

# Security: Restrict umask to prevent unintended file permissions
umask 077

# Parse command line arguments

  - DescribeExecution
  - DetachRolePolicy
  - StartExecution
  - UpdateStateMachine

Moving hardcoded secrets to secure secret storage

The following code example shows how to:

- Create IAM roles
- Create a secret in Secrets Manager
- Update your application code
- Update the secret
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to move hardcoded secrets to AWS Secrets Manager
# This script demonstrates how to create IAM roles, store a secret in AWS Secrets
 Manager,
# and set up appropriate permissions

set -euo pipefail

# Set up logging
LOG_FILE="secrets_manager_tutorial.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting AWS Secrets Manager tutorial script at $(date)"
echo "============================================================"

- For API details, see the following topics in *AWS CLI Command Reference*.
  - AttachRolePolicy
  - CreateRole
  - CreateSecret
  - DeleteRole
  - DeleteSecret
  - DetachRolePolicy
  - GetCallerIdentity
  - GetSecretValue
  - PutResourcePolicy
  - UpdateSecret

Run CPU stress tests on virtual machine instances using fault injection

The following code example shows how to:

- Create IAM roles

- Create a CloudWatch alarm
- Create an experiment template
- Run the experiment
- Verify the results
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

Set up Attribute-Based Access Control

The following code example shows how to implement Attribute-Based Access Control (ABAC) for DynamoDB.

- Create an IAM policy for ABAC.
- Create tables with tags for different departments.
- List and filter tables based on tags.

AWS CLI with Bash script

Create an IAM policy for ABAC.

```
# Step 1: Create a policy document for ABAC
cat > abac-policy.json << 'EOF'
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:Scan"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Department": "${aws:PrincipalTag/Department}"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem",
        "dynamodb:BatchWriteItem"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Department": "${aws:PrincipalTag/Department}",
          "aws:ResourceTag/Environment": "Development"
        }
```

```
      }
    }
  ]
}
EOF

# Step 2: Create the IAM policy
aws iam create-policy \
    --policy-name DynamoDBDepartmentBasedAccess \
    --policy-document file://abac-policy.json
```

Create tables with tags for different departments.

```
# Create a DynamoDB table with tags for ABAC
aws dynamodb create-table \
    --table-name FinanceData \
    --attribute-definitions \
        AttributeName=RecordID,AttributeType=S \
    --key-schema \
        AttributeName=RecordID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --tags \
        Key=Department,Value=Finance \
        Key=Environment,Value=Development

# Create another table with different tags
aws dynamodb create-table \
    --table-name MarketingData \
    --attribute-definitions \
        AttributeName=RecordID,AttributeType=S \
    --key-schema \
        AttributeName=RecordID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --tags \
        Key=Department,Value=Marketing \
        Key=Environment,Value=Production
```

List and filter tables based on tags.

```
# List all DynamoDB tables
echo "Listing all tables:"
```

```
aws dynamodb list-tables

# Get ARNs for all tables
echo -e "\nGetting ARNs for all tables:"
TABLE_ARNS=$(aws dynamodb list-tables --query "TableNames[*]" --output text | xargs
 -I {} aws dynamodb describe-table --table-name {} --query "Table.TableArn" --output
 text)

# For each table ARN, list its tags
echo -e "\nListing tags for each table:"
for ARN in $TABLE_ARNS; do
    TABLE_NAME=$(echo $ARN | awk -F/ '{print $2}')
    echo -e "\nTags for table: $TABLE_NAME"
    aws dynamodb list-tags-of-resource --resource-arn $ARN
done

# Example: Find tables with a specific tag
echo -e "\nFinding tables with Environment=Production tag:"
for ARN in $TABLE_ARNS; do
    TABLE_NAME=$(echo $ARN | awk -F/ '{print $2}')
    TAGS=$(aws dynamodb list-tags-of-resource --resource-arn $ARN --query "Tags[?
Key=='Environment' && Value=='Production']" --output text)
    if [ ! -z "$TAGS" ]; then
        echo "Table with Production tag: $TABLE_NAME"
    fi
done
```

- For API details, see the following topics in *AWS CLI Command Reference*.
  - CreatePolicy
  - CreateTable
  - ListTables

Setting up systems management

The following code example shows how to:

- Create IAM permissions for Systems Manager
- Create an IAM role for Systems Manager
- Configure Systems Manager

- Verify the setup
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Systems Manager Setup Script
# This script sets up AWS Systems Manager for a single account and region
#
# Version 17 fixes:
# 1. Added cloudformation.amazonaws.com to the IAM role trust policy
# 2. Systems Manager Quick Setup uses CloudFormation for deployments, so the role
 must trust CloudFormation service

# Initialize log file
LOG_FILE="ssm_setup_$(date +%Y%m%d_%H%M%S).log"

Work with Streams and Time-to-Live

The following code example shows how to manage DynamoDB Streams and Time-to-Live features.

- Create a table with Streams enabled.
- Describe Streams.

- Create a Lambda function for processing Streams.
- Enable TTL on a table.
- Add items with TTL attributes.
- Describe TTL settings.

AWS CLI with Bash script

Create a table with Streams enabled.

```
# Create a table with DynamoDB Streams enabled
aws dynamodb create-table \
    --table-name StreamsDemo \
    --attribute-definitions \
        AttributeName=ID,AttributeType=S \
    --key-schema \
        AttributeName=ID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES
```

Describe Streams.

```
# Get information about the stream
aws dynamodb describe-table \
    --table-name StreamsDemo \
    --query "Table.StreamSpecification"

# Get the stream ARN
STREAM_ARN=$(aws dynamodb describe-table \
    --table-name StreamsDemo \
    --query "Table.LatestStreamArn" \
    --output text)

echo "Stream ARN: $STREAM_ARN"

# Describe the stream
aws dynamodbstreams describe-stream \
    --stream-arn $STREAM_ARN
```

Create a Lambda function for Streams.

```
# Step 1: Create an IAM role for the Lambda function
cat > trust-policy.json << 'EOF'
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
EOF

aws iam create-role \
    --role-name DynamoDBStreamsLambdaRole \
    --assume-role-policy-document file://trust-policy.json

# Step 2: Attach permissions to the role
aws iam attach-role-policy \
    --role-name DynamoDBStreamsLambdaRole \
    --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaDynamoDBExecutionRole

# Step 3: Create a Lambda function (code would be in a separate file)
echo "Lambda function creation would be done separately with appropriate code"

# Step 4: Create an event source mapping
echo "Example command to create event source mapping:"
echo "aws lambda create-event-source-mapping \\"
echo "    --function-name ProcessDynamoDBRecords \\"
echo "    --event-source $STREAM_ARN \\"
echo "    --batch-size 100 \\"
echo "    --starting-position LATEST"
```

Enable TTL on a table.

```
# Create a table for TTL demonstration
aws dynamodb create-table \
    --table-name TTLDemo \
    --attribute-definitions \
```

```
        AttributeName=ID,AttributeType=S \
    --key-schema \
        AttributeName=ID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST

# Wait for table to become active
aws dynamodb wait table-exists --table-name TTLDemo

# Enable TTL on the table
aws dynamodb update-time-to-live \
    --table-name TTLDemo \
    --time-to-live-specification "Enabled=true, AttributeName=ExpirationTime"
```

Add items with TTL attributes.

```
# Calculate expiration time (current time + 1 day in seconds)
EXPIRATION_TIME=$(date -d "+1 day" +%s)

# Add an item with TTL attribute
aws dynamodb put-item \
    --table-name TTLDemo \
    --item '{
        "ID": {"S": "item1"},
        "Data": {"S": "This item will expire in 1 day"},
        "ExpirationTime": {"N": "'$EXPIRATION_TIME'"}
    }'

# Add an item that expires in 1 hour
EXPIRATION_TIME_HOUR=$(date -d "+1 hour" +%s)
aws dynamodb put-item \
    --table-name TTLDemo \
    --item '{
        "ID": {"S": "item2"},
        "Data": {"S": "This item will expire in 1 hour"},
        "ExpirationTime": {"N": "'$EXPIRATION_TIME_HOUR'"}
    }'
```

Describe TTL settings.

```
# Describe TTL settings for a table
aws dynamodb describe-time-to-live \
```

```
    --table-name TTLDemo
```

AWS IoT examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with AWS IoT.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with internet of things device protection

The following code example shows how to:

- Create Required IAM Roles
- Enable IoT Device Defender Audit Checks
- Run an On-Demand Audit
- Create a Mitigation Action

- Apply Mitigation Actions to Findings
- Set Up SNS Notifications (Optional)
- Enable IoT Logging

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS IoT Device Defender Getting Started Script
# This script demonstrates how to use AWS IoT Device Defender to enable audit
 checks,
# view audit results, create mitigation actions, and apply them to findings.

set -euo pipefail

# Set up logging
LOG_FILE="iot-device-defender-script-$(date +%Y%m%d%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1

Getting started with internet of things messaging

The following code example shows how to:

- Create IoT resources

- Configure your device
- Run the sample application
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS IoT Core Getting Started Script
# This script creates AWS IoT resources, configures a device, and runs a sample
 application

# Set up logging
LOG_FILE="iot-core-setup.log"
echo "Starting AWS IoT Core setup at $(date)" > $LOG_FILE

# Function to log commands and their outputs
log_cmd() {
    echo "$(date): Running command: $1" >> $LOG_FILE
    eval "$1" 2>&1 | tee -a $LOG_FILE
    return ${PIPESTATUS[0]}
}

# Function to check for errors
check_error() {
    if [ $1 -ne 0 ]; then
        echo "ERROR: Command failed with exit code $1" | tee -a $LOG_FILE
        echo "Please check the log file $LOG_FILE for details" | tee -a $LOG_FILE
        cleanup_on_error
        exit $1
    fi
}

# Function to cleanup resources on error
cleanup_on_error() {
```

```

AWS KMS examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with AWS KMS.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Work with table encryption

The following code example shows how to manage encryption options for DynamoDB tables.

- Create a table with default encryption.
- Create a table with a customer managed CMK.
- Update table encryption settings.
- Describe table encryption.

AWS CLI with Bash script

Create a table with default encryption.

```
# Create a table with default encryption (AWS owned key)
aws dynamodb create-table \
    --table-name CustomerData \
    --attribute-definitions \
        AttributeName=CustomerID,AttributeType=S \
    --key-schema \
        AttributeName=CustomerID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --sse-specification Enabled=true,SSEType=KMS
```

Create a table with a customer managed CMK.

```
# Step 1: Create a customer managed key in KMS
```

```
aws kms create-key \
    --description "Key for DynamoDB table encryption" \
    --key-usage ENCRYPT_DECRYPT \
    --customer-master-key-spec SYMMETRIC_DEFAULT

# Store the key ID for later use
KEY_ID=$(aws kms list-keys --query "Keys[?contains(KeyArn, 'Key for
 DynamoDB')].KeyId" --output text)

# Step 2: Create a table with the customer managed key
aws dynamodb create-table \
    --table-name SensitiveData \
    --attribute-definitions \
        AttributeName=RecordID,AttributeType=S \
    --key-schema \
        AttributeName=RecordID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=$KEY_ID
```

Update table encryption.

```
# Update a table to use a different KMS key
aws dynamodb update-table \
    --table-name CustomerData \
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=$KEY_ID
```

Describe table encryption.

```
# Describe the table to see encryption settings
aws dynamodb describe-table \
    --table-name CustomerData \
    --query "Table.SSEDescription"
```

- For API details, see the following topics in *AWS CLI Command Reference*.
  - CreateKey
  - CreateTable
  - DescribeTable
  - UpdateTable

Lambda examples using AWS CLI with Bash script

Creating a monitoring dashboard with function name as a variable

The following code example shows how to:

- Create a CloudWatch dashboard
- Add Lambda metrics widgets with a function name variable
- Verify the dashboard
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to create a CloudWatch dashboard with Lambda function name as a variable
# This script creates a CloudWatch dashboard that allows you to switch between
 different Lambda functions

# Set up logging with secure permissions
```

```
LOG_FILE="${HOME}/.cloudwatch-dashboard-script.log"
touch "$LOG_FILE" && chmod 600 "$LOG_FILE"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "$(date): Starting CloudWatch dashboard creation script"

Creating your first serverless function

The following code example shows how to:

- Create an IAM role for Lambda
- Create function code
- Create a Lambda function
- Test your Lambda function
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash
# AWS Lambda - Create Your First Function
# This script creates a Lambda function, invokes it with a test event,
# views CloudWatch logs, and cleans up all resources.
#
# Source: https://docs.aws.amazon.com/lambda/latest/dg/getting-started.html
#
# Resources created:
#   - IAM role (Lambda execution role with basic logging permissions)
#   - Lambda function (Python 3.13 or Node.js 22.x runtime)
#   - CloudWatch log group (created automatically by Lambda on invocation)

Neptune examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Neptune.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with graph databases

The following code example shows how to:

- Create a VPC for your Neptune database
- Create subnets in multiple availability zones
- Configure security for your Neptune database
- Create a Neptune DB subnet group
- Create a Neptune DB cluster and instance
- Add data to your graph database
- Query your graph database

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

AWS Payment Cryptography examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with AWS Payment Cryptography.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Getting started with payment security cryptography

The following code example shows how to:

- Create a key
- Verify the CVV2 value
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Payment Cryptography Getting Started Script
# This script demonstrates how to use AWS Payment Cryptography to create a key,
# generate and verify CVV2 values, and clean up resources.

set -euo pipefail

# Initialize log file with secure permissions

Amazon Redshift examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon Redshift.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Get started with serverless data warehouses

The following code example shows how to:

- Use secrets-manager CreateSecret
- Use secrets-manager DeleteSecret
- Use secrets-manager GetSecretValue
- Use redshift CreateNamespace
- Use redshift CreateWorkgroup
- Use redshift DeleteNamespace
- Use iam CreateRole

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Redshift Serverless Tutorial Script with Secrets Manager (No jq dependency)
# This script creates a Redshift Serverless environment, loads sample data, and runs
 queries
# Uses AWS Secrets Manager for secure password management without requiring jq

Getting started with provisioned data warehouse clusters

The following code example shows how to:

- Create a Redshift cluster
- Create an IAM role for S3 access
- Create tables and load data
- Run example queries
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Redshift Provisioned Cluster Tutorial Script
# This script creates a Redshift cluster, loads sample data, runs queries, and
 cleans up resources
# Version 4: Security improvements and best practices

set -euo pipefail

# Set up logging
LOG_FILE="redshift_tutorial.log"
exec > >(tee -a "$LOG_FILE") 2>&1
```

```
echo "Starting Amazon Redshift tutorial script at $(date)"
echo "All commands and outputs will be logged to $LOG_FILE"

Amazon S3 examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon S3.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Basics
- Actions
- Scenarios

Basics

Learn the basics

The following code example shows how to:

- Create a bucket and upload a file to it.
- Download an object from a bucket.
- Copy an object to a subfolder in a bucket.
- List the objects in a bucket.
- Delete the bucket objects and the bucket.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
###############################################################################
# function s3_getting_started
#
# This function creates, copies, and deletes S3 buckets and objects.
#
# Returns:
#       0 - If successful.
#       1 - If an error occurred.
###############################################################################
function s3_getting_started() {
  {
    if [ "$BUCKET_OPERATIONS_SOURCED" != "True" ]; then
      cd bucket-lifecycle-operations || exit
```

```
    source ./bucket_operations.sh
    cd ..
  fi
}

The Amazon S3 functions used in this scenario.

```
###############################################################################
# function create-bucket
#
# This function creates the specified bucket in the specified AWS Region, unless
# it already exists.
#
# Parameters:
#       -b bucket_name  -- The name of the bucket to create.
#       -r region_code  -- The code for an AWS Region in which to
#                          create the bucket.
#
# Returns:

Actions

`CopyObject`

The following code example shows how to use `CopyObject`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
##############################################################################
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
##############################################################################
function errecho() {
  printf "%s\n" "$*" 1>&2
}

##############################################################################
# function copy_item_in_bucket
#
# This function creates a copy of the specified file in the same bucket.
#
# Parameters:
#       $1 - The name of the bucket to copy the file from and to.
#       $2 - The key of the source file to copy.
#       $3 - The key of the destination file.
#
# Returns:
#       0 - If successful.
#       1 - If it fails.
##############################################################################
```

```
function copy_item_in_bucket() {
  local bucket_name=$1
  local source_key=$2
  local destination_key=$3
  local response

  response=$(aws s3api copy-object \
    --bucket "$bucket_name" \
    --copy-source "$bucket_name/$source_key" \
    --key "$destination_key")

  # shellcheck disable=SC2181
  if [[ $? -ne 0 ]]; then
    errecho "ERROR:  AWS reports s3api copy-object operation failed.\n$response"
    return 1
  fi
}
```

- For API details, see CopyObject in *AWS CLI Command Reference*.

`CreateBucket`

The following code example shows how to use `CreateBucket`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
##############################################################################
# function iecho
#
# This function enables the script to display the specified text only if
# the global variable $VERBOSE is set to true.
##############################################################################
function iecho() {
  if [[ $VERBOSE == true ]]; then
    echo "$@"
```

```
  fi
}

###############################################################################
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
###############################################################################
function errecho() {
  printf "%s\n" "$*" 1>&2
}

###############################################################################
# function create-bucket
#
# This function creates the specified bucket in the specified AWS Region, unless
# it already exists.
#
# Parameters:
#       -b bucket_name  -- The name of the bucket to create.
#       -r region_code  -- The code for an AWS Region in which to
#                          create the bucket.
#
# Returns:
#       The URL of the bucket that was created.
#     And:
#       0 - If successful.
#       1 - If it fails.
###############################################################################

    "$destination_file_name")

  # shellcheck disable=SC2181
  if [[ ${?} -ne 0 ]]; then
    errecho "ERROR: AWS reports put-object operation failed.\n$response"
    return 1
  fi
}
```

- For API details, see GetObject in *AWS CLI Command Reference*.

`HeadBucket`

The following code example shows how to use `HeadBucket`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
################################################################################
# function bucket_exists
#
# This function checks to see if the specified bucket already exists.
#
# Parameters:
#       $1 - The name of the bucket to check.
```

```
#
# Returns:
#       0 - If the bucket already exists.
#       1 - If the bucket doesn't exist.
###############################################################################
function bucket_exists() {
  local bucket_name
  bucket_name=$1

  # Check whether the bucket already exists.
  # We suppress all output - we're interested only in the return code.

  if aws s3api head-bucket \
    --bucket "$bucket_name" \
    >/dev/null 2>&1; then
    return 0 # 0 in Bash script means true.
  else
    return 1 # 1 in Bash script means false.
  fi
}
```

- For API details, see HeadBucket in *AWS CLI Command Reference*.

`ListObjectsV2`

The following code example shows how to use `ListObjectsV2`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
###############################################################################
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
###############################################################################
function errecho() {
```

```
  printf "%s\n" "$*" 1>&2
}

#############################################################################
# function list_items_in_bucket
#
# This function displays a list of the files in the bucket with each file's
# size. The function uses the --query parameter to retrieve only the key and
# size fields from the Contents collection.
#
# Parameters:
#       $1 - The name of the bucket.
#
# Returns:
#       The list of files in text format.
#     And:
#       0 - If successful.
#       1 - If it fails.
#############################################################################
function list_items_in_bucket() {
  local bucket_name=$1
  local response

  response=$(aws s3api list-objects \
    --bucket "$bucket_name" \
    --output text \
    --query 'Contents[].{Key: Key, Size: Size}')

  # shellcheck disable=SC2181
  if [[ ${?} -eq 0 ]]; then
    echo "$response"
  else
    errecho "ERROR: AWS reports s3api list-objects operation failed.\n$response"
    return 1
  fi
}
```

- For API details, see ListObjectsV2 in *AWS CLI Command Reference*.

`PutObject`

The following code example shows how to use `PutObject`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
##############################################################################
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
##############################################################################
function errecho() {
  printf "%s\n" "$*" 1>&2
}

##############################################################################
# function copy_file_to_bucket
#
# This function creates a file in the specified bucket.
#
# Parameters:
#       $1 - The name of the bucket to copy the file to.
#       $2 - The path and file name of the local file to copy to the bucket.
#       $3 - The key (name) to call the copy of the file in the bucket.
#
# Returns:
#       0 - If successful.
#       1 - If it fails.
##############################################################################
function copy_file_to_bucket() {
  local response bucket_name source_file destination_file_name

  fi
}
```

- For API details, see PutObject in *AWS CLI Command Reference*.

Scenarios

Getting started with big data processing clusters

The following code example shows how to:

- Create an EC2 key pair
- Set up storage and prepare your application
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# EMR Getting Started Tutorial Script
# This script automates the steps in the Amazon EMR Getting Started tutorial

set -euo pipefail

# Security: Set strict mode and trap errors
trap 'handle_error "Script interrupted or command failed"' ERR

# Set up logging with secure permissions
LOG_FILE="emr-tutorial.log"
```

```
touch "$LOG_FILE"
chmod 600 "$LOG_FILE"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon EMR Getting Started Tutorial Script"
echo "Logging to $LOG_FILE"

# Function to handle errors
handle_error() {
    echo "ERROR: $1"
    echo "Resources created so far:"
    if [ -n "${BUCKET_NAME:-}" ]; then echo "- S3 Bucket: $BUCKET_NAME"; fi
    if [ -n "${CLUSTER_ID:-}" ]; then echo "- EMR Cluster: $CLUSTER_ID"; fi

    echo "Attempting to clean up resources..."
    cleanup
    exit 1
}

# Function to clean up resources
cleanup() {
    echo ""
    echo "========================================="
    echo "CLEANUP IN PROGRESS"
    echo "========================================="
    echo "Starting cleanup process..."

    # Terminate EMR cluster if it exists
    if [ -n "${CLUSTER_ID:-}" ]; then
        echo "Terminating EMR cluster: $CLUSTER_ID"
        aws emr terminate-clusters --cluster-ids "$CLUSTER_ID" 2>/dev/null || true

        echo "Waiting for cluster to terminate..."
        aws emr wait cluster-terminated --cluster-id "$CLUSTER_ID" 2>/dev/null ||
 true

Getting started with configuration management

The following code example shows how to:

- Create an Amazon S3 bucket
- Create an Amazon SNS topic
- Create an IAM role for Config
- Set up the Config configuration recorder
- Set up the Config delivery channel
- Start the configuration recorder
- Verify the Config setup

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Config Setup Script (v2)
# This script sets up AWS Config with the AWS CLI

# Error handling
set -e
LOGFILE="aws-config-setup-v2.log"
touch $LOGFILE
exec > >(tee -a $LOGFILE)
exec 2>&1

Getting started with object storage

The following code example shows how to:

- Create your first S3 bucket
- Upload an object
- Enable versioning
- Configure default encryption
- Add tags to your bucket
- List objects and versions
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash
# S3 Getting Started - Create a bucket, upload and download objects, copy to a
# folder prefix, enable versioning, configure encryption and public access
# blocking, tag the bucket, list objects and versions, and clean up.

Getting started with query analytics

The following code example shows how to:

- Create an S3 bucket for query results
- Create a database
- Create a table
- Run a query
- Create and use named queries
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Athena Getting Started Script
# This script demonstrates how to use Amazon Athena with AWS CLI
# It creates a database, table, runs queries, and manages named queries

set -euo pipefail

SageMaker AI examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with SageMaker AI.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with machine learning feature stores

The following code example shows how to:

- Set up IAM permissions
- Create a SageMaker execution role
- Create feature groups
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon SageMaker Feature Store Tutorial Script - Version 3
# This script demonstrates how to use Amazon SageMaker Feature Store with AWS CLI

Secrets Manager examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Secrets Manager.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Creating a relational database instance

The following code example shows how to:

- Set up networking components
- Create a DB subnet group
- Create a DB instance

- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

  - GetSecretValue
  - GetWorkgroup
  - PutRolePolicy
  - UpdateNamespace

Getting started with document databases

The following code example shows how to:

- Create a DB subnet group
- Create a DocumentDB cluster
- Create a DocumentDB instance
- Configure security and connectivity
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash
# Amazon DocumentDB - Getting Started
# This script creates a DocumentDB cluster with encrypted storage, stores the
# master password in Secrets Manager, and displays connection information.

Moving hardcoded secrets to secure secret storage

The following code example shows how to:

- Create IAM roles

- Create a secret in Secrets Manager
- Update your application code
- Update the secret
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to move hardcoded secrets to AWS Secrets Manager
# This script demonstrates how to create IAM roles, store a secret in AWS Secrets
 Manager,
# and set up appropriate permissions

set -euo pipefail

# Set up logging
LOG_FILE="secrets_manager_tutorial.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting AWS Secrets Manager tutorial script at $(date)"
echo "=================================================="

# Function to check for errors in command output

Getting started with configuration management

The following code example shows how to:

- Create an Amazon S3 bucket
- Create an Amazon SNS topic
- Create an IAM role for Config
- Set up the Config configuration recorder
- Set up the Config delivery channel
- Start the configuration recorder
- Verify the Config setup

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

Getting started with internet of things device protection

The following code example shows how to:

- Create Required IAM Roles
- Enable IoT Device Defender Audit Checks
- Run an On-Demand Audit
- Create a Mitigation Action
- Apply Mitigation Actions to Findings
- Set Up SNS Notifications (Optional)
- Enable IoT Logging

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS IoT Device Defender Getting Started Script
# This script demonstrates how to use AWS IoT Device Defender to enable audit
 checks,
# view audit results, create mitigation actions, and apply them to findings.

set -euo pipefail

# Set up logging
LOG_FILE="iot-device-defender-script-$(date +%Y%m%d%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1
```

```

Step Functions examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Step Functions.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with workflow orchestration

The following code example shows how to:

- Create an IAM role for Step Functions
- Create your first state machine
- Start your state machine execution
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Step Functions Getting Started Tutorial Script
# This script creates and runs a Step Functions state machine based on the AWS Step
 Functions Getting Started tutorial

set -euo pipefail

# Security: Restrict umask to prevent unintended file permissions

AWS STS examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with AWS STS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Actions

`AssumeRole`

The following code example shows how to use `AssumeRole`.

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
###############################################################################
# function iecho
#
# This function enables the script to display the specified text only if
# the global variable $VERBOSE is set to true.
###############################################################################
function iecho() {
  if [[ $VERBOSE == true ]]; then
```

```
    echo "$@"
  fi
}

############################################################################
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
############################################################################
function errecho() {
  printf "%s\n" "$*" 1>&2
}

############################################################################
# function sts_assume_role
#
# This function assumes a role in the AWS account and returns the temporary
#  credentials.
#
# Parameters:
#       -n role_session_name -- The name of the session.
#       -r role_arn -- The ARN of the role to assume.
#
# Returns:
#       [access_key_id, secret_access_key, session_token]
#     And:
#       0 - If successful.
#       1 - If an error occurred.
############################################################################
function sts_assume_role() {
  local role_session_name role_arn response
  local option OPTARG # Required to use getopts command in a function.

  # bashsupport disable=BP5008
  function usage() {
    echo "function sts_assume_role"
    echo "Assumes a role in the AWS account and returns the temporary credentials:"
    echo "  -n role_session_name -- The name of the session."
    echo "  -r role_arn -- The ARN of the role to assume."
    echo ""
  }

  while getopts n:r:h option; do
    case "${option}" in
```

```
      n) role_session_name=${OPTARG} ;;
      r) role_arn=${OPTARG} ;;
      h)
        usage

Scenarios

Configure container service connectivity

The following code example shows how to:

- Create the VPC infrastructure

- Set up logging
- Create the ECS cluster
- Configure IAM roles
- Create the service with Service Connect
- Verify the deployment
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS Service Connect Tutorial Script v4 - Modified to use Default VPC
# This script creates an ECS cluster with Service Connect and deploys an nginx
 service
# Uses the default VPC to avoid VPC limits

set -e  # Exit on any error

# Configuration

Create a container task for the serverless launch type

The following code example shows how to:

- Create the cluster
- Create a task definition
- Create the service
- Clean up

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon ECS Fargate Tutorial Script - Version 5
# This script creates an ECS cluster, task definition, and service using Fargate
 launch type
# Fixed version with proper resource dependency handling during cleanup
# Security improvements applied
```

Create a rest API with function proxy integration

The following code example shows how to:

- Create an IAM role for Lambda execution
- Create and deploy a Lambda function
- Create a REST API
- Configure Lambda proxy integration
- Deploy and test the API
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

set -euo pipefail

Creating a container service for virtual machine instances

The following code example shows how to:

- Create an ECS cluster
- Create and monitor a service
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# ECS EC2 Launch Type Tutorial Script - UPDATED VERSION
# This script demonstrates creating an ECS cluster, launching a container instance,
# registering a task definition, and creating a service using the EC2 launch type.
# Updated to match the tutorial draft with nginx web server and service creation.
#
# - UPDATED: Changed from sleep task to nginx web server with service

set -e  # Exit on any error

# Configuration

Creating a managed monitoring workspace

The following code example shows how to:

- Create an IAM role for your workspace
- Create a Grafana workspace
- Configure authentication
- Configure optional settings
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Managed Grafana Workspace Creation Script
# This script creates an Amazon Managed Grafana workspace and configures it

# Set up logging
LOG_FILE="grafana-workspace-creation.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon Managed Grafana workspace creation script at $(date)"
echo "All commands and outputs will be logged to $LOG_FILE"

# Function to check for errors in command output

Getting started with configuration management

The following code example shows how to:

- Create an Amazon S3 bucket
- Create an Amazon SNS topic
- Create an IAM role for Config
- Set up the Config configuration recorder
- Set up the Config delivery channel
- Start the configuration recorder
- Verify the Config setup

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Config Setup Script (v2)
# This script sets up AWS Config with the AWS CLI

# Error handling
set -e
LOGFILE="aws-config-setup-v2.log"
touch $LOGFILE
exec > >(tee -a $LOGFILE)
exec 2>&1

# Function to handle errors
handle_error() {
    echo "ERROR: An error occurred at line $1"
```

```
    echo "Attempting to clean up resources..."
    cleanup_resources
    exit 1
}

# Set trap for error handling
trap 'handle_error $LINENO' ERR

# Function to generate random identifier
generate_random_id() {

Getting started with managed kubernetes clusters

The following code example shows how to:

- Create a VPC for your EKS cluster
- Create IAM roles for your EKS cluster
- Create your EKS cluster
- Configure kubectl to communicate with your cluster
- Create a managed node group
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon EKS Cluster Creation Script (v2)
# This script creates an Amazon EKS cluster with a managed node group using the AWS
 CLI

# Set up logging
LOG_FILE="eks-cluster-creation-v2.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon EKS cluster creation script at $(date)"
echo "All commands and outputs will be logged to $LOG_FILE"

- UpdateKubeconfig
- Wait (CloudFormation)
- Wait (Amazon EKS)

Getting started with managed streaming

The following code example shows how to:

- Create an MSK cluster
- Create IAM permissions for MSK access
- Create a client machine
- Get bootstrap brokers
- Set up the client machine
- Create a topic and produce/consume data
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon MSK Getting Started Tutorial Script - Version 8
# This script automates the steps in the Amazon MSK Getting Started tutorial
# It creates an MSK cluster, sets up IAM permissions, creates a client machine,
# and configures the client to interact with the cluster

# Set up logging
LOG_FILE="msk_tutorial_$(date +%Y%m%d_%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting Amazon MSK Getting Started Tutorial Script - Version 8"

Getting started with push notifications

The following code example shows how to:

- Create an application
- Enable push notification channels
- Send a push notification
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS End User Messaging Push Getting Started Script
# This script creates an AWS End User Messaging Push application and demonstrates
# how to enable push notification channels and send a test message.
#
# Prerequisites:
# - AWS CLI installed and configured
# - Appropriate IAM permissions for Pinpoint operations
```

```
#
# Usage: ./aws-end-user-messaging-gs.sh [--auto-cleanup]

set -uo pipefail

# Security: Set secure umask for created files
umask 0077

# Set up logging
LOG_DIR="./aws-eump-logs"
mkdir -p "$LOG_DIR"
LOG_FILE="$LOG_DIR/aws-end-user-messaging-push-script-$(date +%Y%m%d-%H%M%S).log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting AWS End User Messaging Push setup script..."
echo "Logging to $LOG_FILE"
echo "Timestamp: $(date)"

Getting started with search and analytics engines

The following code example shows how to:

- Create an OpenSearch Service domain
- Upload data to your domain
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon OpenSearch Service Getting Started Script - Version 8 Fixed
# This script creates an OpenSearch domain, uploads data, searches documents, and
 cleans up resources
# Based on the tested and working 4-tutorial-final.md

# SECURITY IMPROVEMENTS IN THIS VERSION:
# 1. Removed hardcoded passwords - now generated securely
# 2. Improved access policy to use principle of least privilege
# 3. Added credential masking in logs
# 4. Removed credentials from command output
# 5. Added input validation for AWS region
# 6. Improved error handling and validation
# 7. Added secure temporary file handling
# 8. Removed unnecessary curl insecurity flags
# 9. Added better secret management practices
# 10. Improved resource tagging for better governance
```

```

  - GetCallerIdentity

Getting started with web application firewalls

The following code example shows how to:

- Create a web ACL
- Add a string match rule

- Add managed rules
- Configure logging
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS WAF Getting Started Script
# This script creates a Web ACL with a string match rule and AWS Managed Rules,
# associates it with a CloudFront distribution, and then cleans up all resources.

set -euo pipefail

# Security: Restrict file permissions

Moving hardcoded secrets to secure secret storage

The following code example shows how to:

- Create IAM roles

- Create a secret in Secrets Manager
- Update your application code
- Update the secret
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to move hardcoded secrets to AWS Secrets Manager
# This script demonstrates how to create IAM roles, store a secret in AWS Secrets
 Manager,
# and set up appropriate permissions

set -euo pipefail

# Set up logging
LOG_FILE="secrets_manager_tutorial.log"
exec > >(tee -a "$LOG_FILE") 2>&1

echo "Starting AWS Secrets Manager tutorial script at $(date)"

Setting up systems management

The following code example shows how to:

- Create IAM permissions for Systems Manager
- Create an IAM role for Systems Manager
- Configure Systems Manager
- Verify the setup
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Systems Manager Setup Script
# This script sets up AWS Systems Manager for a single account and region
#
# Version 17 fixes:
# 1. Added cloudformation.amazonaws.com to the IAM role trust policy
# 2. Systems Manager Quick Setup uses CloudFormation for deployments, so the role
 must trust CloudFormation service
```

```
# Initialize log file
LOG_FILE="ssm_setup_$(date +%Y%m%d_%H%M%S).log"
UNIQUE_ID=$(openssl rand -hex 4)

#!/bin/bash

# ECS EC2 Launch Type Tutorial Script - UPDATED VERSION
# This script demonstrates creating an ECS cluster, launching a container instance,
# registering a task definition, and creating a service using the EC2 launch type.
# Updated to match the tutorial draft with nginx web server and service creation.
#
```

```
# - UPDATED: Changed from sleep task to nginx web server with service

set -e  # Exit on any error

Setting up systems management

The following code example shows how to:

- Create IAM permissions for Systems Manager
- Create an IAM role for Systems Manager
- Configure Systems Manager
- Verify the setup
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# AWS Systems Manager Setup Script
# This script sets up AWS Systems Manager for a single account and region
#
# Version 17 fixes:
# 1. Added cloudformation.amazonaws.com to the IAM role trust policy
# 2. Systems Manager Quick Setup uses CloudFormation for deployments, so the role
 must trust CloudFormation service

# Initialize log file

Amazon Textract examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with Amazon Textract.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Getting started with document text extraction

The following code example shows how to:

- Create an S3 bucket
- Upload a document to S3
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Amazon Textract Getting Started Tutorial Script
# This script demonstrates how to use Amazon Textract to analyze document text

set -euo pipefail

# Set up logging with restricted permissions
LOG_FILE="textract-tutorial.log"
touch "$LOG_FILE"
chmod 600 "$LOG_FILE"
exec > >(tee -a "$LOG_FILE") 2>&1

VPC Lattice examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with VPC Lattice.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Creating and managing a service networking mesh

The following code example shows how to:

- Create a service network
- Create a service
- List available VPCs
- List security groups for the selected VPC
- List service associations
- List VPC associations
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# VPC Lattice Service Network Tutorial Script
# This script demonstrates how to create and manage a VPC Lattice service network

WorkSpaces examples using AWS CLI with Bash script

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Bash script with WorkSpaces.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Creating and managing personal virtual desktops

The following code example shows how to:

- Verify WorkSpaces availability in your region
- List available WorkSpaces bundles
- Create a WorkSpace
- Check the status of your WorkSpace
- Clean up resources

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to create a WorkSpace in WorkSpaces Personal
# This script follows the workflow described in the AWS documentation
```

```
# https://docs.aws.amazon.com/workspaces/latest/adminguide/create-workspaces-
personal.html

# Set up logging

Security in the AWS CLI

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to AWS Command Line Interface, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using the AWS Command Line Interface (AWS CLI). The following topics show you how to configure the AWS CLI to meet your security and compliance objectives. You also learn how to use the AWS CLI to help you to monitor and secure your AWS resources.

Topics

- Data protection in the AWS CLI
- Identity and Access Management
- Compliance Validation for this AWS Product or Service
- Resilience for this AWS Product or Service
- Infrastructure Security for this AWS Product or Service
- Enforcing a minimum version of TLS for the AWS CLI

Data protection in the AWS CLI

The AWS shared responsibility model applies to data protection in AWS Command Line Interface. As described in this model, AWS is responsible for protecting the global infrastructure that runs

all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see Data Privacy FAQ. For information about data protection in Europe, see the General Data Protection Regulation (GDPR) Center.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with AWS CLI or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Data encryption

A key feature of any secure service is that information is encrypted when it is not being actively used.

Encryption at rest

By default, the AWS CLI does not itself store any customer data other than the credentials it needs to interact with the AWS services on the user's behalf.

When the user enables the optional `cli_history` feature, the AWS CLI stores complete command execution history, including command parameters and API request/response data in `~/.aws/cli/history/history.db`. You can disable this feature at any time by setting `cli_history = disabled` in the AWS CLI configuration. To store history in a different location, set the `AWS_CLI_HISTORY_FILE` environment variable.

If you use the AWS CLI to invoke an AWS service that transmits customer data to your local computer for storage, then refer to the Security & Compliance chapter in that service's User Guide for information on how that data is stored, protected, and encrypted.

Encryption in transit

By default, all data transmitted from the client computer running the AWS CLI and AWS service endpoints is encrypted by sending everything through a HTTPS/TLS connection.

You don't need to do anything to enable the use of HTTPS/TLS. It is always enabled unless you explicitly disable it for an individual command by using the `--no-verify-ssl` command line option.

Identity and Access Management

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use AWS resources. IAM is an AWS service that you can use with no additional charge.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How AWS services work with IAM
- Troubleshooting AWS identity and access

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in AWS.

Service user – If you use AWS services to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more AWS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in AWS, see Troubleshooting AWS identity and access or the user guide of the AWS service you are using.

Service administrator – If you're in charge of AWS resources at your company, you probably have full access to AWS. It's your job to determine which AWS features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with AWS, see the user guide of the AWS service you are using.

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to AWS. To view example AWS identity-based policies that you can use in IAM, see the user guide of the AWS service you are using.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you

don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access AWS using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity with specific permissions that provides temporary credentials. You can assume a role by switching from a user to an IAM role (console) or by calling an AWS CLI or AWS API operation. For more information, see Methods to assume a role in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For

more information about JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must specify a principal in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see Service control policies in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How AWS services work with IAM

To get a high-level view of how AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

To learn how to use a specific AWS service with IAM, see the security section of the relevant service's User Guide.

Troubleshooting AWS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with AWS and IAM.

Topics

- I am not authorized to perform an action in AWS

- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my AWS resources

I am not authorized to perform an action in AWS

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `awes:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 awes:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *`my-example-widget`* resource by using the `awes:`*`GetWidget`* action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to AWS.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in AWS. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my AWS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether AWS supports these features, see How AWS services work with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

Compliance Validation for this AWS Product or Service

Our new AWS sign-up experience is not designed for regulated workloads. If you're using our new AWS sign-up experience, but you want to use AWS for regulated workloads, you can sign up for AWS (advanced) or activate advanced features for your AWS environment.

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. For more

information about your compliance responsibility when using AWS services, see AWS Security Documentation.

This AWS product or service follows the shared responsibility model through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the AWS service security documentation page and AWS services that are in scope of AWS compliance efforts by compliance program.

Resilience for this AWS Product or Service

The AWS global infrastructure is built around AWS Regions and Availability Zones.

AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking.

With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

This AWS product or service follows the shared responsibility model through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the AWS service security documentation page and AWS services that are in scope of AWS compliance efforts by compliance program.

Infrastructure Security for this AWS Product or Service

This AWS product or service uses managed services, and therefore is protected by the AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access this AWS Product or Service through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.

- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

This AWS product or service follows the shared responsibility model through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the AWS service security documentation page and AWS services that are in scope of AWS compliance efforts by compliance program.

Enforcing a minimum version of TLS for the AWS CLI

When using the AWS Command Line Interface (AWS CLI), the Transport Layer Security (TLS) protocol plays a crucial role in securing communication between the AWS CLI and AWS services. To add increased security when communicating with AWS services, you should use TLS 1.2 or later. TLS 1.3 is a prerequisite to enable post-quantum cryptography, which may require additional actions or configurations. To learn more, see Enabling hybrid post-quantum TLS.

AWS CLI version 2 uses an internal Python script that's compiled to use a minimum of TLS 1.2 when the service it's talking to supports it. As long as you use version 2 of the AWS CLI, no further steps are needed to enforce this minimum. Additionally, to enforce a minimum of TLS 1.3 on Linux, you can install AWS CLI version `2.34.54` or higher using the AWS CLI installer for Linux. To ensure you're getting increased security, be sure to update to a recent version of the AWS CLI.

The AWS CLI and AWS service can exchange data securely, with the TLS protocol providing encryption, authentication, and data integrity. By leveraging the TLS protocol, the AWS CLI ensures that your interactions with AWS services are protected from unauthorized access and data breaches, enhancing the overall security of your AWS ecosystem.

The AWS shared responsibility model applies to data protection in AWS Command Line Interface. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS services. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data protection, see the section called “Data Protection”.

Migration guide for the AWS CLI version 2

This section contains instructions for updating the AWS CLI version 1 to AWS CLI version 2. The AWS CLI version 2 builds on AWS CLI version 1 and includes features and enhancements based on community feedback. The AWS CLI version 2 is the most recent major version of the AWS CLI and supports all of the latest features. Some features that were introduced in version 2 are not backported to version 1 and you must upgrade to access those features.

To prevent unexpected issues, before you migrate to version 2, learn about the differences between the versions. The AWS CLI version 2 includes new features and changes that might require you to update your scripts or commands for backwards compatibility.

AWS CLI versions 1 and 2 use the same `aws` command name. If you have both versions installed, your computer uses the first one found in your search path. This could result in your `aws` command name calling your old AWS CLI version, even when you have the new one installed.

To update to the AWS CLI version 2, follow one of the below instructions:

- If you previously installed AWS CLI version 1, follow the instructions in the section called "Migration instructions".
- If you have not previously installed AWS CLI version 1, follow the instructions in *Get started*.

Using AWS CLI Migration Tools to Mitigate Breakage

There are changes in behavior between AWS CLI version 1 and AWS CLI version 2 that might require you to update your scripts or commands. Upgrading to AWS CLI version 2 without verifying that your existing scripts are safely migrated risks encountering unexpected effects when running the scripts with AWS CLI version 2, such as making unintended changes to the resources on your AWS accounts.

There are two AWS-owned tools that you can use to guide your migration. Regardless of which tool you use, we recommend that you reference Breaking changes between AWS CLI version 1 and AWS CLI version 2 in the New features and changes in the AWS CLI version 2 guide.

Upgrade Debug Mode

Upgrade debug mode is a feature in AWS CLI version 1 that is available in versions `1.44.0` and higher. When this feature is enabled, each AWS CLI command that you execute is checked to

determine if it is likely to have different behavior in AWS CLI version 2, assuming the execution environment stays the same. If an executed command would have different behavior in AWS CLI version 2, a warning will be shown alongside the command output with suggested actions that can be taken to preserve AWS CLI version 1 behavior in AWS CLI version 2.

The main reason to use upgrade debug mode to guide your migration is that it has high coverage for detecting whether commands will face a change of behavior. In total, 15 out of the 16 breaking changes described in Breaking changes between AWS CLI version 1 and AWS CLI version 2 can be detected with upgrade debug mode—see Limitations in Using upgrade debug mode to upgrade AWS CLI version 1 to AWS CLI version 2 for the limitations of this feature. On the other hand, the main downside of using upgrade debug mode is that its output is only relevant within its execution environment; if any AWS CLI configuration settings change in the environment after migrating to AWS CLI version 2, breaking changes may still occur, and you should re-verify using upgrade debug mode in the updated environment.

AWS CLI v1-to-v2 Migration Tool

The AWS CLI v1-to-v2 Migration Tool is a standalone tool that can be used with Python 3.9 and higher. This tool is a static linter that runs independently of the AWS CLI. It lints bash scripts containing AWS CLI version 1 commands that may have different behavior in AWS CLI version 2. For most commands that it detects as likely to have different behavior in AWS CLI version 2, it can automatically update the command within the script to preserve AWS CLI version 1 behavior in AWS CLI version 2.

The main reason to use the AWS CLI v1-to-v2 Migration Tool to guide your migration is that it can automatically update your scripts to preserve AWS CLI version 1 behavior in AWS CLI version 2, saving you time and effort in making the updates yourself. On the other hand, the main downside to using the migration tool is that it has lower coverage for detecting whether commands will face a change of behavior. Being a static tool, it does not check for changes in behavior that is determined at runtime.

Choosing Between Upgrade Debug Mode and AWS CLI v1-to-v2 Migration Tool

The following table highlights the main differences between upgrade debug mode and the AWS CLI v1-to-v2 Migration Tool, and can be used to help guide you to choosing the right tool for your use case.

Upgrade debug mode	AWS CLI v1-to-v2 Migration Tool
Detects 15 out of the 16 breaking changes between AWS CLI version 1 and AWS CLI version 2.	Detects 7 out of the 16 breaking changes between AWS CLI version 1 and AWS CLI version 2.
Compatible with any terminal program that can run the AWS CLI.	Only supports linting bash scripts.
Requires AWS CLI version 1, version `1.44.0` or higher.	Runs independently of the AWS CLI; it does not require the AWS CLI to be installed.
Manual fixes must be made to preserve AWS CLI version 1 behavior in AWS CLI version 2.	Automatically fixes most AWS CLI version 1 commands that it detects as likely to have different behavior in AWS CLI version 2.
Detections and suggested fixes are only relevant to the execution environment (i.e. AWS CLI configuration) that it is executed in.	Detections and suggested fixes are independe nt of the environment.
Requires executing each AWS CLI command under test for change of behavior.	Does not require executing any AWS CLI commands. Only needs to be executed once per bash script.
Has exactly 5 known cases where it will output false positive detections.	Has exactly 3 known cases where it will output false positive detections.

The following table shows which of the Breaking changes between AWS CLI version 1 and AWS CLI version 2 are supported in each of the two migration tools.

Breaking change	Detected by upgrade debug mode	Detected by AWS CLI v1-to-v2 Migration Tool
Environment variable added to set text file encoding	Yes	No

Breaking change	Detected by upgrade debug mode	Detected by AWS CLI v1-to-v2 Migration Tool
Binary parameters are passed as base64-encoded strings by default	Yes	Yes
Improved Amazon S3 handling of file properties and tags for multipart copies	Yes	Yes
No automatic retrieval of `http://` or `https://` URLs for parameters	Yes	No
Pager used for all output by default	Yes	Yes
Timestamp output values are standardized to ISO 8601 format	Yes	No
Improved handling of CloudFormation deployments that result in no changes	Yes	Yes
Changed default behavior for Regional Amazon S3 endpoint for `us-east-1` Region	Yes	No
Changed default behavior for Regional AWS STS endpoints	Yes	No
`ecr get-login` removed and replaced with `ecr get-login-password`	Yes	Yes
AWS CLI version 2 support for plugins is changing	Yes	No

Breaking change	Detected by upgrade debug mode	Detected by AWS CLI v1-to-v2 Migration Tool
Hidden alias support removed	Yes	Yes
The `api_versions` configuration file setting is not supported	Yes	No
AWS CLI version 2 uses only Signature v4 to authenticate Amazon S3 requests	Yes	No
AWS CLI version 2 is more consistent with paging parameters	Yes	Yes
AWS CLI version 2 provides more consistent return codes across all commands	No	No
AWS CLI version 2 uses CRC64NVME checksums by default for high-level Amazon S3 uploads	Yes	No

Additional topics in this section

- the section called “New features and changes”
- the section called “Migration instructions”
- the section called “Using upgrade debug mode”
- the section called “Using AWS CLI v1-to-v2 Migration Tool”

New features and changes in the AWS CLI version 2

This topic describes new features and changes in behavior between AWS CLI version 1 and AWS CLI version 2. These changes might require you to update your scripts or commands to get the same behavior in version 2 as you did in version 1.

Topics

- AWS CLI version 2 new features
- Breaking changes between AWS CLI version 1 and AWS CLI version 2

AWS CLI version 2 new features

The AWS CLI version 2 is the most recent major version of the AWS CLI and supports all of the latest features. Some features introduced in version 2 are not backported to version 1 and you must upgrade to access those features. These features include the following:

Python interpreter not needed

The AWS CLI version 2 doesn't need a separate install of Python. It includes an embedded version.

Wizards

You can use a wizard with the AWS CLI version 2. The wizard guides you through constructing certain commands.

IAM Identity Center authentication

If your organization uses AWS IAM Identity Center (IAM Identity Center), your users can sign in to Active Directory, a built-in IAM Identity Center directory, or another IdP connected to IAM Identity Center. Then, they are mapped to an AWS Identity and Access Management (IAM) role that allows you to run AWS CLI commands.

Auto-prompt

When enabled, the AWS CLI version 2 can prompt you for commands, parameters, and resources when you run an `aws` command.

Running the official Amazon ECR Public or Docker images for the AWS CLI

The official Docker image for the AWS CLI provides isolation, portability, and security that AWS directly supports and maintains. This way, you can use the AWS CLI version 2 in a container-based environment without having to manage the installation yourself.

Client-side pager

The AWS CLI version 2 provides the use of a client-side pager program for output. By default, this feature is turned on and returns all output through your operating system's default pager program.

`aws configure import`

Import `.csv` credentials generated from the AWS Management Console. A `.csv` file is imported with the profile name matching the IAM user name.

`aws configure list-profiles`

Lists the names of all profiles you have configured.

the section called "YAML stream output format"

The `yaml` and `yaml-stream` format takes advantage of the YAML format while providing more responsive viewing of large datasets by streaming the data to you. You can start viewing and using YAML data before the entire query downloads.

New high-level ddb commands for DynamoDB

The AWS CLI version 2 has the high-level Amazon DynamoDB commands `ddb put` and `ddb select`. These commands provide a simplified interface for putting items in DynamoDB tables and searching in a DynamoDB table or index.

`aws logs tail`

The AWS CLI version 2 has a custom `aws logs tail` command that tails the logs for an Amazon CloudWatch Logs group. By default, the command returns logs from all associated CloudWatch Logs streams during the past ten minutes.

Added metadata support for high-level `s3` commands

The AWS CLI version 2 adds the `--copy-props` parameter to the high-level `s3` commands. With this parameter, you can configure additional metadata and tags for Amazon Simple Storage Service (Amazon S3).

AWS_REGION

The AWS CLI version 2 has an AWS SDK-compatible environment variable called `AWS_REGION`. This variable specifies the AWS Region to send requests to. It overrides the `AWS_DEFAULT_REGION` environment variable, which is only applicable in the AWS CLI.

Breaking changes between AWS CLI version 1 and AWS CLI version 2

This sections describes all of the changes in behavior between AWS CLI version 1 and AWS CLI version 2. These changes might require you to update your scripts or commands to get the same behavior in version 2 as you did in version 1.

Topics

- Environment variable added to set text file encoding
- Binary parameters are passed as base64-encoded strings by default
- Improved Amazon S3 handling of file properties and tags for multipart copies
- No automatic retrieval of http:// or https:// URLs for parameters
- Pager used for all output by default
- Timestamp output values are standardized to ISO 8601 format
- Improved handling of CloudFormation deployments that result in no changes
- Changed default behavior for Regional Amazon S3 endpoint for us-east-1 Region
- Changed default behavior for Regional AWS STS endpoints
- ecr get-login removed and replaced with ecr get-login-password
- AWS CLI version 2 support for plugins is changing
- Hidden alias support removed
- The api_versions configuration file setting is not supported
- AWS CLI version 2 uses only Signature v4 to authenticate Amazon S3 requests
- AWS CLI version 2 is more consistent with paging parameters
- AWS CLI version 2 provides more consistent return codes across all commands
- AWS CLI version 2 uses CRC64NVME checksums by default for high-level Amazon S3 uploads

Environment variable added to set text file encoding

By default, text files for the section called "Blob" use the same encoding as the installed locale. Because the AWS CLI version 2 uses an embedded version of Python, the `PYTHONUTF8` and `PYTHONIOENCODING` environment variables are not supported. To set encoding for text files to be different from the locale, use the `AWS_CLI_FILE_ENCODING` environment variable. The following example sets the AWS CLI to open text files using `UTF-8` on Windows.

```
AWS_CLI_FILE_ENCODING=UTF-8
```

For more information, see Configuring environment variables for the AWS CLI .

Binary parameters are passed as base64-encoded strings by default

In the AWS CLI, some commands required base64-encoded strings, while others required UTF-8-encoded byte strings. In the AWS CLI version 1, passing data between two encoded string types often required some intermediate processing. The AWS CLI version 2 makes handling binary parameters more consistent, which helps pass values from one command to another more reliably.

By default, the AWS CLI version 2 passes all binary input and binary output parameters as the base64-encoded string `blobs` (binary large object). For more information, see the section called "Blob".

To revert to the AWS CLI version 1 behavior, use the `cli_binary_format` file configuration or the `--cli-binary-format` parameter.

Improved Amazon S3 handling of file properties and tags for multipart copies

When you use the AWS CLI version 1 commands in the `aws s3` namespace to copy a file from one S3 bucket location to another, and that operation uses multipart copy, no file properties from the source object are copied to the destination object.

By default, the corresponding commands in the AWS CLI version 2 transfer all tags and some of the properties from the source to the destination copy. Compared to the AWS CLI version 1, this can result in more AWS API calls being made to the Amazon S3 endpoint. To change the default behavior for `s3` commands in AWS CLI version 2 , use the `--copy-props` parameter.

For more information, see the section called "File properties and tags in multipart copies".

No automatic retrieval of `http://` or `https://` URLs for parameters

The AWS CLI version 2 does not perform a `GET` operation when a parameter value begins with `http://` or `https://`, and does not use the returned content as the parameter value. As a result, the associated command line option `cli_follow_urlparam` is removed from the AWS CLI version 2.

If you need to retrieve a URL and pass the URL contents into a parameter value, we recommend that you use `curl` or a similar tool to download the contents of the URL to a local file. Then, use the `file://` syntax to read the contents of that file and use it as the parameter value.

For example, the following command no longer tries to retrieve the contents of the page found at `http://www.example.com` and pass those contents as the parameter. Instead, it passes the literal text string `https://example.com` as the parameter.

```
$ aws ssm put-parameter \
    --value http://www.example.com \
    --name prod.microservice1.db.secret \
    --type String 2
```

If you need to retrieve and use the contents of a web URL as a parameter, you can do the following in version 2.

```
$ curl https://my.example.com/mypolicyfile.json -o mypolicyfile.json
$ aws iam put-role-policy \
    --policy-document file://./mypolicyfile.json \
    --role-name MyRole \
    --policy-name MyReadOnlyPolicy
```

In the preceding example, the `-o` parameter tells `curl` to save the file in the current folder with the same name as the source file. The second command retrieves the content of that downloaded file and passes the content as the value of `--policy-document`.

Pager used for all output by default

By default, the AWS CLI version 2 returns all output through your operating system's default pager program. This program is the `less` program on Linux or macOS, and the `more` program on Windows. This can help you navigate a large amount of output from a service by displaying that output one page at a time.

You can configure the AWS CLI version 2 to use a different paging program or none at all. For more information, see the section called “Client-side pager”.

Timestamp output values are standardized to ISO 8601 format

By default, the AWS CLI version 2 returns all timestamp response values in the ISO 8601 format. In AWS CLI version 1, commands returned timestamp values in whatever format was returned by the HTTP API response, which could vary from service to service.

To see timestamps in the format returned by the HTTP API response, use the `wire` value in your `config` file. For more information, see `cli_timestamp_format`.

Improved handling of CloudFormation deployments that result in no changes

By default in the AWS CLI version 1, if you deploy a CloudFormation template that results in no changes, the AWS CLI returns a failed error code. This causes problems if you don't consider that to be an error and you want your script to continue. You can work around this in the AWS CLI version 1 by adding the flag `--no-fail-on-empty-changeset`, which returns `0`.

Since this is a common use case, the AWS CLI version 2 defaults to returning a successful exit code of `0` when there is no change caused by a deployment and the operation returns an empty changeset.

To revert to the original behavior, add the flag `--fail-on-empty-changeset`.

Changed default behavior for Regional Amazon S3 endpoint for `us-east-1` Region

When you configure theAWS CLI version 1 to use the `us-east-1` Region, the AWS CLI uses the global `s3.amazonaws.com` endpoint that is physically hosted in the `us-east-1` Region. The AWS CLI version 2 uses the true Regional endpoint `s3.us-east-1.amazonaws.com` when that Region is specified. To force the AWS CLI version 2 to use the global endpoint, you can set the Region for a command to `aws-global`.

Changed default behavior for Regional AWS STS endpoints

By default, the AWS CLI version 2 sends all AWS Security Token Service (AWS STS) API requests to the Regional endpoint for the currently configured AWS Region.

By default, any release before `1.42.0` for AWS CLI version 1 sends AWS STS requests to the global AWS STS endpoint. You can control this default behavior in version 1 by using the `sts_regional_endpoints` setting.

Any releases on or after `1.42.0` uses the Regional endpoint as the default, if you are migrating to AWS CLI version 2 from these newer releases this behavior remains unchanged.

`ecr get-login` removed and replaced with `ecr get-login-password`

The AWS CLI version 2 replaces the command `aws ecr get-login` with the `aws ecr get-login-password` command that improves automated integration with container authentication.

The `aws ecr get-login-password` command reduces the risk of exposing your credentials in the process list, shell history, or other log files. It also improves compatibility with the `docker login` command for better automation.

The `aws ecr get-login-password` command is available in the AWS CLI version 1.17.10 and later, and the AWS CLI version 2. The earlier `aws ecr get-login` command is still available in the AWS CLI version 1 for backward compatibility.

With the `aws ecr get-login-password` command, you can replace the following code that retrieves a password.

```
$ (aws ecr get-login --no-include-email)
```

To reduce the risk of exposing the password to the shell history or logs, use the following example command instead. In this example, the password is piped directly to the `docker login` command, where it is assigned to the password parameter by the `--password-stdin` option.

```
$ aws ecr get-login-password | docker login --username AWS --password-stdin MY-
REGISTRY-URL
```

For more information, see `aws ecr get-login-password` in the *AWS CLI version 2 Reference Guide*.

AWS CLI version 2 support for plugins is changing

Plugin support in the AWS CLI version 2 is completely provisional and is intended to help users migrate from AWS CLI version 1 until a stable, updated plugin interface is released. There are no guarantees that a particular plugin or even the AWS CLI plugin interface will be supported in future

versions of the AWS CLI version 2. If you rely on plugins, be sure to lock into a particular version of the AWS CLI and test the functionality of your plugin when you do upgrade.

To enable plugin support, create a `[plugins]` section in your `~/.aws/config`.

```
[plugins]
cli_legacy_plugin_path = <path-to-plugins>/python3.7/site-packages
<plugin-name> = <plugin-module>
```

In the `[plugins]` section, define the `cli_legacy_plugin_path` variable and set its value to the Python site packages path where your plugin module is. Then, you can configure a plugin by providing a name for the plugin (`plugin-name`) and the file name of the Python module (`plugin-module`) that contains the source code for your plugin. The AWS CLI loads each plugin by importing its `plugin-module` and calling its `awscli_initialize` function.

Hidden alias support removed

AWS CLI version 2 no longer supports the following hidden aliases that were supported in version 1.

In the following table, the first column displays the service, command, and parameter that work in all versions, including the AWS CLI version 2. The second column displays the alias that no longer works in the AWS CLI version 2.

Working service, command, and parameter	Obsolete alias
cognito-identity create-identity-pool open-id-connect-provider-arns	open-id-connect-provider-ar-ns
storagegateway describe-tapes tape-arns	tape-ar-ns
storagegateway.describe-tape-archives.tape-arns	tape-ar-ns
storagegateway.describe-vtl-devices.vtl-device-arns	vtl-device-ar-ns
storagegateway.describe-cached-iscsi-volumes.volume-arns	volume-ar-ns
storagegateway.describe-stored-iscsi-volumes.volume-arns	volume-ar-ns
route53domains.view-billing.start-time	start

Working service, command, and parameter	Obsolete alias
deploy.create-deployment-group.ec2-tag-set	ec-2-tag-set
deploy.list-application-revisions.s3-bucket	s-3-bucket
deploy.list-application-revisions.s3-key-prefix	s-3-key-prefix
deploy.update-deployment-group.ec2-tag-set	ec-2-tag-set
iam.enable-mfa-device.authentication-code1	authentication-code-1
iam.enable-mfa-device.authentication-code2	authentication-code-2
iam.resync-mfa-device.authentication-code1	authentication-code-1
iam.resync-mfa-device.authentication-code2	authentication-code-2
importexport.get-shipping-label.street1	street-1
importexport.get-shipping-label.street2	street-2
importexport.get-shipping-label.street3	street-3
lambda.publish-version.code-sha256	code-sha-256
lightsail.import-key-pair.public-key-base64	public-key-base-64
opsworks.register-volume.ec2-volume-id	ec-2-volume-id

The `api_versions` configuration file setting is not supported

The AWS CLI version 2 doesn't support calling earlier versions of AWS service APIs by using the `api_versions` configuration file setting. All AWS CLI commands now call the latest version of the service APIs that are currently supported by the endpoint.

AWS CLI version 2 uses only Signature v4 to authenticate Amazon S3 requests

The AWS CLI version 2 doesn't support earlier signature algorithms to cryptographically authenticate service requests sent to Amazon S3 endpoints. This signing happens automatically with every Amazon S3 request and only the Signature Version 4 Signing Process is supported. You

can't configure the signature version. All Amazon S3 bucket presigned URLs now use only SigV4 and have a maximum expiration duration of one week.

AWS CLI version 2 is more consistent with paging parameters

In the AWS CLI version 1, if you specify pagination parameters on the command line, then automatic pagination is turned off as expected. However, when you specify pagination parameters by using a file with the `--cli-input-json` parameter, automatic pagination was not turned off, which could result in unexpected output. The AWS CLI version 2 turns off automatic pagination regardless of how you provide the parameters.

AWS CLI version 2 provides more consistent return codes across all commands

The AWS CLI version 2 is more consistent across all commands and properly returns an appropriate exit code compared to the AWS CLI version 1. We also added exit codes 252, 253, and 254. For more information on exit codes, see the section called “Return Codes”.

If you have a dependency on how the AWS CLI version 1 uses return code values, we recommend checking the exit codes to make sure that you're getting the values you expect.

AWS CLI version 2 uses CRC64NVME checksums by default for high-level Amazon S3 uploads

In AWS CLI version 1 versions `1.37.0` or later, for commands in the `aws s3` namespace that upload a file to an Amazon S3 bucket, the AWS CLI version 1 will automatically calculate a Cyclic Redundancy Check 32 (CRC32) checksum by default and include it in the request. Amazon S3 will store this checksum in the object metadata.

By default, the corresponding commands in AWS CLI version 2 versions `2.23.0` or later, will instead use Cyclic Redundancy Check 64 (CRC64NVME) checksums. To change the checksum algorithm for `s3` commands, use the `--checksum-algorithm` parameter.

AWS CLI version 1 versions prior to `1.37.0` compute MD5 or SHA256 checksums for data integrity during uploads, but neither gets stored in the object metadata.

For more information, see AWS CLI version 2 Amazon S3 FAQ .

Installing AWS CLI version 2 from AWS CLI version 1

This topic provides instructions for migrating from AWS CLI version 1 to AWS CLI version 2.

AWS CLI versions 1 and 2 use the same `aws` command name. If you have both versions installed, your computer uses the first one found in your search path. If you previously installed AWS CLI version 1, we recommend that you do one of the following to use AWS CLI version 2:

- **Recommended** – Uninstall AWS CLI version 1 and use only AWS CLI version 2.
- To have both version installed, use your operating system's ability to create a symbolic link (symlink) or alias with a different name for one of the two `aws` commands.

For information on breaking changes between version 1 and version 2, see the section called "New features and changes".

Replacing version 1 with version 2

Perform the following steps to replace AWS CLI version 1 with AWS CLI version 2.

To replace AWS CLI version 1 with AWS CLI version 2

1. Prepare any existing scripts you have for the migration by confirming any breaking changes between version 1 and version 2 in the section called "New features and changes". You can use the upgrade debug mode feature to guide your preparation by following the instructions in the section called "Using upgrade debug mode".
2. Uninstall the AWS CLI version 1 by following the uninstall instructions for your operating system in Installing, updating, and uninstalling the AWS CLI version 1.
3. Confirm that the AWS CLI is completely uninstalled by using the following command.

   ```
   $ aws --version
   ```

   Complete one of the following based on the output:

   - **No version returned:** You've successfully uninstalled the AWS CLI version 1 and can proceed to the next step.
   - **A version is returned:** You still have an install of the AWS CLI version 1. For troubleshooting steps, see the section called "The `aws --version` command returns a version after uninstalling the AWS CLI". Perform troubleshooting steps until no version output is received.
4. Install the AWS CLI version 2 by following the appropriate install instructions for your operating system in Installing or updating to the latest version of the AWS CLI.

Side-by-side install

To have both versions installed, use your operating system's ability to create a symbolic link (symlink) or alias with a different name for one of the two `aws` commands.

1. Install the AWS CLI version 2 by following the appropriate install instructions for your operating system in Installing or updating to the latest version of the AWS CLI.
2. Use your operating system's ability to create a symlink or alias with a different name for one of the two `aws` commands, such as using *`aws2`* for AWS CLI version 2. The following are symlink examples for AWS CLI version 2. Replace the *PATH* with your install location.

   Linux and macOS

   You can use a symbolic link or alias on Linux and macOS.

   ```
   $ alias aws2='PATH'
   ```

   Windows command prompt

   DOSKEY on Windows.

   ```
   C:\> doskey aws2=PATH
   ```

Using upgrade debug mode to upgrade AWS CLI version 1 to AWS CLI version 2

This topic describes the upgrade debug mode in AWS CLI version 1.

We recommend that users of AWS CLI version 1 upgrade to AWS CLI version 2 to access new features and enhanced performance. There are changes in behavior between AWS CLI version 1 and AWS CLI version 2 that might require you to update your scripts or commands to get the same behavior. The upgrade debug mode in AWS CLI version 1 outputs warnings when you use features that have different behavior in AWS CLI version 2. This feature improves the upgrade experience by automatically detecting which of your AWS CLI version 1 commands need to be modified before upgrading to AWS CLI version 2 to prevent unexpected issues.

For more details, see Breaking changes between AWS CLI version 1 and AWS CLI version 2 in New features and changes in the AWS CLI version 2.

Prerequisites

The upgrade debug mode feature was introduced to the AWS CLI in version `1.44.0`.

Using AWS CLI version 1, run `aws --version`, and verify that the AWS CLI version is `1.44.0` or higher.

If the version is less than `1.44.0`, see Installing, updating, and uninstalling the AWS CLI.

How it works

If enabled, the upgrade debug mode detects usage of features that were updated with breaking changes in AWS CLI version 2. If you use a command or feature listed in our Breaking changes between AWS CLI version 1 and AWS CLI version 2 after upgrading to AWS CLI version 2, a warning will be shown in the output. Breaking change detection is based on the command used, the arguments supplied, the execution environment (e.g. environment variables, configuration settings, etc.), and for a few cases, the content or configuration of resources in the AWS account being used.

The warnings describe actions to prevent unexpected issues of upgrading to AWS CLI version 2. After making the changes recommended by a warning message, you can confirm the command has been updated successfully by re-running the command to verify the warning is no longer shown. Warnings being resolved signals that the command is no longer likely to experience the breaking change described upon upgrading to AWS CLI version 2.

The following example demonstrates what these warnings look like. This command demonstrates an example warning. All warning text starts with "AWS CLI V2 UPGRADE WARNING," followed by the specific warning message. In this case, a warning is output because the command relies on the AWS CLI to retrieve the contents of the URL and use the contents as the `--template-body` parameter value, which was a feature removed in AWS CLI version 2.

```
$ aws cloudformation create-stack \
  --stack-name "stack012345" \
  --template-body "https://s3.amazonaws.com/amzn-s3-demo-bucket/template.json"

AWS CLI v2 UPGRADE WARNING: For input parameters that have a prefix of http:// or
https://, AWS CLI v2 will not automatically request the content of the URL for
the parameter, and the `cli_follow_urlparam` option has been removed. See
https://docs.aws.amazon.com/cli/latest/userguide/cliv2-migration-changes.html#cliv2-
migration-paramfile.
```

The following table of all breaking changes, and how to avoid facing a breaking change in AWS CLI version 2. Remediation actions that resolve the warnings in debug mode are in bold.

Breaking change	On v1, migrate to v2 behavior	On v2, retain v1 behavior
Environment variable added to set text file encoding	**Unset the `PYTHONUTF8` and `PYTHONIOENCODING` environment variables.**	**Set the `AWS_CLI_FILE_ENCODING` environment variable to the encoding specified in v1.**
Binary parameters are passed as base64-encoded strings by default	Encode the value of the parameter with base64. If the parameter is being loaded from a file, encode the file contents with base64.	**Set the `cli_binary_format` setting to `raw-in-base64-out` .**
Improved Amazon S3 handling of file properties and tags for multipart copies	N/A. Cannot migrate to version 2 behavior in version 1.	Use the `--copy-props none` parameter.
No automatic retrieval of `http://` or `https://` URLs for parameters	**Use curl (or alternative tools) to download the contents of the URLs to a local file. Then, load the file contents to the parameter with file://. Alternatively, configure `cli_follow_urlparam` to false to specify the raw URL as the paramater value.**	N/A. Impossible to retain version 1 behavior in version 2.
Pager used for all output by default	N/A. Cannot migrate to version 2 behavior in version 1.	**Set the `cli_pager` setting or `AWS_PAGER` variable to an empty string.**

Breaking change	On v1, migrate to v2 behavior	On v2, retain v1 behavior
Timestamp output values are standardized to ISO 8601 format	**Set the `cli_timestamp_format` setting to `iso8601`.**	**Set the `cli_timestamp_format` setting to `wire`.**
Improved handling of CloudFormation deployments that result in no changes	**Use the `--no-fail-on-empty-changeset` parameter.**	Use the `--fail-on-empty-changeset` parameter.
Changed default behavior for Regional Amazon S3 endpoint for `us-east-1` Region	**Set the `AWS_ENDPOINT_URL_S3` environment variable or the `--endpoint-url` command line option to the us-east-1 regional URL.**	**Use the `--region aws-global` command line option.**
`ecr get-login` removed and replaced with `ecr get-login-password`	**(1.17.10 or later) Use `ecr get-login` removed and replaced with `ecr get-login-password` and pipe the output into a docker command.**	N/A. Impossible to retain version 1 behavior in version 2.
AWS CLI version 2 support for plugins is changing	N/A. Cannot migrate to version 2 behavior in version 1.	Configure the cli_legacy_plugin_path to the `[plugins]` section of the configuration file. Test plugins in version 2, lock your version 2 version, and test your plugins each time you upgrade.

Breaking change	On v1, migrate to v2 behavior	On v2, retain v1 behavior
Hidden alias support removed	**Switch from using the obsolete hidden alias to Hidden alias support removed that works in all versions.**	N/A. Impossible to retain version 1 behavior in version 2.
The `api_versions` configuration file setting is not supported	**Migrate and test your usage of older API versions to the latest API version, and remove api_versions from your configuration settings.**	N/A. Impossible to retain version 1 behavior in version 2.
AWS CLI version 2 uses only Signature v4 to authenticate Amazon S3 requests	**Specify the Signature Version to version 4 (see Specifying the Signature Version in request authentication).**	N/A. Impossible to retain version 1 behavior in version 2.
AWS CLI version 2 is more consistent with paging parameters	**Move the pagination parameters in the input JSON parameter to the command itself.**	**Remove the pagination parameters from the input JSON parameter.**
AWS CLI version 2 provides more consistent return codes across all commands	N/A. Cannot migrate to version 2 behavior in version 1.	N/A. Impossible to retain version 1 behavior in version 2.
AWS CLI version 2 uses CRC64NVME checksums by default for high-level Amazon S3 uploads	(1.37.0 or later) Use `--checksum-algorithm CRC64NVME` command line option. (CRT required).	(2.23.0 or later) Use `--checksum-algorithm CRC32` command line option.

Limitations

We strongly recommend customers review our Breaking changes between AWS CLI version 1 and AWS CLI version 2.

Unsupported Breaking Change Detection

The upgrade debug mode feature supports every breaking change except that AWS CLI version 2 provides more consistent return codes across all commands. This mode cannot account for how you use the error codes returned by the AWS CLI downstream.

Conditional Breaking Change Detection

Detection of Timestamp output values are standardized to ISO 8601 format is the only case where detection depends on the state of the AWS account, and may be subject to breaking changes if the account resources are updated later. If no timestamps are included in the API response from the service, no detections will be made for this breaking change.

If you rely on the timestamp format returned by AWS CLI commands and have not already configured the AWS CLI to use ISO 8601, take extra precaution to ensure your processing of the timestamp will not break after upgrading to version 2.

Unresolvable Breaking Change Detection

Some warnings output by upgrade debug mode cannot be resolved by modifying the command or environment. The following cases are cases where warnings would always be output by upgrade debug mode as long as you use the corresponding feature:

- AWS CLI version 2 support for plugins is changing - if you rely on plugins in your configuration file, the upgrade debug mode will always output a warning that cannot be resolved. This mode cannot guarantee whether any of your plugins will work in AWS CLI version 2.
- Improved Amazon S3 handling of file properties and tags for multipart copies - if `aws s3` is used to perform a bucket-to-bucket Amazon Amazon S3 copy, the upgrade debug mode will always output a warning that cannot be resolved.

False detections

Warnings output by the upgrade debug mode do not guarantee that breaking changes will be faced after upgrading to AWS CLI v2. Below are cases where warnings would be output by upgrade debug mode, despite there being no breaking change introduced in AWS CLI v2:

- Environment variable added to set text file encoding - if the `PYTHONUTF8` or `PYTHONIOENCODING` environment variables are specified to set the text file encoding, and the specified encoding already matches the installed locale, the warning might be a false detection since debug mode does not check if the encoding matches the installed locale.
- Improved Amazon S3 handling of file properties and tags for multipart copies - if `aws s3` is used to perform a bucket-to-bucket Amazon Amazon S3 copy, and the copy is not multipart due to the source object being under the multipart threshold size, a false detection will be output.
- Timestamp output values are standardized to ISO 8601 format - if the cli_timestamp_format configuration setting is set to wire (default), and a timestamp in ISO 8601 format is returned by the service.
- Improved handling of CloudFormation deployments that result in no changes - if the `--fail-on-empty-changeset` flag is used with the `aws cloudformation deploy` command, and the resulting changeset is empty, a false detection will be output. Also, if the changeset is non-empty, and `--no-fail-on-empty-changeset` is not used, a false detection will be output.
- Changed default behavior for Regional Amazon S3 endpoint for `us-east-1` Region - if `aws s3` or `aws s3api` is used to perform an Amazon Amazon S3 operation, and the region is configured to `us-east-1`, and the `s3.us_east_1_regional_endpoint` configuration is not configured to regional, and the global Amazon S3 endpoint is used for the request due to the endpoint configuration settings, then the warning might be a false detection, since debug mode does not check configured endpoint settings.

Configure upgrade debug mode

You can enable or disable upgrade debug mode using the following methods, listed in order of precedence:

- Command line options enable or disable upgrade debug mode for a single command. Use `--v2-debug` to use upgrade debug mode.
- Environment variables use the AWS_CLI_UPGRADE_DEBUG_MODE variable.

Using AWS CLI v1-to-v2 Migration Tool to upgrade AWS CLI version 1 to AWS CLI version 2

This topic describes the AWS CLI v1-to-v2 Migration Tool.

We recommend that users of AWS CLI version 1 upgrade to AWS CLI version 2 to access new features and enhanced performance. There are changes in behavior between AWS CLI version 1 and AWS CLI version 2 that might require you to update your scripts or commands to get the same behavior. The AWS CLI v1-to-v2 Migration Tool analyzes bash scripts containing AWS CLI version 1 commands and detects usage of features that have been updated with breaking changes in AWS CLI version 2. Additionally, the tool can automatically modify your scripts to fix most issues that it detects. This tool improves the upgrade experience by automatically detecting and modifying AWS CLI version 1 commands in bash scripts to prevent unexpected issues when upgrading to version 2.

Compared to Upgrade Debug Mode, the AWS CLI v1-to-v2 Migration Tool is a standalone tool and does not require executing AWS CLI commands. For a thorough comparison between the Upgrade Debug Mode and the AWS CLI v1-to-v2 Migration Tool see Using AWS CLI Migration Tools to Mitigate Breakage in Migration guide for the AWS CLI version 2.

For more details, see Breaking changes between AWS CLI version 1 and AWS CLI version 2 in New features and changes in the AWS CLI version 2.

How it Works

The AWS CLI v1-to-v2 Migration Tool is a Python package capable of linting bash scripts that use AWS CLI version 1. Being a static linter, it does not depend on the version of AWS CLI version 1 that you may have installed on your machine. The linter is invoked through the command line, where the local file path to the bash script is supplied as a parameter.

The migration tool can also automatically produce a modified bash script that resolves most findings that it detects by modifying the AWS CLI version 1 commands used in the script. The migration tool modifies commands so that they are compatible with AWS version 2 and retains the behavior of version 1.

For some findings, the AWS CLI v1-to-v2 Migration Tool can detect them but not offer an automatic fix. In these cases, the migration tool flags them as detections that require manual review.

See Limitations for an exhaustive list of breaking changes and automatic fixes that the AWS CLI v1-to-v2 Migration Tool supports.

Prerequisites

Python

To use this tool, you must have Python 3.9 or later installed.

To verify that you have a correct Python version installed, run the following command in a terminal and confirm the output shows a Python version of at least 3.9.

```
$ python3 --version
```

If you have an older version of Python, or do not have Python installed, you can download a compatible version from the official Python download page.

pip

In addition to having a compatible version of Python installed, you must have `pip` installed.

To verify that `pip` is installed, run the following command:

```
$ python3 -m pip --version
```

If you have `pip` installed, you will see an output similar to the following:

```
pip 25.0.1 from ~/.local/lib/python3.13/site-packages (python 3.13)
```

If you do not have `pip` installed, see Install pip.

Installation

Install the AWS CLI v1-to-v2 Migration Tool in a new virtual environment:

```
$ python3 -m venv .venv
$ source .venv/bin/activate
$ python3 -m pip install aws-cli-migrate
```

Usage

Dry-run Mode (default)

With dry-run mode, you can automatically detect AWS CLI version 1 commands that are subject to breaking changes without modifying the input script:

```
$ migrate-aws-cli --script upload_s3_files.sh
```

Auto-fix Mode

With auto-fix mode, you can automatically detect and update AWS CLI version 1 commands in the input script to mitigate breakage from changes introduced in AWS CLI version 2, where possible:

```
$ migrate-aws-cli --script upload_s3_files.sh --fix
```

Optionally, you can supply an output path via the `--output` parameter to write the updated script, rather than updating the input script:

```
$ migrate-aws-cli --script upload_s3_files.sh --output upload_s3_files_v2.sh --fix
```

Interactive Mode

With interactive mode, you can automatically detect AWS CLI version 1 commands that are subject to breaking changes. Most findings will show a suggested fix to mitigate breakage in AWS CLI version 2. You can review the suggested fixes and decide whether to apply them. Optionally, supply an output path via the `--output` parameter to control where to write the updated script:

```
$ migrate-aws-cli --script upload_s3_files.sh --interactive \
--output upload_s3_files_v2.sh
```

The following output snippet is an example finding in interactive mode:

```
14 14#
15 15# aws s3 ls s3://mybucket
16 16#
17   #-aws s3 cp s3://amzn-demo-bucket s3://amzn-demo-bucket2 --recursive
```

```
   17#+aws s3 cp s3://amzn-demo-bucket s3://amzn-demo-bucket2 --recursive --copy-props
 none
18 18#
19 19# TEMPLATE_KEY="cloudformation/$(basename "$TEMPLATE_FILE")"
20 20#

examples/upload_s3_files.sh:17 [s3-copy] In AWS CLI v2, object properties will be
 copied
from the source in multipart copies between S3 buckets. If a copy is or becomes
 multipart
after upgrading to AWS CLI v2, extra API calls will be made. See
https://docs.aws.amazon.com/cli/latest/userguide/cliv2-migration-changes.html#cliv2-
migration-s3-copy-metadata.

Apply this fix? [y] yes, [n] no, [a] accept all of type, [r] reject all of type, [u]
 update all,
[s] save and exit, [q] quit:
```

The suggested fix is shown in a format similar to a Git diff. The migration tool suggests the removal of lines starting with a `-`, and suggests adding lines starting with a `+`. In the previous example, the suggestion can be interpreted as adding the `--copy-props none` parameter to the AWS CLI version 1 command that executes an Amazon S3 copy.

For each suggested fix, you can enter any of the following controls:

- Enter `y` to accept the suggested fix.
- Enter `n` to reject the current fix.
- Enter `a` to accept all fixes with the same type.
- Enter `r` to reject all fixes with the same type.
- Enter `u` to accept all remaining fixes.
- Enter `s` to save and exit.
- Enter `q` to quit without saving.

Some findings may be flagged for manual review without a suggested fix. You should review these findings and verify whether you are impacted by the referenced breaking changes. If you are impacted by these findings, you should follow the guidance specified in the finding description to make the necessary changes to avoid or prepare for the breaking changes introduced in AWS CLI version 2.

Limitations

The AWS CLI v1-to-v2 Migration Tool does not currently support every breaking change introduced with AWS CLI version 2, and has false positive cases where it outputs detections for commands even if no breaking changes would actually be faced.

We strongly recommend customers understand Breaking changes between AWS CLI version 1 and AWS CLI version 2 published in New features and changes in the AWS CLI version 2.

Text-based Analysis

The migration tool analyzes your script without running it. This limits how it detects AWS CLI commands for breaking changes. The migration tool can only examine the text of an AWS CLI command. It cannot detect issues that arise at runtime, such as storing deprecated parameters in a variable instead of passing them directly to the AWS CLI.

Unsupported Breaking Change Detection

The extent of support for breaking changes in the migration tool is summarized in the following table.

Breaking change	Detection supported	Auto-fix supported
Environment variable added to set text file encoding	No	No
Binary parameters are passed as base64-encoded strings by default	Yes	Yes
Improved Amazon S3 handling of file properties and tags for multipart copies	Yes	Yes
No automatic retrieval of `http://` or `https://` URLs for parameters	No	No
Pager used for all output by default	Yes	Yes

Breaking change	Detection supported	Auto-fix supported
Timestamp output values are standardized to ISO 8601 format	No	No
Improved handling of CloudFormation deployments that result in no changes	Yes	Yes
Changed default behavior for Regional Amazon S3 endpoint for `us-east-1` Region	No	No
Changed default behavior for Regional AWS STS endpoints	No	No
`ecr get-login` removed and replaced with `ecr get-login-password`	Yes	No
AWS CLI version 2 support for plugins is changing	No	No
Hidden alias support removed	Yes	Yes
The `api_versions` configuration file setting is not supported	No	No
AWS CLI version 2 uses only Signature v4 to authenticate Amazon S3 requests	No	No
AWS CLI version 2 is more consistent with paging parameters	Yes	No

Breaking change	Detection supported	Auto-fix supported
AWS CLI version 2 provides more consistent return codes across all commands	No	No

Uninstalling the AWS CLI version 2

This topic describes how to uninstall the AWS Command Line Interface version 2 (AWS CLI version 2).

AWS CLI version 2 uninstallation instructions:

Linux

To uninstall, follow the same method you used to install the AWS CLI.

Command line installer

To uninstall the AWS CLI version 2, run the following commands.

1. Locate the symlink and install paths.

   - Use the `which` command to find the symlink. This shows the path you used with the `--bin-dir` parameter.

     ```
     $ which aws
     /usr/local/bin/aws
     ```

   - Use the `ls` command to find the directory that the symlink points to. This gives you the path you used with the `--install-dir` parameter.

     ```
     $ ls -l /usr/local/bin/aws
     lrwxrwxrwx 1 ec2-user ec2-user 49 Oct 22 09:49 /usr/local/bin/aws -> /usr/local/aws-cli/v2/current/bin/aws
     ```

2. Delete the two symlinks in the `--bin-dir` directory. If your user has write permission to these directories, you don't need to use `sudo`.

   ```
   $ sudo rm /usr/local/bin/aws
   $ sudo rm /usr/local/bin/aws_completer
   ```

3. Delete the `--install-dir` directory. If your user has write permission to this directory, you don't need to use `sudo`.

   ```
   $ sudo rm -rf /usr/local/aws-cli
   ```

4. **(Optional)** Remove the shared AWS SDK and AWS CLI settings information in the `.aws` folder.

   > **Warning**
   >
   > These configuration and credentials settings are shared across all AWS SDKs and the AWS CLI. If you remove this folder, they cannot be accessed by any AWS SDKs that are still on your system.

   The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If your user has write permission to this directory, you don't need to use `sudo`.

   ```
   $ sudo rm -rf ~/.aws/
   ```

Snap

We provide an official AWS supported version of the AWS CLI on `snap`. If you used `snap` to install the AWS CLI, use the following steps:

1. Run the following `snap remove` command for the AWS CLI.

   ```
   $ snap remove aws-cli --classic
   ```

   If you used `sudo` to install the AWS CLI, you need to add it to the command.

   ```
   $ sudo snap remove aws-cli --classic
   ```

2. You might need to restart your command prompt window or your computer to remove all files.
3. **(Optional)** Remove the shared AWS SDK and AWS CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all AWS SDKs and the AWS CLI. If you remove this folder, they cannot be accessed by any AWS SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If you have write permissions to this directory, you don't need to use sudo.

```
$ sudo rm -r ~/.aws/
```

macOS

To uninstall the AWS CLI version 2, run the following commands, substituting the paths you used to install. The example commands use the default installation paths.

1. Find the folder that contains the symlinks to the main program and the completer.

   ```
   $ which aws
   /usr/local/bin/aws
   ```

2. Using that information, run the following command to find the installation folder that the symlinks point to.

   ```
   $ ls -l /usr/local/bin/aws
   lrwxrwxrwx 1 ec2-user ec2-user 49 Oct 22 09:49 /usr/local/bin/aws -> /usr/local/aws-cli/aws
   ```

3. Delete the two symlinks in the first folder. If your user already has write permission to these folders, you don't need to use sudo.

   ```
   $ sudo rm /usr/local/bin/aws
   $ sudo rm /usr/local/bin/aws_completer
   ```

4. Delete the main installation folder. Use sudo to gain write access to the `/usr/local` folder.

```
$ sudo rm -rf /usr/local/aws-cli
```

5. **(Optional)** Remove the shared AWS SDK and AWS CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all AWS SDKs and the AWS CLI. If you remove this folder, they cannot be accessed by any AWS SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If your user has write permission to this directory, you don't need to use sudo.

```
$ sudo rm -rf ~/.aws/
```

Windows

1. Open **Programs and Features** by doing one of the following:
   - Open the **Control Panel**, and then choose **Programs and Features**.
   - Open a command prompt, and then enter the following command.

     ```
     C:\> appwiz.cpl
     ```
2. Select the entry named **AWS Command Line Interface**, and then choose **Uninstall** to launch the uninstaller.
3. Confirm that you want to uninstall the AWS CLI.
4. **(Optional)** Remove the shared AWS SDK and AWS CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all AWS SDKs and the AWS CLI. If you remove this folder, they cannot be accessed by any AWS SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *`%UserProfile%\.aws`*.

```
$ rmdir %UserProfile%\.aws
```

Troubleshooting AWS CLI install and uninstall errors

If you come across issues after installing or uninstalling the AWS CLI, see the section called "Troubleshoot errors" for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "Command not found errors", the section called "The `"aws --version"` command returns a different version than you installed", and the section called "The `"aws --version"` command returns a version after uninstalling the AWS CLI".

AWS CLI user guide document history

The following table describes important additions to the *AWS Command Line Interface User Guide*, beginning in January 2019. For notification about updates to this documentation, you can subscribe to the RSS feed.

Change	Description	Date
Account-based endpoint support added to the AWS CLI version 2	Account-based endpoints using your AWS account ID are now supported in the AWS CLI version 2.	March 20, 2025
Account-based endpoint support added to the AWS CLI version 1	Account-based endpoints using your AWS account ID are now supported in the AWS CLI version 2.	February 24, 2025
Updated credential and authentication information.	Updated credential and authentication method instructions and examples. This includes updating relevant Getting started pages and configuration pages. To accommodate this increase in documentation, relevant credential topics were moved to the new Authentication and access credentials section.	March 31, 2023
Token provider configuration with automatic authentication refresh for AWS IAM Identity Center added	The new process to configure the AWS CLI to authentic ate users with AWS IAM Identity Center (IAM Identity Center) using the SSO token provider configuration, which	December 7, 2022

	can automatically retrieve refreshed authentication tokens.	
Official Amazon ECR Public image for the AWS CLI version 2 released	The official supported Amazon ECR Public image for the AWS CLI version 2 is released for Linux, macOS, and Windows.	November 18, 2022
Updated the guide for migrating from AWS CLI V1 to V2	Expanded the breaking changes guide to include migration instructions to going from AWS CLI version 1 to the AWS CLI version 2. Includes updates to the Troubleshooting page to help with installation issues.	May 13, 2022
New process to build a AWS CLI installer from source.	New process to install or update from source to the latest release of the AWS CLI on supported operating systems.	February 17, 2022
Content for the AWS CLI V1 and V2 are now separated into their respective guides	For clarity and ease, the AWS CLI version 1 and AWS CLI version 2 content is now separated into their own guides. For AWS CLI version 1, see the AWS CLI version 1 User Guide.	November 2, 2021

Added AWS CLI alias information	Added AWS CLI alias information. Aliases are shortcuts you can create in the AWS Command Line Interface (AWS CLI) to shorten commands or scripts that you frequently use.	March 11, 2021
Updated filter output information	Updated information for filters and moved to their own page.	February 1, 2021
Added information for Wizards	Added AWS CLI version 2 wizard information.	November 20, 2020
Updated auto-prompt	Updated the AWS CLI version 2 auto-prompt information with current features.	November 10, 2020
Added Amazon S3 scripting example	Added an Amazon S3 lifecycle scripting example.	October 15, 2020
Added Amazon EC2 scripting example	Added an Amazon EC2 instance type scripting example.	October 15, 2020
Added retries information	Added a retries page for features and behavior of retries in the AWS CLI.	September 17, 2020
Server-side and client-side pagination page	Updated pagination information and centralized on a single page.	August 17, 2020
Updated s3 commands page	Updated the high-level s3 commands page with new examples and resources.	July 30, 2020

Updated installation information	The install, update, and uninstall information for Linux, macOS, and Windows are updated.	May 19, 2020
Added information for text file encoding on the AWS CLI version 2	By default, AWS CLI version 2 uses the same text file encoding as the local. You can now use environme nt variables to set text file encoding.	May 14, 2020
Official Docker image for the AWS CLI version 2 released	The official support Docker image for the AWS CLI version 2 is released for all Linux, macOS, and Windows.	March 31, 2020
Added information regarding client-side pagers for AWS CLI version 2	By default, AWS CLI version 2 uses the pager program `less` for all client-side output.	February 19, 2020
AWS Command Line Interface (AWS CLI) Version 2 is officiall y released	The AWS CLI version 2 is generally available and is the recommended version for customers to install.	February 10, 2020
macOS installer for AWS CLI version 2 is now an Apple Package installer `.pkg` file.	The macOS installer for AWS CLI version 2 has been updated from a `.zip` file with a shell script to full macOS Installer package. This simplifies installation and makes it compatible with the newest macOS releases.	February 3, 2020

Added content for AWS CLI version 2's improved default handling of S3 and STS Regional endpoints	By default, AWS CLI version 2 now directs requests for the Amazon S3 and AWS STS services to the currently configured Regional endpoint instead of the global endpoint.	January 13, 2020
Developer preview release for AWS CLI version 2	Announcing preview release of AWS CLI version 2. Added instructions about installin g version 2. Add Migration topic to discuss differences between versions 1 and 2.	November 7, 2019
Added support for AWS IAM Identity Center to AWS CLI named profiles	AWS CLI version 2 adds support for creating a named profile that can directly login to IAM Identity Center and get AWS temporary credentia ls for use in subsequent AWS CLI commands.	November 7, 2019
New MFA section	Added a new section describin g how to access the CLI using multi-factor authentication and roles.	May 3, 2019
Update to "Using the CLI" section	Major improvements and additions to the usage instructions and procedures.	March 7, 2019
Update to "Installing the CLI" section	Major improvements and additions to the AWS CLI installation instructions and procedures.	March 7, 2019

Update to "Configuring the CLI" section	Major improvements and additions to the AWS CLI configuration instructions and procedures.	March 7, 2019
